Buv lasers

265-350nm

TUNABLE DYE LASER from Electro-Photonics offers a choice of output from 265nm to about 350nm. This is o-tained by frequency doubling the output from a flash lamp pumped dye laser giving a visible output in the TEM_{oo} mode of a few mJ with a pulse width of approximately 350ns.

325nm

HELIUM-CADMIUM LASER from Liconix can give over 5mW in the UV. Three models are available giving output at TEM_{oo} of 1.0mW, [redacted]mW and 5mW. These lasers can be fitted with an interchangable set of mirrors to give outputs up to 18mW at 441.6nm.

337nm

NITROGEN sealed gas laser from Laser Energy can be pulsed up to 100Hz to give average powers of 20mW. Each pulse has an energy of 200μJ with a pulse width of about 10ns. This system can be used to pump the Laser Energy dye laser giving a tunable output between 370 to 650nm.

We sell many other lasers and laser accessories.

Ecological Implications and Mechanisms of Compensation

Effects of Temperature on Ectothermic Organisms

Edited by Wolfgang Wieser

With contributions by W. Wieser, K. Y. H. Lagerspetz, M. N. E. Harri, Ch. Winter, J. R. Hazel, P. W. Hochachka, V. Pye, E. Wodtke, L. G. Johnson, R. C. Newell, H. W. Behrisch, B. Heinrich, I. D. Marsden, P. E. Coyer, C. P. Mangum, B. L. Bayne, R. J. Thompson, J. Widdows, K.-G. Collatz, E. Pattee, C. Lascombe, R. Delolme, J. N. R. Grainger, U. Halbach, A. Buschinger, H.-J. Braune, I. F. Spellerberg, H. Theede, W. Kirchner, H. Stöver

126 figures
XI, 298 pages. 1973. Cloth DM 66,—; US $27.10
ISBN 3-540-06420-6
Prices are subject to change without notice

The study of the way ectothermic organisms react to temperature continues to produce insights that are relevant to a number of general biological problems. For example, the application of temperature changes as a research tool has revealed that the modulation of enzyme activity by cofactors and changes in membrane permeability are amongst the basic mechanisms controlling adaptive processes.
The first section of this book presents the most important recent findings and speculations about responses to temperature in ectotherms and heterotherms.
The second section looks at temperature as an ecological factor and analyzes some of the subtle ways in which it controls biological processes in ectotherms (which represent some 95 % of the organisms living on the Earth).

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (*a*) is preferred to e^a if '*a*' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963–65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. The artwork of published papers can only be returned if a self-addressed envelope is enclosed.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Chips with everything

THE science of human nutrition in Britain has fallen on hard times. Of that, even the practitioners themselves seem to agree. In the last war the nutritionist played a major and acknowledged role in keeping the public healthy (some would say healthier than ever before or since). These days scientists turn their noses up at the thought of becoming nutritionists and the public gets little or no advice on what constitutes a balanced diet—apart from keeping cigarettes out of it. The situation seems to be worse, if anyting, elsewhere in Europe.

Nutrition is not an easy subject to define, as it includes so many aspects of other disciplines. Nevertheless it may be helpful to make subdivisions such as

(i) clinical nutritionists dealing with individual cases and counselling at the individual level,

(ii) scientific nutritionists working, say, on vitamins, fortification or dietary assessment techniques,

(iii) epidemiological nutritionists handling the statistics of large populations and

(iv) public nutritionists working either with government or the food industry on monitoring and information.

Who becomes a nutritionist? It is here that the problems start. There is no prescribed way into the field, but a broad biological education, probably with a medical background, is desirable. However, the job lacks kudos and the attraction of the microscopic and submicroscopic in biology draws away many talented students from study of the whole man. In medical schools, nutrition is about on a par with chiropody in appeal to students, and, for lack of good teachers, has often been introduced incidentally in other courses. A clinical nutritionist will often find himself a different title such as endocrinologist. As a result, those in nutritional departments of universities find it extraordinarily difficult to recruit high-calibre postgraduates, who regard the subject as soft and indefinite.

There is also a problem in the student's perception of a career structure. There are several senior posts in nutrition which will fall vacant in the next few years and there will be difficulty, it is said, in filling these, as there are insufficient middle level positions. Students see the lack of obvious upward steps from junior posts and they leave for better guaranteed careers.

Nutrition is very obviously a subject where the interplay between universities, industry and the public health services should be strong, but the deficiencies in career prospects in the academic sector have not been made up for by an adequacy of challenging positions elsewhere. The food industry does not employ many nutritionists (in contrast with the animal feed industry with its obvious interests in fatter beasts—the whole man may not be a proper study of mankind, but the whole pig certainly is). Those that industry does use are frequently engaged simply in ensuring the accuracy of labels or approving advertisements. Those in public service too often find themselves engaged in routine activities, whilst there are large public health educational issues which go untouched.

Obesity is a case in point. Many believe that this is the major nutritional problem facing the Western world today, not only in itself, but for the many disorders which spring from it. Yet at present next to nothing is being done by public health authorities either in prevention or cure. Nutritional counselling even of the simplest kind barely exists. And for health clubs or dieting systems claiming to reduce weight safely there is no public supervision. This at a time when the choice of foods available to the consumer is large and there is a demand for information on good eating habits.

There are, fortunately, signs of change. The recent establishment of two Royal Society Sainsbury Fellowships should go someway towards producing better prospects for career advancement. Further, there is an indication that a new generation of students has a greater interest in multi-disciplinary people-oriented biology. And the new administrative areas of the National Health Service should each have a 'community dietician'.

Much remains to be done, however, in the field of health education. The responsibility is ultimately the government's and the duty is to make the public aware of the elementary principles of sound nutrition so that more sophisticated choices can be made when buying food. It has long been a British principle to assume that intuition is a good substitute for understanding, and therefore that detailed information about the nutritional properties of food is unnecessary. It is time that such an attitude was superseded.

The results of better nutritional counselling would be unspectacular, and there would be inevitable doubts that a long-term educational programme would have any more impact than have anti-smoking campaigns. This should not deter government from taking a few inexpensive steps in the right direction. They would at least stimulate a greater commitment to nutritional studies by the food industry. In turn, this might breathe more life into research in the universities.

100 years ago

A PETITION signed by twenty-six Professors in the Universities of Scotland has been presented to the Prime Minister, calling his attention to the treatment of the ladies admitted to matriculate as students of medicine in the University of Edinburgh, and afterwards refused the right to graduate, and urging the Government to take the whole subject of the University education of women into consideration, with the view of devising a remedy for the present anomalies.

From *Nature*, 10, 16, May 7, 1874.

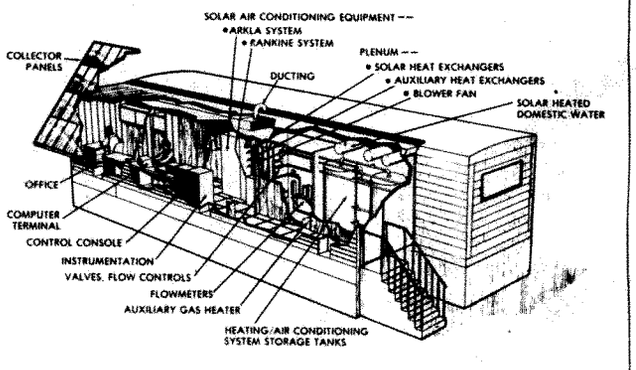
Cold comfort from Friends

In a recent letter to the Secretary of State for Energy, Mr Eric Varley, Friends of the Earth (a charitable organisation committed to the conservation, restoration and rational use of the ecosphere) drew attention to the energy savings possible through improved insulation standards and urged that he encourage the introduction of measures which would put an end to unnecessary waste. Here Christine Thomas, a researcher with Friends of the Earth, describes the sort of savings which might be made with a policy for insulation.

Friends of the Earth recently spent a Saturday insulating the roofs of the homes of some 40 old age pensioners throughout the country. They did so in order to draw public attention to the waste caused by heat loss through poorly insulated buildings—an estimated 75% of the energy consumed for space heating in homes insulated to present standards.

Improved insulation can drastically cut this loss; domestic fuel consumption for heating could be reduced by as much as half while still maintaining the same degree of comfort, or indeed improving it. Such savings matter most for those on small or fixed incomes—in particular the elderly, whose health and incomes can least withstand excessive fuel bills. According to a recent national study about 6 million old people are living in rooms clearly too cold for comfort, between 500,000 and 700,000 of them having unacceptably low body temperatures: clearly candidates for hypothermia.

It was facts like these that prompted the Friends to join with Age Concern (the National Old People's Welfare Council) in a practical gesture to demonstrate the ease with which insulation standards could be improved. Laying glass fibre or mineral wool in an attic costs perhaps £20, and offers at present prices a fuel cost saving of some 16% a year in the average semidetached house. Cavity walls can be filled with a variety of foams and mineral substances; solid walls can be faced with insulating board; windows can be double glazed. An average investment of £300 would cover improvements to the roof, walls and windows, together with draught exclusion, cutting fuel consumption by almost a half. Such a sum can be recouped in less than 10 years by the concomitant savings. Double glazing, however, forms a disproportionately large part of this cost, by comparison with the heat loss it can prevent. Something like a reduction of 35% in fuel consumption can be achieved by increasing roof and wall insulation alone at a cost of around £100.



Since domestic heating accounts for 20% of the total energy consumed in Britain, the potential national saving would be about a tenth of the present amount of energy used, the equivalent of nearly 11 million tonnes of oil each year. Calculations show that the power demand that would be eliminated by such a reduction is some 38,000 MW, equivalent to the combined output of some 50 large nuclear reactors. It would, of course, be expensive to insulate existing housing to these standards; a sum of the order of £5,000 million would be required. This, however, compares favourably, with for instance, the capital cost of the power stations that would otherwise be needed: at least £10,000 million. Thus there could be a saving of more than £5,000 million in the long run, not to mention savings in environmental and social costs associated with the installation of large scale generating plant.

It would clearly be far cheaper to insulate all homes fully than to build unnecessary power stations purely to supply heat to waste. Furthermore, by thus relieving some of the pressure on present energy supplies, a very important breathing space would be gained: time to look closely at genuine energy requirements and how they can best be fulfilled, time to develop alternative sources of power, sustainable and safer sources.

The improvement of insulation standards is an area of energy conservation readily amenable to legislative encouragement. Minimum levels for new dwellings are set in the Building Regulations by stipulating the maximum values of U (a measure of the conductivity) permitted. The regulations are at present made under the Public Health Act, which stipulates that they can only be made with specific reference to considerations of health and safety. There is argument as to whether present standards are adequate even for this limited purpose, and proposals for amendments are at present being considered. This, however, seems as far as the present regulations can be pushed.

In order that higher standards, justifiable in terms of energy savings, can be set, the scope of the Building Regulations will have to be widened. This was discussed under the Heath administration when the Department of the Environment was promoting Part III of the Health and Safety at Work etc. Bill, which would have empowered the Secretary of State to make regulations specifically "furthering the conservation of fuel and power" (III, 61, 2, b).

At the discretion of a Local Council, Home Improvement Grants may at present be given for some upgrading of insulation. But the position is not clear; people are unaware of the possibility and many councils are reluctant to give such grants. Making insulation the subject of a Standard Grant would dramatically improve the availability of money; and, together with a positive campaign of public education to ensure that people took advantage of the scheme, would go a long way towards improving standards.

A TRANSPORTABLE laboratory to collect data on incoming solar energy and to carry out advanced research on solar energy heating and cooling systems under widely varying climatic conditions across the United States is completing tests in the Washington, D.C. area before beginning active experiments. The laboratory, housed in two large trailers, was taken to the Washington area for calibration and evaluation of its experimental systems and weather instrumentation at the National Bureau of Standards at Gaithersburg, Maryland. A major purpose of the research with the laboratory will be to obtain correlation of solar energy systems with local requirements which vary widely over the United States. In line with this purpose, local groups of designers, architects, building contractors, and zoning and building code officials in communities along its route will visit the laboratory to exchange information with researchers on specific needs in adapting such systems for use in their localities.

international news

Where freedom is an academic issue

AFTER seven months of junta rule in Chile academic life is stagnating. On the morning of the Allende government's overthrow in September the military occupied all of the country's nine universities, installed their own representatives in place of the deposed rectors, ordered mass suspensions of students and staff alike, and began a process of 'cleansing'. The result of this process is that those members of the academic community who avoided execution, torture or imprisonment, and who have not managed to join the thousands who fled the country, remain at the universities in puppet roles organising resarch according to the junta's decree, teaching what the junta thinks fit to be taught. If they were unfortunate enough to be working in the social sciences their chances of ever again doing academic work in their own country look remote. Even the Christian Democrats who balked at Allende's politics are now coming under fire, and as if the initial physical brutalities were not a sufficient token of the junta's intentions, Chile is being treated to a spectacle which makes clear its new rulers' attitudes to intellectual life: the burning of books.

Immediately after the coup the new regime closed most faculties and departments in the social sciences, history and philosophy. In the University of Concepcion 6,000 of the 16,000 students and hundreds of academics were suspended; the eastern campus of the University of Chile in Santiago was closed and over 8,000 students had their studies cut short, while 4,500 students and 100 academics in the university's school of fine art, music and architecture were suspended.

The Technical University in Santiago, where there was a massacre of students the day of the coup, has been changed into a "military polytechnic" and all of the students and teachers (about 20,000 students in all) have been expelled. All adult education programmes have been stopped. This puts an end to the educational schemes for workers that were carried out under the Popular Unity Government. It is estimated that 5,000 members of the Chilean academic community have fled to Mexico, and 1,000 to France, while smaller groups have escaped through foreign embassies to other European countries and to North and South America.

In Britain, where refugees had been welcomed with open arms from Czechoslovakia in 1968 and Hungary a decade earlier, there was official reluctance to mount a welcoming party for exiles who were themselves communist, or at least capable of living and working without complaint under a communist system. The removal of the Conservative government (one of the first to recognise the junta) in theory makes the way easier for Chilean academics looking for a base to re-establish their careers, but in fact only a handful have so far been accepted: 19 postgraduate students, two undergraduates and 14 visiting and research fellows.

An educational charity, the World University Service has joined with a pressure group called Academics for Chile in raising funds for displaced academics, and together they have produced more than £20,000 and pressed the British government for a contribution. The official response is that already £100,000 is being paid out in training and technical assistance to more than 70 Chileans, most of whom were in the country at the time of the coup, when aid was available on a government to government basis. The Department of Overseas Development is thought to be looking for new ways of continuing this aid now that a socialist government is in the driving seat.

Meanwhile, accounts of the average non-political academic's predicament at the time of the coup and since can be had at first hand in almost any university town in Europe. One such academic who left Chile after repeated harassment by the military and is now studying at a British university, recalled his experience in the following terms (his name is withheld because of his fears for relatives remaining in Chile):

"When the military government took over one of their first targets was the universities. On the day of the coup, the military occupied all nine universities in Chile and the Technical University in Santiago was bombed. The junta considered the universities the main focus of the social change that had swept the country since President Allende's government had come to power in 1970, and they seized power to put a stop to it.

"Their attention was especially concentrated on departments of economics, sociology, anthropology and history as these had been in the forefront of social change, with increasing emphasis being placed in the last few years on social research and educational projects in the shanty towns and amongst the workers and with increasing numbers of workers being given grants to study at the universities.

"After the coup the new government imprisoned many intellectuals even from the right-wing Catholic University in Santiago, and many are reported to have been tortured or executed. The rectors of all the universities were replaced by members of the armed services, and special 'prosecutors' were assigned to each department to hear information and charges placed against students and lecturers by informers.

"Many thousands of students and lecturers suspected of Marxist or socialist ideas who had escaped imprisonment were sacked, and in March all lecturers had to resign and reapply for their jobs. The appointments boards are appointed by the military rectors and the case of those lecturers sacked or refused reappointment on political grounds is grave. There is at present little hope of them being able to find other jobs in Chile, even as manual workers, as employment contracts are strictly scrutinised by the military authorities and no-one who has lost his job for political reasons can be re-employed.

"Whole university departments have been closed down, and I have heard of one department of social sciences where the whole department was imprisoned for publishing research on conditions in the shanty towns and in the country areas.

"As for myself, I was taken from my house by soldiers with no charges being made, and taken to the army barracks. There I was stood against the wall, guarded by four soldiers, for several hours before being interrogated. Already I found, the army had collected all my personal details and previous publications and activities, probably I thought from informers. I was accused of being a Marxist on the basis of my writings, but my interrogators obviously had no idea what Marxist philosophy really consisted of. I found it impossible to put up a legal and rational defence as the whole legal and moral basis of action had been overturned

and actions and writings which had been previously considered perfectly legal were now retrospectively considered illegal, such as not taking part in the anti-Allende demonstrations and strikes before the coup.

"I was interrogated ten times in all, and eventually I left the country rather than risk the alternatives of imprisonment, suspension or of being allowed to continue teaching only courses approved by the government.

"These restrictions in education have reached down as far as the primary schools, and in my opinion the military government is trying to turn the clock back in their educational policies by stopping grants for workers to study at the universities and by strictly controlling the matter and methods of teaching. The restrictions now being placed on freedom of speech are becoming intolerable to most intellectuals, even to those Christian Democrats who opposed Allende and had welcomed the coup."

The reference in this account to the overturning of the legal and moral basis of action is echoed in a further report from Dr H. M. Gerschenfeld, a signatory to a letter about the plight of Chilean academics published in *Nature* in March. According to the military government's Law no 111, suppressing the legal governing bodies of universities, 34 professors of the University of Valdivia were expelled without right of defence, says Dr Gerschenfeld. In some cases the professors were offered the alternative of resigning, and if they refused to do so, they were expelled.

Among more serious casualties of the new order were Professors Merio Ramirez (Education) and Jorge Pena (Music), shot at La Serena; Dr Enrique Paris, secretary of the University of Santiago, died while undergoing torture; Professor Kirkberg, rector of the Technological University of Santiago, imprisoned on Dawson Island.

As for institutions which have suffered under the junta, Dr Gerschenfeld writes as follows:

"The destruction of the departments of psychology and sociology occurred in essentially all of the universities in the country. Even internationally supported schools such as the well known Facultad Latino-americana de Ciencias Sociales (FLACSO) was closed. The Institute of National Studies (CEREN) of the Universidad Catolica at Santiago was also dismantled. Seventy to 100% of the faculty members in the departments of geography, literature, fine arts, history and geology were removed from their positions in Santiago.

"The authorities of the universities who were nominated by the military government also expelled a large number of students on the grounds of sympathising with the government of Dr Allende. The data are fragmentary, but the examples are indicative: for instance, of the 254 first year students of the Science School at Santiago, 174 were expelled, at Concepcion, of 70 students in the last year of the medical school, only 10 were readmitted after a selection on political grounds.

"The number of scientists, teachers, and professional people who are leaving Chile is so great that the military junta has become alarmed. There have been rumours in the last month that the government will impose a tax of 3,000 to 5,000 American dollars to each person having a university degree who wants to leave the country, even if they have been expelled from their jobs at the university or elsewhere. We could not confirm this directly, but the appeals for help from our Chilean colleagues mention this menace and urge the European scientific community to do something for them."

An idea of the lengths to which the military government will go in order to interfere with the career of an academic whom they consider hostile is illustrated by the experience of Juan Rada, who at the time of the coup was a third year student of the sociology of education at the Catholic University of Santiago. Rada had played an active part in the running of the university as a student representative on the higher council. He was a known supporter of Allende's social change programme, and within days of the junta's takeover he stood up and spoke against the military rulers during a meeting of the higher council. He received a phone call during the night (from one of the regime's supporters as it happened) warning him that the junta had decided he was dangerous.

Rada sought refuge in a foreign embassy, and since he was unable to obtain a safe conduct he left the country by a route which he prefers not to disclose—although he is prepared to describe a fast car ride to the airport with motor-cycle outriders. He arrived in Britain earlier this year, and since he had not actually sat his final exams at the time of the coup he asked permission to qualify at London University. When the university wrote to Chile in order to learn about Rada's academic record there they were told that nobody of that name had ever been at the Catholic University of Santiago. As far as the university where Rada had served on the higher council was concerned, he had never existed. Rada was able to establish his bona fides, and to take his exam, and he is now a postgraduate member of London University's Department of the Sociology of Education. He is in touch, regularly, with former colleagues who remained in the country. Their reports, he says, add up to a single message: "Intellectual life is dead."

Business report

John Gribbin and Roger Woodham

Gordon and Breach Science Publishers Inc., of New York, have filed a petition under Chapter XI of the United States Bankruptcy Act. The company's 1973-74 list contains 85 journal titles, most of them scientific; but, according to the management of the British subsidiary of the company, production has not been affected by the filing.

The G & B petition itself follows a similar petition filed under Chapter XI of the Bankruptcy Act by a subsidiary, Media Directions Inc., on November 2, 1973. According to a representative of the British company, the petition now filed by the American parent on March 29, 1974, was necessary "to protect the parent from repercussions from that action".

The Managing Director of the British-based operation — a wholly owned subsidiary of the American parent says that "production, promotion, distribution and other publishing operations are not affected by the filing, and subsidiaries of the American company are not involved. I should stress that we intend to continue our normal publication of journals and new books."

The first meeting of the G & B creditors was held in New York on April 24, before Bankruptcy Judge Edward J. Ryan. The proceedings were adjourned until May 13. Under American law it is possible for a company to bring the court and creditors into the running of that company without ceasing to trade.

According to figures circulated to major creditors by attorneys for the $4,161,297 and 21 cents, while assets total $2,302,940 and 84 cents including an item of $2 million for "stock in trade".

● "THE most significant new product range in the history of the company" was how Mr Ralph Price, chairman of Honeywell in the United Kingdom, described the new Series 60 computers when they were launched last week. Only time will tell whether Honeywell has the upper hand when companies like ICL and IBM unveil their models for the late 1970s and early 1980s in the next year or two.

Honeywell's total turnover in 1973 was $1,170 million, and the profit before tax was $93 million. Although not actually disappointed with the growth of sales in the past year or two, senior management at Honeywell hope that sales will grow faster with the Series 60.

The advent of Series 60 is a positive move on Honeywell's part towards the marketing of fewer, but more flexible, pieces of hardware and software. The new range builds on the best of

Russians seek joint facility in Australia

Peter Pockley, Sydney

Six weeks after the new Australian-Soviet science agreement was initialled in Canberra, it has been revealed that the Russian delegation which finalised these arrangements proposed at the same time that 'a joint scientific facility' be established in Australia. Although this was essentially a renewal of a previous proposal in 1971, the recent press stories caused a flurry of comment in the Parliament and diplomatic circles. There was reportedly a reaction from the United States Ambassador who was said to be concerned that the proposed 'facility' could be a threat to the various American defence bases in Australia.

Of these, two are in the big league —the naval communications base at North-West Cape (Western Australia) and the military satellite station at Pine Gap in the centre of the continent. A security screen surrounds the operations of these stations and there was immediate speculation that the Russians were 'trying out' Australia's diplomatic commitment to the American alliance by indirectly setting up a facility which could conceivably also act as an electronic monitor of American activities.

Both the Prime Minister, Mr Gough Whitlam, and the Foreign Minister, Senator Don Willesee, were, however, at pains to emphasise that no decision had yet been made and that the proposed facility—to be managed jointly by both nations—would be 'to photograph space objects and to contribute to atmospheric studies'. It is not, as reported by some news agencies, intended to be a tracking station The proposal is now being studied by various departments before Mr Whitlam's planned visit to Moscow in the middle of the year.

For readers in the Northern Hemisphere, who have become accustomed over decades to continual contract with the Soviet Union of a military and diplomatic kind, the sharp Australian reaction to such an apparently mild proposal may seem excessive. But, rare though it is in the Southern Hemisphere, even remote possibilities of direct influence by the Soviet Union on events here have always been greeted by over-reaction.

The most celebrated example in recent times was the case of Vladimir Petrov, a Russian diplomat-cum-spy operating out of Canberra, whose defection in 1954 was turned to long lasting political advantage over his Labour opponents by the then Prime Minister, Mr Robert Menzies. The first Russian scare occurred, rather extraordinarily, in the Crimean War when the new settlers actually built harbour forts in a show of self-reliant bravado against the imaginary invaders from the steppes.

The present concern has been a two-day political wonder but it has its roots in the fears of a possible buildup of Soviet naval power in the Indian Ocean on Australia's undefended western seaboard of about 2,000 miles. As with the Australian-Soviet science agreement itself, this latest matter was treated by politicians and press alike as primarily a diplomatic affair, with science as the passenger in the vehicle.

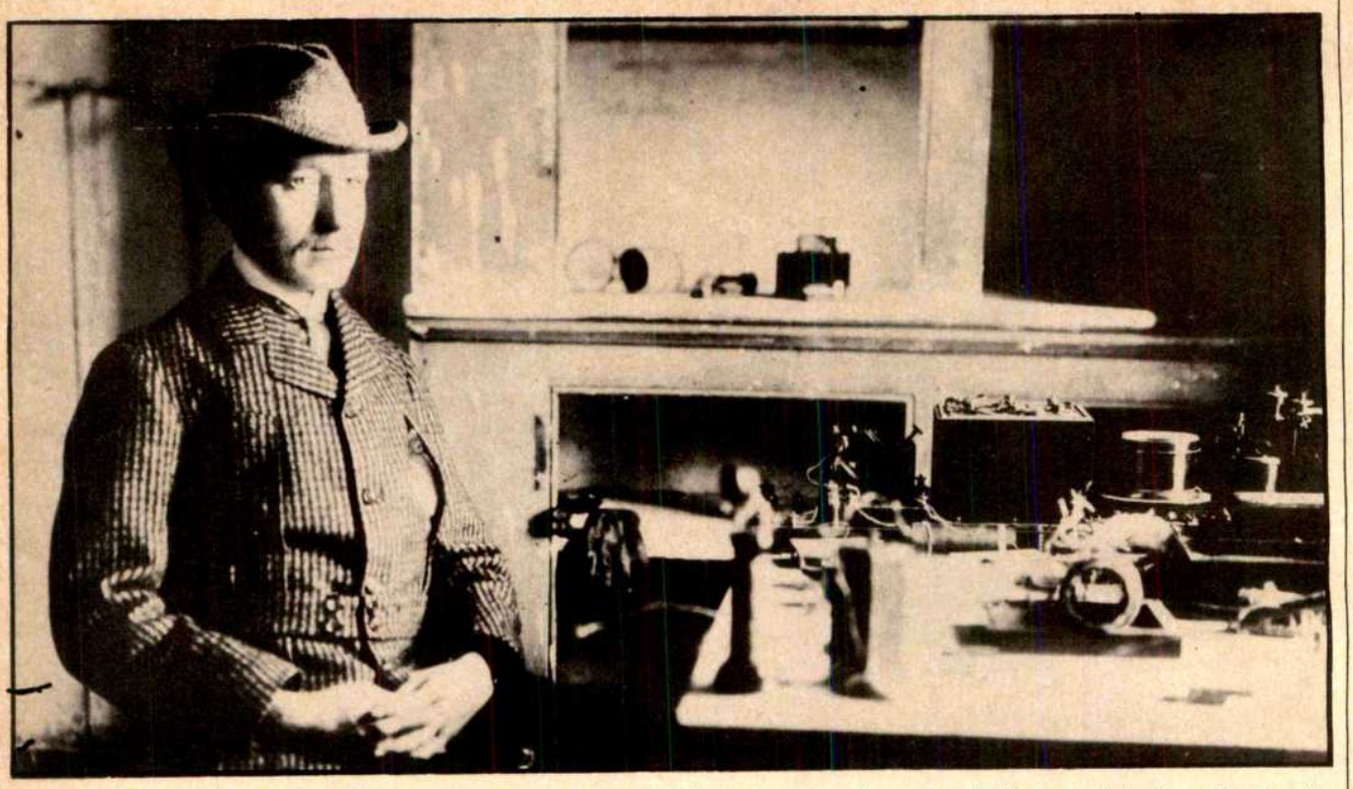
Honeywell's present lines and those of the erstwhile computer arm of General Electric (USA) which Honeywell took over three-and-a-half years ago. At that time Honeywell and General Electric actively marketed 10 computer series, 20 processors and 12 software systems —now there are just four, eight and six. The largest of the new series, Level 66 is based on the Honeywell Series 6000 which has brought in about $1,000 million since it was launched in 1971.

The development costs for the new series have hardly been trivial; most of the $50 million earmarked for development by Honeywell in each of the past three years has gone on the Series 60, and much of the development work was done in Europe. (Level 66 computers are, indeed, to be manufactured at the Honeywell factory in Newhouse, Scotland.)

Honeywell says that the Series 60 will be suited to existing computer users and newcomers alike. Prices for Level 66 systems start at £450,000—of £10,000 a month on a rental basis—but Honeywell do have relatively small companies and organisations in mind for the less sophisticated Level 61 which costs £22,000+£400+a month). Honeywell is using the phrase 'attack machines' to describe the Level 61, for it sees many potential customers buying this as their first computer, possibly to do such mundane jobs as stock control.

Cash problems for public interest law

Colin Norman, Washington



SINCE they first rose to prominence in the late 1960s, public interest law firms have made an impressive contribution to the development of government policies in the United States, ranging from the regulation of food additives to the protection of the environment. Staffed by a handful of lawyers and supported chiefly by philanthropic organisations, they have provided the cutting edge of the environmentalist movement and in many cases have formed an effective counterforce to the big business lobby which traditionally dominates the Washington political scene.

But they are now facing the prospect that one of their largest single sources of funding, the Ford Foundation, may withdraw its support in the next couple of years and put its money elsewhere. Ford has been pumping millions of dollars into public interest law since the 1960s, and since it traditionally provides seed money for the establishment of projects, rather than financial support over long periods of time its withdrawal from the field has long been anticipated.

Some idea of the influence of the foundation on the field of public interest law can be gauged from the fact that it provides between 85 and 90% of the budget of the Center for Law and Social Policy, the law firm which was in the forefront of the legal battle against the trans-Alaska pipeline and which have been effective in setting standards for treatment of the mentally retarded. The foundation also contributes some 40% of the operating funds of the Natural Resources Defense Council, which has won several landmark court victories against the Environmental Protection Agency and which argued the law suit which eventually forced the Atomic Energy Commission to publish an environmental impact statement on the liquid-metal fast-breeder reactor programme.

Faced with such the prospect that their funds may dry up, many of the law firms are exploring possible new financial arrangements which will put their activities on a sounder footing and provide them with a more permanent source of funds.

Two recent events have brought the matter to a head. The first is that last week the Ford Foundation announced that it will provide four of the largest firms with $2.3 million to finance their activities at least until the end of 1975 but it accompanied the announcement with the statement that Ford's role after the grants expire "cannot be determined now". And the second is that the Ford Foundation itself convened a conference in San Diego in

Marconi at Signal Hill, Newfoundland, in 1901 with instruments used to receive the first trans-Atlantic wireless signal.

THE Science Museum, London, is commemorating the centenary of Marconi's birth with an exhibition which opened on April 25. This is more likely to appeal to someone with a keen interest in wireless or in the history of science than to the casual visitor; the most interesting exhibits are letters and other literary material which are clearly presented and easy to read, but require time to digest.

Other exhibits emphasise the social rather than the scientific significance of wireless, with pieces of original equipment (including the kite used to fly the aerial from which the historic transatlantic broadcast of December 12, 1901, was made) and personalia including Marconi's swordstick.

One of the curiosities on show is a copper earthing tube dug up in the 1960s from the garden of the bungalow where Marconi lodged in 1896–97; the tube was in the ground outside Marconi's old room and was probably used by him in his earliest experiments in Britain.

But the written and printed matter is by far the most interesting. A cutting from the *New York Times* of February 13, 1927, reports Marconi's views about the prospects for wireless transmission of power, "radio movies" and television. He was rather optimistic about the latter, and the reporter looks forward to the day when "Secretary Kellogg (sits) in his office in the State Department and converses face to face with Premier Baldwin in Downing Street". In other ways, Marconi was equally visionary, foreseeing the replacement of oil as a fuel source by solar energy, but dismissing the idea of tapping geothermal power because heat from the Sun is both a simpler and cheaper source.

By 1932 (according to the *Daily Mail* of December 6) Marconi's vision had expanded still further. Musing that messages could be sent on further than around the Earth, and prompted by the interviewer, he said: "Interplanetary communication—who can tell? There is a great deal more to be found out and made perfect."

John Gribbin

mid-April to discuss possible new arrangements for financing the firms.

Although the foundation has made it clear that the firms should be thinking seriously about how they should live without Ford money, it is equally clear that if it came to the crunch, Ford would be unlikely to pull the rug from underneath public interest law firms and allow them to expire or cut back their operations drastically. Thus the emphasis will be on finding new sources and methods of finance.

Two possible arrangements were suggested in the San Diego meeting and, although no concrete decisions were taken, at least two possibilities were given careful consideration and hold great promise. One idea is to set up a permanent fund, financed by private donations, philanthropic organisations and perhaps even by professional legal organisations. Such a fund would probably operate much like a foundation, but the way in which the money would be distributed has not yet been worked out.

Another possibility is that courts will award legal fees to public interest law groups which successfully sue the government and industry. But the problem there is that the acceptance of such fees could well endanger the firms' legal status as tax-exempt organisations, and until the Internal Revenue Service issues some guidelines on the matter the firms are precluded from taking such fees. Ironically, some major pieces of environmental legislation, such as the Clean Air Act, and the Federal Water Pollution Control Act contain specific provisions which direct courts to award attorneys' fees to organisations which successfully bring court cases against the government, but until the IRS gets round to issuing its guidelines, those fees cannot be awarded to public interest groups.

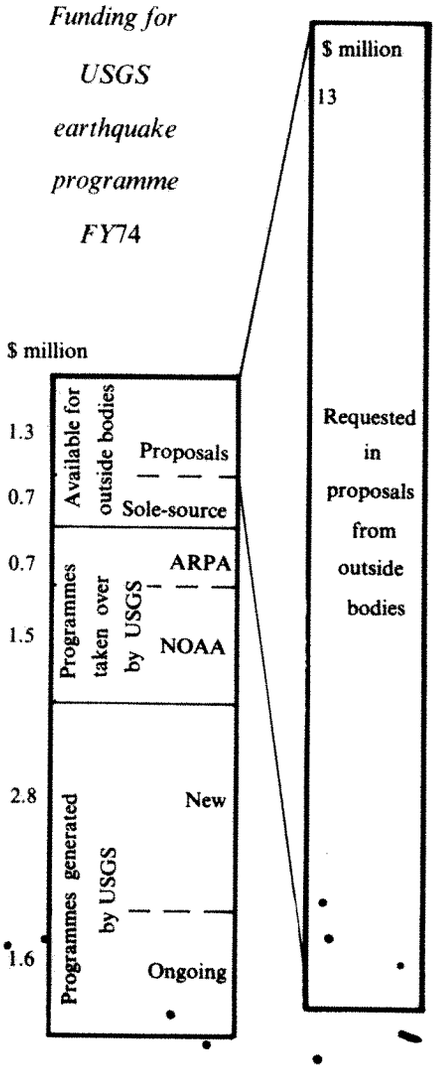
Thus the next couple of years could be critical for the future of an extremely important element in governmental decision making in areas which have a profound effect on scientific matters.

Quake prediction no bonanza

David Davies

In the late 1960s travellers' tales suggested that Russians were having some success in detecting premonitory symptoms to earthquakes. Physical properties of rocks in Central Asia were said to change prior to quakes, although Western geophysicists, deeply immersed in plate tectonics and lacking any sight of the Russian data, were not moved to do much. Then in 1972 American interest suddenly grew explosively. By early 1973 precursors to earthquakes had been seen in many parts of the world, a dilatancy theory had been proposed to explain the observations and a simple relationship between the duration of the precursor and the size of the earthquake had been suggested. The annual American Geophysical Union meeting in April 1973 was a heady experience. This year's meeting was sober by comparison, and there was much concern about funding.

The situation is a classical one of what one could call the four black spots of present day science policy:



- Too many people chasing too little money.
- Government, industry and universities working in the same field.
- The political need for a mission-oriented approach in conflict with scientists' desire for in-depth understanding.
- The problem that the contractural system poses for the university scientist.

On the scientific side, it had been a relatively quiet year. There had been two instances, one in New York State, the other in Riverside, California, where events had been foretold by means of variations in seismic wave travel times before the earthquake. The same technique was also showing some promise in other places, although there seemed a growing feeling that the quality of data was often inadequate and that the near-focal conditions are vastly more complex than a first modelling would suggest. On the other hand there is promise both in gravimetric and tilt observations and some of the laboratory and field experiments (including earthquake control by fluid injection) have gone well.

Responsibility for the American 'earthquake hazard reduction programme' is vested in the US Geological Survey (USGS). Much more than prediction is covered—risk analysis, mapping and rock mechanics are other fields of activity. In the fiscal year July 1971-June 1972 (FY 1972) the programme amounted to $1.6 million, but the impact of the San Fernando earthquake put up the allocation to $4 million by FY73. In moving into FY74, the first year in which prediction could be discussed seriously, the USGS found itself picking up responsibility for earthquake work previously done by the National Oceanographic and Atmospheric Administration (NOAA) and fluid injection studies of the Advanced Research Projects Agency (ARPA). Thus although the budget for FY74 was $8.6 million, by no means all the increase was in the form of new money for research. The figure shows the distribution. Apart from sole-source contracts—for instance to support seismic networks operating at present, universities, state governments and industry had $1.3 million to fight over. No increase is seen in this sum for FY75. "We need a big earthquake to shake more money out of the government" as one official put it.

The figure of $1.3 million took many by surprise, as it was generally expected that in the mid-1970s the USGS would dispense the largesse that in the past had come from ONR, NASA, NSF and ARPA and which had made for so many thriving geophysical laboratories. External funding applications for FY74 amounted to $13 million from two hundred proposals—the USGS is able to support 32 of them. On one official's reckoning it could have intelligently used $8 million this fiscal year. Expertise is going unused, he thinks. As it is, some seismic stations in California have already closed for lack of funding. Other agencies no longer have a charter to do research in this field, so failure with the USGS really does mean failure to fund. The prediction programme is a very lean operation in which immediate relevance is necessary of every project. "A hard-nosed mission-oriented approach" as one project officer described it—himself with a modest fame as having already engendered such an approach in three other government agencies.

Funding for USGS earthquake programme FY74

It is inevitable that there is conflict in such an underfunded situation. More generalised and global research suffers at the hands of the more particular and American. There is a suspicion that the USGS will swallow up all the good ideas that come from outside (university scientists pointedly remark that the first good papers in the subject came from MIT, Stanford, Columbia and Caltech, not the big government laboratories which now have most of the available money). And, most immediate, people in universities suddenly find themselves up against government contracts officers, zealous to ensure scrupulous accounting. It is this more than anything else which seems to have persuaded rational men that they are being persecuted. The staff of the USGS are aware of these undercurrents of bitterness and are trying to establish better headquarters procedures.

There are some very obvious defects at the moment and action needs to be taken at governmental level (university scientists are also going to have to learn to live with the system a bit more). The lack of funds is quite ludicrous. The United States loses on average $630 million annually through earthquake damage—a figure which will doubtless go up when California next suffers a serious quake. To keep talent out through lack of one-hundredth of that sum is a false economy. Worse, it is worrying that the programme is required to be so nationally oriented (the USGS is, of course, part of the Department of the Interior). Most countries look to their own scientists to solve their own problems, but the Western world has increasingly looked to the United States to grapple with global problems, at risk of being branded imperialists. If ever there were a problem knowing no frontiers this is it, and success would be that much more likely if more American geophysicists could be financially encouraged to think and collect data in a more global framework.

Russians at conferences

SIR,—"Have the Russians arrived?" International conference-goers will know how the question passes from one to another as they assemble at the start of the meeting. The uncertainty of whether the Soviet delegation will appear or not (and if they appear, on which day?) has long provided a touch of drama for the other participants and a headache for the organisers. The first clue for the organisers is often a message from the travel agency acting for Intourist that they are asked to book hotel accommodation for so many Soviet delegates. The names may not be known, only the total number, and the scientific contact with them will commonly not be direct but through some official Soviet committee or authority.

I have recently returned from an international conference abroad where this scenario was duly re-enacted, but this time I experienced it directly as I had to preside over the meeting. Writing now in my private capacity, not as president, I have to report sadly that nothing has changed; it is as bad as ever.

We had asked a prominent Soviet scientist, let us call him Professor Y, to give one of the specially invited review papers and our invitation was accepted. As the time drew near the secretary of the meeting wrote to him several times to ask about his paper, but with no reply. Telegrams were tried, and then many telephone calls to Moscow. Professor Y was unknown to them, they said; or, Professor Y had gone away. Faced with this concerted silence, we began to fear for our colleague. Finally, four days before the opening of the conference we received a telegram from Professor Y that his paper would be presented on arrival. (All the other papers for the conference had already been reproduced for distribution.) Our hopes rose, but we remembered the old Russian proverb "Do not sell the bearskin until you have shot the bear." The Soviet delegation, expected to be twelve, turned out to number seventeen, including the usual chaperone from Intourist, and Professor Y was not among them. They bore with them copies of his paper for distribution and a verbal message from him asking me to present it. I did so, believing that my colleague was in no way to blame for these bizarre events and wishing to help him in his difficulties as much as I could (the rules of the conference just allowed it). It is worth adding that some or all of the five extras in the Soviet party did not have enough foreign currency to pay the fee and so were unable to be registered for the conference.

The Soviet authorities who are responsible for these things should realise that this sort of behaviour on their part is harmful to Soviet science. Organisers of conferences already think twice before inviting papers from Soviet authors, knowing the uncertainties that will result. We should like to include them, on equal terms with the others, but how can we go on doing so in face of this continued official discourtesy to the scientific community?

Yours faithfully,

J. D. NYE

H. H. Wills Physics Laboratory, University of Bristol, UK

Great crested grebes

The Zoological Society of London

Darwin's omission

SIR,—I wish to draw the attention of historians of science to the omission by Darwin (in his *Origin of Species* and even in his *Selection in Relation to Sex*) of any mention of cases where the two sexes are similar in plumage. Sexual selection for Darwin involved the choice by females of brighter, and often larger, males. Darwin presumably did not have the opportunity to study sexually similar species: once he returned to Down House he was not able to observe freshwater or marine birds.

The same omission occurs in the books on evolution by Ernst Mayr, in Barnard Rensch's *Evolution above the Species Level* and, strangely enough, in the early edition of my own *Evolution, the Modern Synthesis*. I say strangely, for in the years 1914 to 1917, I myself had described the elaborate mutual display of grebes, herons and egrets; and later returned to the display of swans, albatrosses, and penguins, which had been studied in detail by others. The first account of mutual display was given by E. Selous in 1901–02, and by myself in 1914; in both cases, of great crested grebes (*Podiceps cristatus, Proc. zool. Soc. Lond.*, 1914). My failure to mention mutual display in my book seems to have been due to my not realising its frequency or its biological value in strengthening the emotional bond between members of a pair. This point emerges clearly from the work of Lorenz and Tinbergen.

I wish to stress the strikingly different results of unilateral and mutual display, in regard both to display characters and to behaviour. A regular feature of mutual display is that the returning bird presents the sitting mate with nest material (in grebes a similar presentation occurs on open water). Another feature of mutual courtship is the extent of ritualisation; but this also applies to many male unilateral displays where the sexes have different plumage, as in bustards, pheasants, some grouse, and so on. Today the importance of ritualisation has been confirmed: see the Royal Society's symposium on Animals and Man (*Phil. Trans. R. Soc.*, 1966).

The red breast in both sexes of the robin (*Erithacus rubecula*) is not connected with courtship: Lack has shown that the colour is a mark of territorial ownership, for both sexes have winter territories. In dimorphic species the songs of males, and of 'duetting' birds such as some African Shrike, are also proclamations of territory.

Yours faithfully,

JULIAN HUXLEY

31 Pond Street, London NW3, UK

Rat race

SIR,—a recent advertisement emphasises the present crisis in biology laboratories, where research is severly hampered by the shortage of experimental animals. "A position of Wissenschaftlicher Rat is vacant" in Freiburg (*Nature*, March 1, xx; 1974); applicants should have experience of cell-mediated immune reactions.

Yours faithfully,

B. JOVE

Hove, UK

news and views

Transferring foreign genes to plants

It is well established that purified DNA can be taken up by bacteria and that the recipient cells are capable of incorporating DNA into their chromosomes and expressing the genes thus acquired. Attempts to perform similar experiments with eukaryotes, however, are often viewed with scepticism although an increasing number of workers are investigating this problem.

In their simplest form these experiments involve the use of two closely related organisms which differ with respect to an easily identifiable phenotypic characteristic. Attempts are then made to transfer this character to individuals that lack it by applying purified DNA from the appropriate donor. The experiments of Hess involving white and red flowered plants of *Petunia* fall into this category (Hess, *Z. Pflanzenphysiol.*, **60,** 348-358; 1969; **61,** 286-298; 1969; **63,** 461-467; 1970; **68,** 432-440; 1973). In some instances the test organism has a deficiency in an essential metabolic pathway and corrected individuals are selected by their ability to grow without the appropriate nutritional supplement. In many experiments the donor DNA is derived from organisms totally unrelated to the recipient and evidence for uptake and possible incorporation into host chromosomes has been obtained. Occasionally bacteriophages have been used as an enriched source of specific genes and there is evidence for the synthesis of enzymes coded for by the phage DNA (Carlson, *Proc. natn. Acad. Sci. U.S.A.*, **70,** 598-602; 1973).

To establish that true transformation is possible in eukaryotes, it is necessary to study the fate of applied DNA by biochemical techniques, to show that changes in the recipient organism are directed by the donor DNA and to demonstrate that these changes are inherited. Ledoux and his colleagues have been carrying out some of these experiments for more than a decade and have obtained some remarkable results (Ledoux and Huart, *Eur. J. Biochem.*, **23,** 96-108; 1971). In this issue they present data which suggest that thiamine deficiency in *Arabidopsis thaliana* may be corrected by bacterial DNA and furthermore that this correction can be inherited.

Arabidopsis is particularly suitable for such experiments. It is comparatively small and easy to manipulate and grow aseptically and it flowers within a few weeks of germination. Ledoux and his team used a number of lines with lesions in the branched pathway for thiamine biosynthesis. These plants normally require either exogenous thiamine, pyrimidine or thiazole for continued growth and reproduction but they found that a small number of the plants grew and produced seed in the absence of supplements after they had been treated with the appropriate bacterial DNA.

Ledoux states that DNA with a molecular weight in excess of 10^7 is necessary and the DNA solution should be applied to the ungerminated seeds during imbibition. DNA-corrected plants grow more slowly than supplemented mutants and only about one third of those that grow actually produce seed. The observed frequency of correction can be as high as 10^{-2} compared with a spontaneous reversion rate of the *Py* locus of less than $\cdot 5\times10^{-6}$, and $4\times^{-5}$ for reversion induced by ethyl methane sulphonate. DNA from phage T7 and 2C is ineffective and DNA from *Escherichia coli* unable to produce the thiazole moeity of thiamine does not correct the corresponding *Arabidopsis* mutant although it is effective with plants deficient in the pyrimidine pathway.

Seeds from corrected plants were germinated and selfed to produce F_1 to F_3 progeny. Although these plants showed some variegation in chlorophyll content no typical thiamine-deficient segregants were observed. This suggests that the parental lines are homozygous which is a rather surprising result although it should be noted that Hess observed a similar situation with *Petunia*. Ledoux suggests that in the case of *Arabidopsis*, during meiosis and afterwards, the gametes containing the information for thiamine production are favoured over mutant gametes. In support of this proposal he cites the finding that if during DNA correction plants showing signs of abortive flowering are supplemented with thiamine then lethal mutants appear in the F_2. Although this result would also be expected in the absence of applied DNA, in this case no corrected plants would be anticipated. In crosses between progeny of DNA-corrected plants and either wild type or mutant individuals, lethal mutants and a variety of leaky mutants are obtained. There is no evidence for cytoplasmic inheritance of the corrected character.

Obviously the mechanism involved in these DNA-mediated corrections is of major interest, but it would be premature to attempt a deailed interpretation. From the figures quoted by Ledoux the frequency with which the corrections are obtained is too high to be explained by spontaneous reversion of the mutation. On the other hand direct evidence for the synthesis of a bacterial enzyme in these plants is not available at present. Other experiments by the Mol group suggest that foreign DNA can become integrated in some way into plant DNA although the significance of these findings has been questioned (Hotta and Stern, in *Informative Molecules in Biological Systems* (edit. by Ledoux) 176-178, North Holland; 1972). One thing is certain; experiments of this nature hold out intriguing possibilities and they will continue to generate interest and occasionally heated discussion.

From our Plant Cell Physiology Correspondent

Number of cells at the time of X activation

ALTHOUGH female mammals possess two X chromosomes, in any particular adult cell only one of these homologues is active, providing a dosage compensation which ensures that females and males both display the same number of active-X-linked genes. The fertilised egg and very early embryo of eutherian mammals, including man and mouse, possess two active X chromosomes; that one of these two chromosomes is randomly inactivated in each cell at an early stage of genetic development was first suggested by Lyon (*Nature*, **190,** 372; 1961).

The random nature of the process is suggested by the expression of sex linked genes in adult females. In heterozygotes in which one X chromosome carries a wild type and the other carries a mutant allele, those cells in which the wild type X chromosome is active must show wild phenotype whereas cells instead possessing the active mutant X chromosome display the mutant phenotype. One visible

consequence of this random inactivation is the variegation seen in the coats of female mice heterozygous for X-linked coat colour genes. The equal representation of wild and mutant phenotypes, and the presence of patches of each coat colour, suggest that at the time of decision in the early embryo, in each cell one X chromosome (chosen at random) remains active whereas any others are inactivated (in animals possessing several X chromosomes only one stays active). In the subsequent divisions of genetic development, the state of each homologue is faithfully reproduced; the adult cells descended from any particular embryonic cell after the time of decision therefore constitute a clone characterised by the presence of the same active X chromosome (with the exception of the germ cells in which both X chromosomes remain active).

Two critical questions to ask about genetic development in eutherians are therefore: when does X activation take place; and what is the basis for its random nature? The closest estimate of the time of decision derives from the work of Gardner and Lyon (*Nature*, **231**, 283; 1971) with chimaeric mice. Instead of the usual complete fusion between two embryos, they injected a cell taken from a blastocyst into another blastocyst. Because the donor and recipient carried different gene markers for coat colour, any cells in the adult coat descended from the injected embryonic cell can be distinguished. Since donor sex-linked markers showed variegation in the heterozygous condition, X activation must take place after the blastocyst stage (otherwise the donor cell would have suffered previous X activation and its descendents would all be of one phenotype in the adult).

By taking advantage of a mutant which influences the random nature of X activation, Ohno and his colleagues (*Cell*, **1**, 175; 1974) have recently developed an ingenious approach to estimate the number of cells in the embryonic mouse at the time of decision. Their experiments rely on the concept that the clonal composition of embryos immediately after X activation can be expressed as the binomial $(p+q)^n$, where n is the number of cells and p and q are the probabilities of activation of each chromosome, both equal to 0.5 in the wild type animal. In other words, given a population of animals it is possible to predict the frequencies with which any particular clonal composition will be generated. Unfortunately, this formula cannot be directly extrapolated to the adult animal, because distortions in the initial clonal composition must inevitably take place as the embryo grows; for only some, and not necessarily a random selection, of the embryonic cells will be utilised during formation of each adult clone. The formula which determines the clonal composition of an adult phenotype must therefore be written as $(p'+q')^{n'}$, where n' is the number of progenitor cells from which the adult clone is descended, and p' and q' have values corresponding to the relative frequencies of each active X chromosome in the set of progenitor cells—and this, of course, in turn depends upon the clonal composition of the embryo from which the progenitor cells are descended.

Because these changes in cell composition make it impossible to determine n directly from the adult phenotypes, Ohno *et al.* have used a special situation to allow this analysis. In one particular condition only, changes in cell composition cannot occur during development; this is the case when all the copies of one X chromosome (either the maternal or paternal) were by chance activated. This generates a monoclonal embryo, which can in turn give rise only to monoclonal adult. But these two extreme cases each occur with a very low frequency (0.5^n); as Ohno *et al.* point out, this creates the paradox that, even given a value for n as low as 20, such fractions would occur with frequencies too low determine by experiment in any researcher's lifetime (of the order of one in a million mice). To achieve a more manageable situation, they therefore utilised a mutation of the X chromosome (0^{hv}), which they have previously characterised, and which causes preferential activation of the X chromosome carrying it in heterozygotes where the other chromosome is wild type (*Nature new Biol.*, **245**, 92; 1973; *Cell*, **1**, 3; 1974). The 0^{hv} mutation seems to be an extreme version of alleles at the Cattanach's "controlling element" locus which maps in the middle of the mouse X-linkage group; and earlier analyses of chromosomes carrying this allele have suggested that the mechanism of decision is for one X chromosome to be activated whereas any others in the cell are inactivated (reviewed by Brown and Chandra, *Proc. natn. Acad. Sci. U.S.A.*, **70**, 195; 1973).

When the 0^{hv} X chromosome carries the mutant gene *Blo* and the other X chromosome carries the corresponding wild type allele, regions of the coat of the mice are light coloured if derived from cells in which the 0^{hv} *Blo* X chromosome was activated, and are dark if derived from cells in which the wild type X chromosome was activated. Because of the preferential activation of the 0^{hv} X chromosome, the frequency of occurrence of mice with coats largely of *Blo* phenotype is appreciable. To obtain values for the occurence of two, rather than just one, of the possible clonal compositions, in addition to assessing the proportion of mice with coats derived entirely from *Blo* cells, Ohno *et al.* also determine the frequency with which mice displayed coats almost entirely of *Blo* phenotype, but with just one dark spot (corresponding to one coat progenitor cell in which the wild

BL Lac identified with giant galaxy

THE peculiar object BL Lacertae seems to lie at the centre of a normal giant elliptical galaxy. This identification provides an estimate of the distance to BL Lac, and this in turn suggests that the central source is similar in spectral index and luminosity to QSOs such as 3C48, 3C279 and 3C345, provided those objects are at the distances indicated by a cosmological interpretation of their redshifts.

Those are the principal conclusions reached by Oke and Gunn as a result of a four year study of BL Lac (*Astrophys. J. Lett.*, **189**, L5; 1974). The observations were made with the multichannel spectrometer attached to the 200-inch telescope; some of the observations were made using a disk with diameter 5″ and a surrounding ring with inner diameter 10″ to study the extended regions of the source while obscuring light from the bright central feature, and these showed Hβ in absorption at a redshift of $z = 0.07$.

Other data support this redshift estimate, and show that the galaxy is one of the most luminous known, with a magnitude of about −23. Together with the growing evidence of similarities between BL Lac and QSOs this identification is one of the key advances of recent years. Far from being a blueshifted QSO, as had seemed possible, BL Lac can now be fitted into the cosmological picture of receding QSOs quite satisfactorily. The distance to the source is some 350 Mpc, and this raises the same questions about its energy generation mechanisms that apply for very remote QSOs. The energy requirements are extreme, but as Oke and Gunn say "It is interesting, however, that the same phenomena at approximately the same level of outrageousness exist for BL Lac as for higher-redshift QSOs if they are placed at the distances suggested by their redshifts". J. G.

type X chromosome was activated).

These frequencies should have been determined by the clonal compositions of the cells which provide the immediate progenitors for the coat, that is they depend on the formula $(p'+q')^{n'}$, and so provide experimental values for the frequencies of the fractions $(p')^{n'}$ and $(p')^{n'-1}.q'$. To relate these values to the initial clonal compositions at the time of X activation (that is to p, q and n) requires knowledge of n'. Given a value for n', it is then possible to test various combinations of p, q and n to see which values would generate cell populations from which animals monoclonal for the coat would be produced at the observed frequency. This involves summing several possible situations, since, for example, a monoclonal coat may arise not only whenever the original embryo was monoclonal but also whenever the progenitor cells of the coat by chance were descended only from cells with an active 0^{hv} X chromosome; when the number of immediate progenitor cells is sufficiently large, the entirely mutant adult phenotype should occur only in individuals which started their development with very one sided clonal compositions.

The *Blo* mutation is therefore particularly well suited to such analysis, for the development of the cells in which it is expressed has previously been studied in some detail. *Blo* acts in mesodermal cells of somite origin, thought to result from the reproduction of 35 pairs of somite clones distributed along both sides of the vertebral column (Lyon, *Phil. Trans. Roy. Soc.*, **B259,** 41; 1970), suggesting a value for n' of 70. Animals with coats entirely of the *Blo* phenotype are too rare to measure in appreciable frequency, so Ohno *et al.* measured the frequency of occurrence of animals with a coat one half of which (corresponding to one side of the vertebral column) shows the *Blo* phenotype. This frequency, 41 in 2400 or 1.7×10^{-2}, provides an estimate of the frequency of the class p'^{35}; the square of this frequency, 2.9×10^{-4}, can thus be taken as an estimate for p'^{70}.

This total frequency might be produced by several combinations of p, q, n. To decide upon the most likely, Ohno *et al.* utilised their estimate of the frequency of occurrence of the class $p'^{69}q'$, that is the proportion of animals with only one wild type clone apparent in the coat; this was 3 in 2,400 or 1.25×10^{-3}. Although the accuracy of this estimate is not great, because of the small number of animals involved, this value can usefully be compared with the estimate for p'^{70}. Taking both values into account, Ohno *et al.* were able to show that a close fit to the data would be produced by $p=0.8$, $n=60$. In other words, the 0^{hv} allele confers an 80% probability that its chromosome will be activated; and the number of cells in the embryo at the time of decision may be close to 60.

How accurate is this estimate and what further tests may be made of it? One assumption upon which these experiments rely is, of course, that all 35 pairs of somite cells arise independently from some undifferentiated pool and not from a smaller pool of cells which then multiply upto 70. It would be useful if this point could be confirmed in future. Given the comparatively small numbers of animals which can be examined under the experimental conditions imposed by this system, the measured frequencies must clearly be taken as approximations and not precise values; but the value for n of 60 cells is consistent with the previous suggestion that the time of decision is soon after the blastocyst stage. It is therefore likely that 0^{hv} influences only the decision on activation and does not change the time at which it is made. Increased accuracy for these estimates would obviously be lent by determining clonal compositions and thus values for p, q and n from some other adult phenotype. But these qualifications do not detract from the importance of this seminal study, whose sophisticated manipulation of the mouse system has provided a useful estimate for the cell number in a mammal when the decision is taken on X activation.

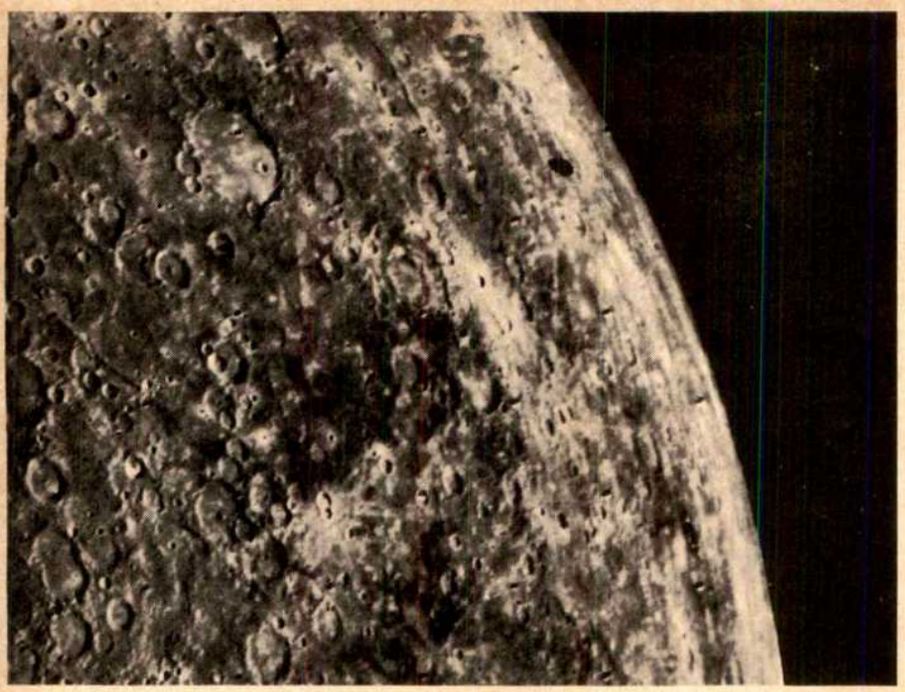
B.L.

More about Mercury

by our Cosmology Correspondent

MARINER 10 has done more than just send back some impressive pictures of Mercury, looking so very much like the Moon that one radio astronomer remarked recently that for all he knew they were in fact previously unreleased Lunar Orbiter photographs. The six non-imaging experiments on board the spacecraft have provided a new insight into the nature of the closest planet to the Sun, and this shows clearly how Mercury fits into the overall picture of the Solar System.

The photographs have, of course, contributed to this. The front cover illustration this week shows a region very similar to the terrain of the Moon, with a large, flat bottomed crater about 100 km in diameter (about the same size as the lunar crater Copernicus), linear grooves probably produced by crater ejecta, and so on. Together with pictures of Mars obtained by the Mariner series of spacecraft and by Soviet spacecraft, the latest NASA achievement emphasises the broad similarities between the inner planets of the Solar System. It now seems almost beyond doubt that Venus too will be found to be cratered and scarred by impacts and volcanic activity, although the evidence there may have been largely eroded away.



If the overwhelming impression of the visual evidence is that the inner Solar System forms a family of related planets, the non-visual data confirm this and indicate the way in which the distance of each planet from the Sun determines its individual characteristics within the family. Mercury turns out to be rather more massive than was expected, with a density of 8 g cm^{-3} implying that as much as two-thirds of it is composed of iron or iron group elements. The presence of a clearcut gradient in the densities of the planets in sequence outwards from the Sun obviously ties in neatly with the idea that more volatile elements condensed further out in the collapsing proto Solar System. And a large amount of iron could also explain the unexpectedly large magnetic field of Mercury. At some 200 to 300 gammas for the extrapolated strength of the field at the planet's surface, this is about 1% of the Earth's field; the favoured view at present is that this is a permanent field, and is not induced by a dynamo effect.

Among the other surprises already arousing interest is the discovery of a tenuous atmosphere around Mercury. This discovery will delight amateur astronomers, since reports that such an

Littorinid group

LITTORINIDS are present on the rock shores of all continents and present some intriguing taxonomic problems. The first symposium restricted to this family of the prosobranch Gastropoda was held at the Royal Scottish Museum, Edinburgh on March 19 under the chairmanship of Sir Maurice Yonge. Of the talks on taxonomic trends in the Littorinidae, perhaps the most noteworthy contribution was the evidence of J. Heller (University of Liverpool) that the polymorphic species *Littorina saxatilis* (Olivi) should be regarded as containing at least four separate species.

The meeting unanimously endorsed the suggestion that an informal littorinid group should be formed, with an international membership, as far as possible comprising all workers actively interested in these gastropods. Anybody wishing to learn more about the group should write to the appointed coordinator C. Pettit, Manchester Museum, The University, Manchester M13 9PL, England.

Southwestern quadrant of Mercury, viewed from Mariner 10 4 h before closest approach. Distance of spacecraft from planet was 198,000 km; the largest craters visible are some 100 km across. (NASA photograph.)

atmosphere could be seen have been made by members of that fraternity from time to time, but met with a cool reception from the professionals. Wise after the event, those professionals now say that such a tenuous atmosphere can be maintained, in spite of the low escape velocity from the planet, because of particles released through radioactive decay. Uranium releases helium (alpha particles), and potassium yields argon; another effect, capture from the solar wind, probably accounts for the presence of neon.

Clearly it will take a while for the new information to be digested and incorporated into theoretical models, and in September there is the prospect of more information as Mariner 10 passes by Mercury again. In the meantime, it is interesting to reflect on a comment attributed to Bruce Murray, leader of the Mariner 10 TV experiment team (*Aviat. Week Space Technol.*, **100** (14), 16; 1974), which indicates the rapid development of spacecraft systems and also answers the 'doubts' of that radio astronomer. The Mariner 10 pictures cannot be directly compared with Lunar Orbiter pictures, it seems, "because the Mariner 10 photos show more detail".

Models of growth and competition

from our Animal Ecology Correspondent

THE dynamics of competitive interaction between two species have long been the target of approximations. The formula

$$\frac{dN_i}{dt} = r_i N_i\,(1 - N_i/K_i - \alpha_{ij} N_j\,K_i)$$

(where N_i is the density of species i; r_i is the exponential growth rate of this species when its population density and that of its competitor j are low; K_i is the carrying capacity of the environment for species i when its competitor j is absent; α_{ij} is the linear reduction (of K_i) of species i's growth rate caused by its competitor j) has stood for more than 50 years since being proposed by Lotka (*Elements of Physical Biology*, Williams and Wilkins, Baltimore, 1924) and Volterra (*Leçons sur la Theorie Mathematique de la Lutte pour la Vie*, Gauthier-Villars, Paris, 1931). The model was validated in 1934 by Gause (*The Struggle for Existence*, Williams and Wilkins, Baltimore) who studied the dynamics of yeast and protozoan competition. The linearity of the model suited this kind of interaction. For arthropod interactions the model is less perfect. Gilpin and Ayala (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 3590; 1973) have recently put the model to the test using arthropod species and have come up with some important modifications.

Their competing species were *Drosophila willistoni* and *D. pseudoobscura*. Adult flies, in known densities, were put in culture vessels containing known amounts of food. After 1 week the surviving adults were counted, as were their offspring which emerged from the culture medium during the following 4 weeks. Zero isoclines, which depict the separation point between positive and negative population growth, were constructed from continuous populations, maintained by serial transfer. The single species equilibrium, or environmental carrying capacity, is the maximum population the culture medium can stand. As a competitor increases in abundance the zero isocline falls away from the maximum point. Where it intersects the zero isocline for the competitor species is the equilibrium point for the interaction of the two species.

The data from the *Drosophila* cultures were fitted to a large number of competition models chosen according to the criteria of simplicity, reality, generality and accuracy. The model that stood up best was

$$\frac{dN_i}{dt} = r_i\,N_i\,(1 - N_i/K_i)^{\theta i} - \alpha_{ij}\,N_j\,K_i)$$

The interpretation of the parameters is straightforward. r_i is the exponential rate of growth of species i when its density and that of species j is low; K_i is the carrying capacity of the environment for species i in the absence of its competitor j; α_{ij} is the reduction of growth rate of i as a result of the activities of j, and $\theta\,i$ denotes the asymmetry of the single species growth rate of species i. In the absence of competition, that is when $\alpha=0$, the growth rate conforms to the logistic. In other words the relationship between growth rate and density is parabolic. The point of maximum growth rate is $K/2$. The experimental data pointed out this restriction. The addition of θ removes it and allows the point of maximum growth rate to be less than, or more than, $K/2$.

This is an important modification to the Lotka-Volterra equation. Vertebrate populations in which growth rate tends to be controlled abruptly by the imposition of territoriality and other social factors cannot adequately conform to the continuously linear fashion demanded by the old model (when $\theta=1$). For them θ will tend to be larger than 1. Invertebrate populations, in which eggs, larvae and pupae are ignored, will tend to have a θ value less than 1.

Gilpin and Ayala propose this new model to encompass intraspecific and interspecific competition. Population ecologists shall have to wait before assessing its general applicability.

Biogenesis of chloroplasts and mitochondria

from a Correspondent

RECENT work on the biogenesis of chloroplasts and mitochondria was discussed at a symposium of the British Society for Cell Biology at the University of Warwick on March 28-29. Both

types of organelle are potentially autonomous, since they each contain DNA, DNA polymerase, RNA polymerase, and a protein-synthesising system, but all the evidence suggests that most organelle proteins are encoded in the nucleus and are synthesised by cytoplasmic ribosomes. The major problems discussed were the identification of the genes in the organelle DNA and of the proteins synthesised by organelle ribosomes.

The interactions between nuclear and organelle genomes in the synthesis of organelle proteins are complex, but are yielding to modern techniques. Two general principles are emerging: (1) one of the functions of the organelle DNA is to encode some subunits of multisubunit organelle proteins, the remaining subunits being encoded in nuclear DNA; (2) those protein subunits encoded in organelle DNA are synthesised by organelle ribosomes, whereas protein subunits encoded in nuclear DNA are synthesised on cytoplasmic ribosomes. For example, D. E. Griffiths (University of Warwick) reviewed data on yeast mitochondrial ATP-synthetase, which is composed of ten subunits; six of these are nuclear coded and made on cytoplasmic ribosomes, whereas the other four are made by mitochondrial ribosomes and are presumed to be encoded in mitochondrial DNA. The major chloroplast protein (fraction I protein or ribulose diphosphate carboxylase) is composed of large and small subunits. R. J. Ellis (University of Warwick) described the synthesis of the large, but not the small subunit, by isolated intact chloroplasts and by free chloroplast ribosomes. Tryptic peptide analysis of mutant tobacco plants has shown that the large subunit is encoded in chloroplast DNA whereas the small subunit is encoded in nuclear DNA. The emphasis of work in this area is now shifting away from the identification of products of the different genomes towards a study of the regulatory mechanisms existing between them.

Elegant studies of mitochondrial DNA isolated from cytoplasmic *petite* mutants of yeast were reported by P. Slonimski (CNRS, Gif-sur-Yvette); this DNA is derived from wild type DNA by large deletions which are replaced by reiterations of the non-deleted segments. The resulting gene redundancy can be detected by electron microscopic studies of half-denatured molecules. Stable *petite* mutants in which different parts of the mitochondrial DNA are repeated and amplified up to 100 times can be isolated, thus opening the way for the selective purification of different mitochondrial genes. Such studies on chloroplast DNA are much less advanced because of the difficulty of inducing mutations in the DNA of this type of organelle; R. Hagemann (Martin Luther University, Halle) reported that some naturally-occurring chloroplast mutations in higher plants are correlated with the absence of specific thylakoid proteins associated with photosystems I and II, and other mutations result in a loss of chloroplast ribosomes.

All of the products of protein synthesis by mitochondrial ribosomes, and most of those by chloroplast ribosomes, are membrane-bound. This raises severe problems of purification and isolation, but these problems are being steadily overcome. In a *tour de force*, R. O. Poyton (University of Connecticut) reported the isolation in milligram quantities of each of the seven subunits of yeast cytochrome oxidase. Four of these are made by cytoplasmic ribosomes and are water soluble when isolated, but the other three are made by mitochondrial ribosomes and remain insoluble. The three insoluble subunits are synthesised by isolated mitochondria, provided that oxygen is present; in anaerobic conditions, only one subunit is made. The mechanism of this interesting effect is unknown, but could reflect a specific effect of oxygen on mitochondrial transcription or translation.

On the second day, further work in the area of organelle biogenesis was discussed. G. S. P. Groot (University of Amsterdam) suggested from an analysis of base sequence homology in nuclear and mitochondrial DNAs of different yeasts that mitochondrial DNA evolves faster than nuclear DNA, and L. A. Grivell (University of Amsterdam) reported that yeast mitochondrial ribosomal RNA is extraordinary in its complete lack of ribose methyl groups and a very low level of base methylation compared with other ribosomal RNAs. A contribution on chloroplast RNA by M. R. Hartley (University of Warwick) was notable, in that it reported, for the first time, the detection of a specific messenger RNA from a plant source (other than a viral messenger). This messenger is for the large subunit of fraction I protein which can be correctly translated by a cell-free protein synthesising system from *Escherichia coli*. Studies of specific messenger RNAs from plants have lagged far behind those from animals, so this advance should open up a new area of plant molecular research.

Outstanding problems that were raised, but not resolved, were the function of the genes in chloroplast DNA, 90% of which are still unidentified, and the mechanism of the uptake of specific proteins into and across the outer membranes of mitochondria and chloroplasts.

Neural attenuation in echolocating bats

from our Animal Behaviour Correspondent

THE sonar system possessed by many bats enables them to perform such feats as flying unhindered through an array of fine wires and selecting one insect from a swarm of many. The echoes from surrounding objects must be perceived a few milliseconds after the bats have emitted an extremely intense outgoing sound pulse (often several thousand dynes per cm^2). Somehow the bats' ears must be protected from their own cries and yet still be sensitive enough to pick up the much fainter returning echoes. There are at least two mechanisms for accomplishing this. The muscles of the middle ear contract synchronously with vocalisation (they can contract and relax again up to 60 times s^{-1} on some species) and this has the effect of attenuating self-stimulation.

In addition to this peripheral mechanism, there are neural mechanisms of attenuation within the auditory pathways. Suga and Schlegel (*Science*, **177**, 82; 1972) made tape recordings of the calls of vespertilionid bats and recorded the response of a bat's auditory nerve both to this tape recording and to the same call when made by the bat itself. Although the response of the primary auditory nerves was virtually the same to both sorts of sound, the inferior colliculus (part of the mid-brain concerned with hearing) showed much less response to the live than to the tape-recorded sound. Attenuation, by some 25 dB, to the bat's own voice was occurring somewhere between the auditory nerve and this part of the brain.

Now Suga and Shimozawa (*Science*, **183**, 1211; 1974) have pinpointed the exact site of this neural attenuation. By recording from various nuclei along the auditory pathway when bats of the genus *Myotis* were either vocalising themselves or listening to tape recordings, they found that neural attenuation occurs in the nucleus of the lateral lemniscus. They point out that although such mechanisms are of obvious importance for bats with their special problems in echolocation, similar muscular and neural attenuation mechanisms may also operate in human speech, since our vocalisations rarely appear disturbingly loud.

Nuclear physics at Glasgow meeting

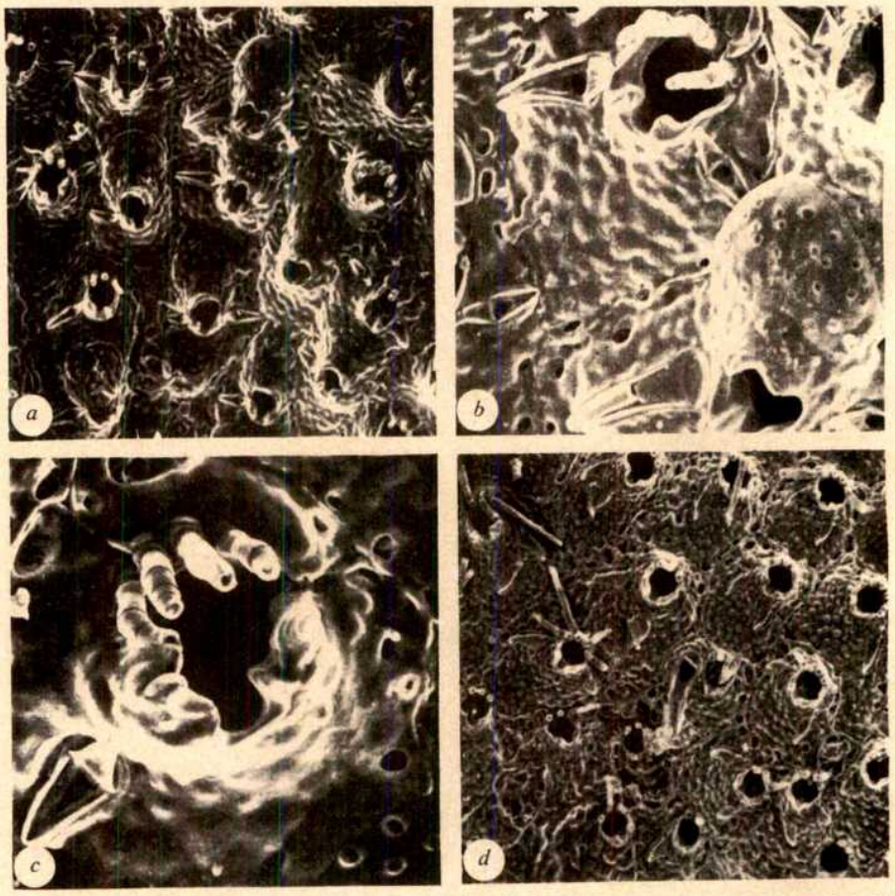
from a Correspondent

At the combined Institute of Physics conferences on nuclear structure and high energy physics, which took place at the University of Glasgow on March 27-29, the nuclear structure talks reflected in the main the specific interests of Glasgow workers. Experimental work in Glasgow concentrates on electron scattering, photoreactions and the use of photoreaction neutrons. The principal local activity in nuclear theory is the application of the shell model to fairly light nuclei.

E. Spamer (Technische Hochschule, Darmstadt) discussed the techniques by which the momentum resolution of the Darmstadt linear accelerator is being improved by a factor of five. He emphasised that this makes electron inelastic scattering applicable to the study of a great many more states than hitherto, at higher energies and in heavier nuclei. One would, for example, hope to learn more about the newly detected quadrupole resonance found above the familiar giant dipole resonance in medium nuclei.

R. Owens (University of Glasgow) dealt with photonuclear reactions in the higher energy region in which one hopes to obtain information about high momentum components in nuclear wave functions. This hope has been much deferred, and calculations with short range correlations seem at present to call for a further extension of the energy range in these experiments.

Short range correlations were also a feature of the contribution by J. M. Irvine (University of Manchester) who dealt with low lying levels of the p-shell nuclei. He has used a two-body interaction fitted to scattering deuteron data and a variational method applied to wave functions with both central and tensor correlation corrections, to obtain an effective interaction for use in a large basis shell model calculation with the Glasgow code. With reasonable restrictions on the short range central correlation, and by adjusting the strength of the tensor correlation to fit the absolute binding energy of each nucleus in turn, many other levels can be fitted with no further adjustment of parameters.



The talk by R. Arvieu (University of Paris, Orsay) also touched on the subject of large scale shell model calculations. He discussed the statistical approach to the shell model, in which one calculates the mean energy and moments of the level density distribution for various configurations. This can be used, for example to learn, in advance of investing in a large shell model calculation, which configurations are most essential and must be retained. H. A. Weidenmuller (University of Heidelberg) also discussed statistical aspects of nuclear physics, but in the more familiar context of the statistical model of neutron resonances. He emphasised that although statistical shell model calculations give the density of levels in a configuration in Gaussian form, as opposed to the semi-circle law of Wigner's random matrix model, the two models agree on the fine structure of the statistics of level spacings. The predictions of these models are well confirmed by data with up to 180 neutron resonances in a particular nucleus. Weidenmuller also discussed recent work at Heidelberg which extends the range of validity of the Hauser Feshbach prescription for average cross sections, and which allows effects of direct reactions to be allowed for in this method.

On the high energy side there was considerable emphasise on photon and lepton interactions although strong interaction physics, particularly at very high energies, also figured strongly. D. H. Perkins (University of Oxford) reviewed the experimental evidence for neutral currents in weak interactions and indicated that the experimental evidence is becoming steadily more convincing and is in good agreement with the Weinberg–Salam–Ward theory as opposed to the long standing Fermi theory which, as for example in beta decay, requires only charged currents.

Two examples of $\bar{\nu}_{\mu} e^-$ scattering have been recorded in the Gargamelle bubble chamber at CERN and many more events of the type ν+hadron $\rightarrow$ ν+hadron at both CERN and the National Accelerator Laboratory, Batavia (NAL).

Storage rings—both electron and proton—are producing results of fundamental interest and several speakers concentrated on data recently produced by these devices which allow observa-

Smittinid ectoprocts from Hawaii

The shallow waters round the Hawaiian Islands seem to be havens for the smittinid family of ectoproct bryzoans—the minute sedimentary aquatic animals which usually live in colonies. D. F. and J. D. Soule have found that the Hawaiian species of Smittinidae seem to be isolated specifically from the Indo-Pacific forms and that there are also species differences between the five major Hawaiian Islands. In a comparative study (*Bull. Am. Mus. nat. Hist.*, **152**, 365; 1973), the Soules recognise twenty-eight taxa of which two are new genera and twenty are new species. This figure shows (*a*) colony with tubular peristomes, (*b*) immersed ovicell and part of developing ovicell and (*c*) aperture with spines of *Parasmittina alanbanneri* n.sp.; (*d*) colony with spines on zooecia of *P. serrula* n.sp.

tion of collision between particles at energies hitherto unattainable by conventional accelerators.

J. Haissinski (University of Paris, Orsay) spoke about electron–positron storage rings where e^+e^- collisions at centre of mass energies of several GeV are studied. From the study of such collisions two main conclusions may be drawn: the first concerns quantum electrodynamics—the fundamental theory which describes the interaction between electrons, muons and photons—which is found to be still valid at distances as short as a few hundredths of the proton radius. Second, electron–positron annihilation processes can lead to the production of hadrons (strongly interacting particles such as pions, protons, neutrons) and production rates have proved to be unexpectedly high. If this trend persists at higher energies it would have important consequences as far as 'elementary' constituents of the hadrons are concerned. These hypothetical fundamental constituents (quarks) are now the object of an intense programme. The storage ring experiments seem to indicate that either these quarks form a rather large family, or that they have a structure of their own. In the latter case, the situation would be quite similar to the one which resulted from the discovery of the internal structure of the nucleons in the 'elementary' constituents of the nuclei.

The experiments currently taking place at the intersections of the Intersecting Storage Rings at CERN were reviewed by M. G. Albrow (CERN). Searches are being made for new exotic particles which may be produced at the very high centre of mass energies available at the ISR (up to ~ 56 GeV). Searches for quarks, magnetic monopoles and intermediate vector bosons have all so far proved negative although antideuterons have been observed. The important discoveries at the ISR of a 10% rise in the total pp cross section and of structure in the angular distribution of elastic scattering are now being measured with higher precision and studies of interactions where particles are produced with high momentum transfer relative to the incident proton direction are also proceeding. The observed high rate of such events would indicate the existence of point like constituents (partons) within the nucleon.

The current interest in nucleon substructure was also reflected in talks by R. G. Moorhouse (University of Glasgow) who dealt with photo-and leptoproduction processes in the context of the quark model and by F. Close (CERN) who described how the number of quarks in a particle can be determined by means of the energy dependance of the elastic scattering cross section at large angles.

Out of the ball park

from a Correspondent

At the Spring meeting of the British Biophysics Society, devoted to nucleation, folding and interaction of biopolymers, held at the University of Newcastle upon Tyne on March 26-28, and organised by Dr R. H. Pain of the Biochemistry Department, the policy was continued of devoting the major part of the programme to long (50 min) papers. In discussion the extent to which the various specialist techniques used to study biopolymers should be regarded as mutually complementary rather than competitive became very clear. A further impression was the way in which improvements in instrumentation and access to computers have facilitated more sophisticated interpretations of data from techniques such as ultracentrifugation and gel chromatography on complex systems of interacting biopolymers, and the rigorous testing of these interpretations by computor modelling of the experimental data.

R. L. Biltonen (University of Virginia) examined the thermodynamics of folding of biopolymers, with particular reference to the thermal cooperative transition to a partially unfolded state on an effective 2-state basis, and to the associated large change in heat capacity ($\triangle C_p$). Large differences in heat capacity between conformational states of biopolymers is now well established, and can be attributed in part to large changes in hydrophobic bonding, and in part to changes in solvent (water) structure due to the rupture of internal hydrogen bonds by partial unfolding, and the formation of new hydrogen bonds between exposed side chains and solvent molecules.

S. Lifson (Weizmann Institute, Rehovot) appealed, with both eloquence and wit, for an increase in the precision of calculation of molecular properties from crystal structure data, arguing that results "in the ball park" were no longer of interest. Conversely, the more precisely that calculations agree with experiment the more interesting the remaining discrepancies become in pointing the way to modification of theoretical parameters. After demonstrating the success of the consistent force field (CFF) method for calculating the properties of the alkanes, Lifson reported a study of the hydrogen bond, starting from crystallographic data on several amides to find the best force field. In the final result charge transfer seems to be unimportant and a 12-6-1 potential, which combines the Lennard-Jones 6-12 potential with partial charges attributed to the participating atoms while keeping the bond electroneutral, properly represents the hydrogen bond. There is a reduction in the effective van der Waals radius of the amide hydrogen, due to shifting of the electron cloud and formation of a large partial positive charge. This allows close approach of the >NH and O=C< groups to form a hydrogen bond of characteristic length, and the resulting associated electrostatic attraction is the main source of the bond energy. Lifson cheerfully conceded that this theoretical picture might have to be drastically modified to explain those features of hydrogen bonds revealed by infrared spectroscopy.

The extent to which the elucidation of hydrophobic bonding is dependent on a theory of water structure (still the subject of much argument) was emphasised by G. Némethy (University of Paris, Orsay) who pointed out that different agencies for changing hydrophobic bonding may alter the properties of proteins in aqueous solution in quite different ways.

B. Robson (University of Newcastle upon Tyne) discussed the application of information theory to estimate the extent to which sequence dictates secondary structure in the folding of a polypeptide chain. It seems that specific single residues can act as nucleation centres for secondary structure, and that the conformation of segments of the polypeptide chain are thus determined locally by the constituent residues. In the refolding process the locally ordered segments may represent metastable intermediates formed early in refolding and surviving in the stable completely folded conformation. Robson noted that Ramachandran conformational energy maps based on Lifson CFF functions were better than most, and also drew attention to map regions for the 4-residue reverse turn, which is now being recognised as an important element of secondary structure.

G. C. K. Roberts (National Institute for Medical Research, Mill Hill) described how NMR spectroscopy can be used to study protein unfolding, and referred to work on pancreatic ribonuclease (RNase). Subject to the difficulties of assigning NMR resonances to protons in individual residues, which is currently possible only for a small number of particular residues in the proteins studied in detail, it is possible in principle to follow the participation of individual residues in unfolding processes in reversible conditions. For RNase, the NMR studies indicate that the thermal transition at *p*H 5 proceeds cooperatively to a still partly ordered state, and that two of the four histidine C_2 proton resonances are affected. With denaturants such as guanidine hydrochloride, the NMR spectra at low denaturant concentration

indicate changes not revealed by optical methods. From resonance peak areas as a function of denaturant concentration, it seems that the order in which the histidine residues participate in the unfolding process is 12, 119, 48, 105. This order can be rationalised in terms of the known tertiary structure of RNase, and is therefore also relevant to the folding process.

The possible methods for revealing the existence of intermediate partially unfolded states were noted by R. H. Pain who pointed out that although some earlier equilibrium and kinetic studies on, for example, lysozyme unfolding in guanidine hydrochloride, indicate a 2-state process with first-order kinetics up to about 90% reaction, this situation is not general. The analysis of bimodal kinetics can reveal the presence of intermediate states, or of alternative states off the main folding-unfolding path. Pain reported his investigation of the pencillinase of *S. aureus*, a protein with no sulphydryl or disulphide groups, which was specifically selected for unfolding studies, and summarised the evidence for the existence of a highly expanded state, with the same α-helix content as the native protein, formed by a cooperative transition at low denaturant concentrations.

L. W. Nichol (Australian National University, Canberra) discussed ligand binding in associating protein systems, and showed how the form of the binding curve could be discussed in terms of regions of sigmoidality defined by the interaction parameters. He described how ultracentrifugal sedimentation equilibrium measurements can be used to evaluate these parameters. G. A. Gilbert (University of Birmingham) emphasised the central role of protein–protein interactions in the conformational control of protein function mediated by allostery, and pointed out that in the so-called non-equilibrium methods (for example, chromatography, electrophoresis, velocity centrifugation) the progress of the moving boundary reflects the equilibrium situation in the following plateau region, as well as the non-equilibrium situation within it.

The topical subject of membrane-bound proteins and protein–lipid interactions was discussed by C. Tanford (Duke University). Experimental data on protein–detergent associations (much used as a contemporary model) were described. The behaviour of cytochrome *b5* and a phage protein in detergent systems as consistent with the idea that membrane proteins possess distinct regions around which true micellar structures can organise. The discussion included a brisk exchange on the problems of measuring protein molecular weights by ultracentrifugation in the presence of detergents.

Proton NMR studies on histones were discussed by E. M. Bradbury (Portsmouth Polytechnic). With increasing ionic strength structure is induced through interchain interactions between regions of apolar residues, and the basic segments interact with DNA, leading to the formation of chromosome superstructure. The lysine-rich F1 histone, however, seems to be involved specifically in salt-induced contraction of chromatin gel, and in chromosome condensation through a phosphorylation process.

The programme included two parallel sessions of shorter papers on various aspects of protein unfolding and folding processes, ribosome reconstitution, RNA-protein complexes, and mucoprotein. Noteworthy was the study by Creighton, Dyckes and Sheppard (MRC Laboratory of Molecular Biology, Cambridge) on the refolding of reduced pancreatic trypsin inhibitor, in which the different species existing at the 1-disulphide bond stage were detected and characterised. The refolding of this protein proceeds with eventual complete recovery of native structure, and the pathway for refolding indicated by this work is consistent with the view that folding is directed by segments which have acquired the correct secondary structure.

Chlorophyll and primary productivity

from our Plant Ecology Correspondent

SINCE chlorophyll is essential for photosynthetic energy conversion, it is not unreasonable to suppose that it might provide a rough estimate of the potential gross primary productivity of an ecosystem. Early in this century the work of German plant physiologists suggested a close relationship between chlorophyll and photosynthetic rate. Later it became apparent that the chlorophyll density of vegetation expressed as g m^{-2} of ground area was remarkably similar in a variety of ecosystems and this led Odum (*Fundamentals of Ecology*, Saunders, 1959) to propose that there is a community homeostasis in which chlorophyll levels are maximised within the limiting physical constraints of the environment, leading to similar chlorophyll densities in most ecosystems.

Such a tenuous hope was shattered by Bray (*Can. J. Bot.*, **38**, 313; 1960) who concluded that chlorophyll densities in a wide variety of vegetation types might vary by as much as twenty times in natural ecosystems. He found that chlorophyll densities were higher in climax ecosystems than in seral ones and were greatest in highly stratified systems such as forests. These conclusions were largely confirmed by Ovington and Lawrence (*Ecology*, **48**, 515; 1967) who made detailed studies of four contrasting ecosystems—a prairie grassland, a savanna, an oakwood and a maize field.

Although Odum's simple homeostasis proposal was no longer tenable, there remained the possibility that chlorophyll might provide an index of gross primary productivity. Ovington and Lawrence's data in no way contradicted such a proposal. The underlying presupposition, however, is that all of the chlorophyll present must be active in photosynthesis whenever light levels permit; physiologists have always regarded this as extremely unlikely.

One rather startling observation which Ovington and Lawrence made was that a large proportion of the total chlorophyll content of their oak woodland was contained in the branches of the trees. In the month of August the trees themselves contained 29×10^3 g ha^{-1} chlorophyll, of which 12×10^3 g ha^{-1} (41%) was contained in the older branches. The bulk of this branch chlorophyll remained after leaf fall in September/October. Immediately the question must be raised as to whether this large reserve of chlorophyll is active and, perhaps even more important, whether it could result in winter photosynthesis in these deciduous trees.

Although only relatively simple experiments were required to settle this question, they have been conducted only very recently. Much is known about the winter photosynthesis of evergreens (see, for example, Kozlowski and Keller, *Bot. Rev.*, **32**, 293; 1966) but very little work has been done on deciduous trees. Keller (*Photosynthetica*, **7**, 320; 1973) has now examined rates of photosynthesis and respiration in the bark of ash (*Fraxinus americana*), aspen (*Populus tremula*) and larch (*Larix decidua*) during the winter. In his experiments plants were taken from their growing sites where they had been exposed to normal winter temperatures, they were kept at 16°C for 16-20 h and their carbon dioxide exchange rates were then measured by infrared gas analysis at 40, 10 and 0 klx respectively. In all species at all light intensities the carbon dioxide emission exceeded absorption; in other words, respiration exceeded photosynthesis. Thus, despite the presence of abundant chlorophyll, these species are likely to be experiencing a negative carbon balance through the winter months.

These experiments should serve as a salutary warning to production ecologists of the dangers inherent in the use of chlorophyll level as a productivity index, despite the general correlation between chlorophyll density and the gross primary productivity of ecosystems.

DNA-mediated genetic correction of thiamineless *Arabidopsis thaliana*

L. Ledoux* & R. Huart

Section de Biochimie cellulaire, Radiobiologie, Centre d'Etude de l'Energie Nucléaire, Mol, Belgium

M. Jacobs

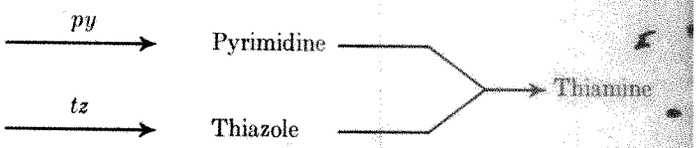
Laboratorium voor Plantengenetica, Vrije Universiteit Brussel, Belgium

Thiamineless mutants of Arabidopsis *were corrected by treating the seeds with DNA preparations from various bacteria. Possible mechanisms for this are discussed.*

TRANSFORMATION of prokaryotes by addition of exogenous genetic information has been possible since the classical experiments of Avery *et al.*[1] and since the demonstration that bacteria can take up and integrate DNA into their genome by genetic recombination.

Until recently, such 'cell manipulation' with higher organisms seemed almost impossible, presumably because of the inadequate means available for critical studies. The necessary biochemical background had to be obtained: good methods to prepare nucleic acids and to recognise them in a population of similar molecules had to be developed. The scarcity of mutants with defined biochemical lesions precluded (and still limits) genetic experimentation[2,3].

Nevertheless, DNA-mediated corrections in higher organisms were reported: with mammalian cells in tissue culture[4–12], with *Ephestia*[13] and with *Drosophila*[14,15], with *Petunia*[16–19] and with *Arabidopsis thaliana*[20–25]. Finally, phage-mediated corrections were reported with animal cells[11], with haploid tomato and *Arabidopsis* calluses[26–28] and with sycamore cells[29].



Extensive use of the CsCl gradient technique has led to the unexpected results that foreign DNA can be translocated to large distances across cell membranes[30,31] and seems to survive several mitotic cycles in different animal or plant systems[2,30,32]. In *A. thaliana*, it seems to survive at least one round of meiotic division[23,25,33]. More surprisingly, it seemed that the foreign DNA became covalently linked to the recipient DNA[21,23,25,30] as double-stranded material (a phenomenon similar to the incorporation of the λ DNA in the *E. coli* genome).

As already indicated in preliminary reports[20,25], correction of nutritional mutants of *A. thaliana* by exogenous DNA was attempted. We present here an overall picture of the results so obtained. More extensive genetic data will be presented elsewhere.

Nutritional mutants of *Arabidopsis thaliana*

Described auxotrophs are rare in *A. thaliana*, with the exception of those requiring thiamine[34]. They can be obtained by X rays or chemical mutagens. They are also conditional obligate auxotrophs with a strict phenotype, whilst other auxotrophs exhibit bradytrophy.

Mutants at one locus (*py*) control the synthesis of the pyrimidine moiety of thiamine[34,35], locus *tz* controls the synthesis of the thiazole half of the vitamin and two other genes are concerned with some intermediate steps between these two precursors and thiamine[34]. These mutants can be used for strictly genetic studies such as allelic complementation or recombination or reverse mutation because of the built-in selective mechanisms[34]. The mutability of the *py* locus is apparently the highest[34,35] and is close to 2×10^{-4}. The frequency of spontaneous reversion has been estimated to be lower than 5×10^{-6}.

Treatment with ethyl methanesulphonate produced apparent reversions at the *py* locus, at a frequency of about 4×10^{-5}. These revertants were nonhomozygous and segregated in the following generations. In test crosses, they also yielded heterozygotes and lethal mutants in approximately equal frequencies[36]. No homozygous wild types were thus obtained by back mutation.

The monogenic conditional lethal mutants used here are normally propagated in the presence of thiamine. When sown on mineral medium, the seeds germinate normally and develop their cotyledons which appear normal green. The first leaves progressively bleach out completely and the plant soon dies. Thiamine (10^{-6} M–10^{-5} M) promotes a normal growth of all these mutants.

Mutants used in this study were the following: *thi*51 from Rédei, *thi*V447 and *py*V131 from Feenstra, and *py*431 and *tz*432 from Jacobs. They bear the side markers indicated in Table 1; the only wild-type *Arabidopsis* used in the laboratory was the Wilna *g*1.

Treatment of seeds

Seeds were disinfected with a 95% ethanol and 3% H_2O_2 mixture (1:1) or with a 5% calcium hypochlorite solution[34]. The seeds were treated for 5–8 min and rinsed with a few changes of sterile distilled water. About 50 seeds were then immediately placed in a well of a spot plate and immersed in 25 μl of a DNA solution (see below) or of 0.01 M NaCl. Spot plates were placed in Petri dishes over wet sterile filter paper to limit evaporation of the solvent. During the three following days, 25 μl of the DNA solution were added to the seeds to keep them moistened. Petri dishes were kept at 24° C under continuous illumination for 4 d. Both DNA and NaCl treated seeds germinated during the incubation period. After incubation seedlings were laid out (a) in tall Petri dishes containing perlite moistened with the mineral nutrient solution of Jacobs[37] or (b) in numbered test tubes containing 5 ml 0.78% agar dissolved in the mineral nutrient solution

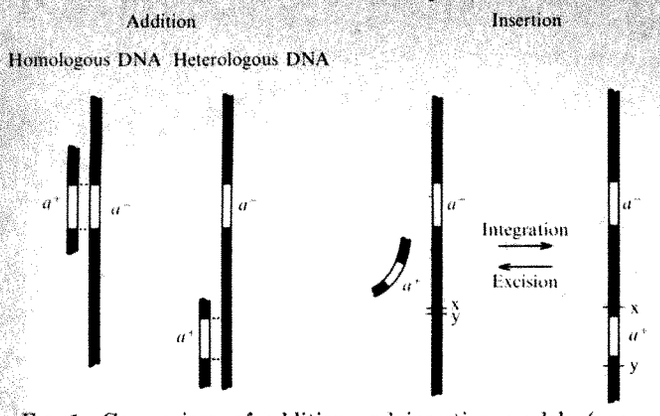

FIG. 1 Comparison of addition and insertion models (one of two homologous chromosomes is shown). In *Drosophila* transformed by homologous DNA Fox's exosome model implies a close association of the foreign gene with its homologous chromosome locus. This exosome is not integrated but replicates in step with the chromosome and can be lost or transmitted with it at the time of cell division. Either the exosomal gene or the chromosomal one is transcribed, leading to phenotypic mosaicism. When heterologous DNA is used for correction, as in our case, the necessity of a close association with the mutated site is less mandatory and the heterologous exosome could become associated to another region, where the actual base sequence is in favour of such an association. Here too, the exosome could replicate in step with the chromosome and be lost or transmitted with it at the time of cell division. The probability of a loss would however be high due to the imperfect homology. In the insertion model, the foreign gene is integrated in the recipient DNA, like episomal DNA, through the homology of a few base pairs. Once integrated, it would be hard to lose it, except on pairing with a chromosome homologous for the rest of the structure but lacking the inserted foreign piece. Although gene conversion could interfere at that step, chromosome aberration is an obvious alternative, possibly leading to the loss of the foreign gene.

of Miksche and Brown[38]. The tubes were placed in wooden racks, kept under continuous illumination (6,000 lux) at 24° C and examined each second day.

All mutant seedlings on mineral medium died within 15–20 d; they showed chlorophyll deficiency in the cotyledons and in the rosette leaves. Corrected plants grew slowly, with a more or less normal green colour. About one-third produced fertile siliques (see below). These siliques were collected and kept separately in cellophane bags. The thiamine concentration necessary to provide complete growth when seeds were soaked in it for 3 d, then washed and allowed to develop in the absence of thiamine, was found to be about 10^{-3} M.

DNA preparations

DNA preparations were obtained from frozen or fresh bacteria (or from isolated and CsCl-purified bacteriophages) by the technique of Marmur[39] or by CsCl gradient preparative ultracentrifugation, after treatment with pronase and RNase[40]. The DNA was precipitated with 2 volumes of ethanol, kept in 70% ethanol, and dissolved in sterile 0.01 M NaCl just before use. The concentration used was about 0.5–1.0 mg ml^{-1}. We successively tried and rejected the use of chloroform or phenol for deproteinisation: both are toxic to the plant. They may also selectively remove the protein or membrane bound DNA molecules from the bulk of the DNA preparation.

Our study of the biochemical fate of labelled DNA in various systems led us to recognise that the DNA has to be freshly prepared, of high molecular weight ($> 10^7$ daltons), very clean and intact. When single-strand breaks in a DNA preparation could be detected from the depolymerising effects of alkali[40], the preparation was discarded. Finally, the DNA had to be given during the first 24 h of imbibition of the seeds; otherwise it was not integrated into the recipient material (unpublished data).

In general, we used small numbers of seeds per batch of DNA and preferred to repeat the treatment with freshly prepared batches. Perhaps because of fragmentation of the DNA molecules during their isolation and purification, some batches of a given DNA species were ineffective with the mutant plants tested, whereas others were quite effective. Yet these DNAs were undistinguishable by the physiochemical methods used. Even if it is tempting to blame the DNA itself, it is of course difficult to eliminate uncontrolled parameters related to plant growth as the source of these discrepancies.

DNA was prepared from the following strains: *Escherichia coli* K12, wild type; *Agrobacterium tumefaciens* B6, obtained from Dr A. Kurkdjian; *Bacillus subtilis*, 168 T^-; *Micrococcus lysodeikticus*, ATCC 4698; *Streptomyces coelicolor* AS/2 obtained from Dr H. Hopwood; *E. coli* P678 (*thia*A). Phage T7 (with normal bases) and phage 2C (with hydroxymethyl uracil replacing thymine) were also used. They were isolated and purified following the technique of May *et al.*[41]

Correction in DNA-treated populations

When seeds of the different mutant types were treated with different bacterial DNAs, corrections could be obtained with a relatively high frequency (10^{-2} to 10^{-4}) comparable with that observed with bacterial transformation. Table 1 shows an overall picture of the data gathered during the last 3 yr with a total of 27 different batches of DNA tested with five different mutants. These data include DNA extracted from wild-type bacteria, from bacteria with a thiamine deficiency (corresponding to the thiazole pathway) and from phages containing normal (T7) or abnormal (2c) bases.

Further controls were obtained by treating mutant seeds with 0.01 M NaCl, the solvent used for the DNA assays. After DNA treatment, a few mutant seedlings, which normally died within 15–20 d of sowing, displayed better growth, formed small rosettes and eventually flowered. Only a few of them were fertile, however. Table 1 takes into account only the restored plants which produced seeds, thus allowing a study of their progeny. Table 1 also indicates, for each case, the number of germinating seeds and the total number of seeds used. Contamination by wild-type seeds is highly improbable as strict precautions were taken in treating and growing the plants. Furthermore, most of the mutants used bear additional markers which make them easily recognisable from the only wild-type strain used in the laboratory. These results indicate that the percentage of correction obtained with the group of DNAs from wild-type bacteria is similar for all mutants: 0.7%, 0.85% and 0.49% respectively for thiamine, thiazole, and pyrimidine-requiring mutants. On the other hand, the percentages of correction obtained for five mutants seem to vary with the source of DNA, *E. coli* being at the moment the most effective (0.89%) and *S. coelicolor* the less effective source of DNA (0.19%). Negative results were obtained with DNA from phage T7 or phage 2C. DNA from *E. coli thia* did not correct thiazole mutants but, as expected did correct pyrimidine ones. It should also be noted that in all cases, the DNA-treated plants, growing in the absence of thiamine showed a delay in growth and development, as compared with the wild type or to mutants supplemented with thiamine (5×10^{-5} M).

Progeny obtained by selfing corrected types

Progenies of various corrected types obtained after DNA treatment were sown on perlite soaked with mineral medium or on soil and observed during the entire growth of the plant. The number of F1 plants tested varied as a function of the number of seeds present in the fruits of the corrected plant growing on a thiamineless medium. In a very few cases, thiamine was provided at the flowering stage to increase vigour and thus seed production. F2 and F3 progenies in-

cluded at least fifty plants for each experiment. The majority of the corrected plants were studied up to three successive generations and fresh and dry weights for 5 corrected mutants were determined.

The most striking result of this study concerns the lack of segregation on selfing in the progenies of the various corrected types. All F1 to F3 plants originating from each corrected plant look phenotypically alike and grow reasonably well on mineral medium. This was observed also in one case where the selfing was pursued up to the seventh generation. They show, however, in most but not all cases, a variegated pattern of chlorophyll pigmentation with light discolouration at the base of the leaf and along the main vein. In practically all cases, the average fresh weight (and particularly the average dry weight) of the corrected types grown on mineral medium, were lower than those of plants from the same progeny, supplemented with 10^{-4} M thiamine (37 to 92%). Each of these types thus display sensitivity to the addition of thiamine. Other experiments showed that the corrected 'pyrimidine' or 'thiazole' mutants specifically responded to the addition of pyrimidine or thiazole and showed an improved growth. On the other hand, and contrary to the situation for wild-type control plants, the progeny of some of the corrected plants exhibit thermosensitivity; at 16° C they showed signs of thiamine deficiency, which disappeared at a higher temperature.

In selfing experiments, the corrected plants behaved as homozygotes breeding true, in contrast to what is found with mutagen-induced revertants. This is also in contrast to what is expected in the case of a suppressor mutation introduced into a homozygous diploid. Indeed, in the seed, the germline is represented by two diploid cells[42,43]. These cells, at least, should contain the thiamine information to explain the lack of segregation after selfing. In F1 the ratio of mutants: wild types should vary from 1:3 to 1:7. The fact that correction results in a homozygous corrected plant suggests that there has been continuous selection for the corrected germ cells and, presumably a meiotic drive at the time of meiosis favouring those gametes which harbour the thiamine information. Indeed, when selection pressure is avoided by giving thiamine supplementation to plants treated with DNA which show signs of abortive flowering, a high percentage of lethal mutants is observed in the F1 progeny.

Offspring of out-crosses

We have analysed, in parallel, the offspring of crosses made between corrected plants and either the wild or the original mutant type (back or test crosses). Table 2 shows the results obtained in the case of tz^c a homozygous 'thiazole' mutant corrected by a treatment with *B. subtilis* DNA. (Similar data were and are being gathered for other corrected types such as py^c, th^c or tz^c corrected with other DNA. They will be described elsewhere together with the results of crosses between mutants corrected with different DNA). The phenotypes presented by progenies of successive self fertilisation were analysed.

The first generation of the outcrosses (x) does not segregate. The results of the test cross ($tz^c \times tz^-$) implies that the correction is dominant and that the corrected plants behave as true homozygotes. Reciprocal crosses between corrected mutants and lethal mutants indicated that the correction can be transmitted through the male as well as through the female and therefore does not seem to correspond to a maternal cytoplasmic factor.

Leaky mutants

Segregation is observed in the offspring of the corrected plants outcrossed to the wild type (xF1 → xF2). Lethal mutant types are recovered (although in low frequencies) together with plants exhibiting a new phenotype called here 'leaky mutant'. This is characterised by a weaker pigmentation, white patches of discolouration on the leaves, sometimes white sectors on the stem and relatively poor growth and fertility, in contrast with the normal looking plants of the same progeny. A whole range of these phenotypes, intermediate between the normal green plants, and the lethal chlorophyll deficient plants were classified under the name 'leaky mutant'. These mutants are obtained in crosses between the corrected type and the wild type, as well as in crosses between the corrected type and the lethal mutant (in the latter case, a high frequency of lethal mutant being obtained). The leaky types keep their sensitivity to supplementation with thiamine, thiazole or pyrimidine respectively. This indicates that the correction has been added to the mutation and has not been substituted by it. Correction being dominant, the recessive mutation is not expressed unless the correction is masked or lost, for instance by crossing with an uncorrected plant.

The leaky mutants are found at equal frequencies in the XF1 offsprings from $tz^c \times tz^+$ (9.2%) and $tz^c \times tz^-$ (6.1%). Their offspring includes high frequencies of leaky and lethal types and also normal looking plants. This normal phenotype can be recovered at frequencies (21.7% and 24.7%) suggesting that the 'leaky mutants' behave as heterozygotes. They should however, also segregate into mutant types with similar frequencies. The correspondingly lower values obtained for the lethal mutants and the reproducibility of the phenotype distributions could be acounted for by various mechanisms.

We expected that this study would help to correlate genetic and biochemical data. This was in fact the main reason why bacterial DNA was used in the biological studies. We have not used homologous *Arabidopsis* DNA because it

is difficult to prepare from this material the clean, intact DNA of high molecular weight which we consider a prerequisite for efficient uptake and integration. On the other hand, although we wanted to use specialised transducing phages to introduce selected genes only, we were not in a position to do so, because of the lack of phages carrying thiamine information. (The amount of DNA which can be taken up by a cell is limited as are the size of the populations to handle. It therefore seems reasonable to try to increase the dosage of the interesting gene in the DNA preparation used. This can be achieved by using DNA from bacteria, transducing phages or episomes.) This kind of difficulty has recently been overcome by using DNA from thiamineless bacteria (ineffective as such for correction) harbouring a F′ factor bearing the thiamine information (KLF10). These results will be published elsewhere. To what type of genetic model do these results lead?

Transformation models

Different models have been discussed by Fox *et al.*[15] to explain their results showing genetic transformation in *Drosophila* with homologous DNA. They argue in favour of the exosome model, also considered by Hess to interpret *Petunia* transformation. The exosome model (Fig. 1 of ref. 22) is the only one which does not require an integration of the exogenous information into the linear structure of the chromosome. Such an integration is rejected by Fox because of the absence of whole-body transformants among the transformed *Drosophila* and to the instability of the correction. In the *Arabidopsis* system the nonautonomous type of biochemical lesions arising from the possible diffusion of thiamine makes it difficult to ascertain the presumably mosaic nature of the corrected type. Its progeny is, however, easier to analyse. It therefore seems that the corrected plants do behave as homozygotes as they do not segregate in their offspring (they do not segregate 1:1 in test crosses). As the correction is stable in subsequent offspring, it must correspond to a surprisingly stable form of exosome.

The effect of the exogenous DNA seems to be associated with the gene concerned (thiamine, thiazole or pyrimidine loci). This leads to the concept of an association of the bacterial information with the *Arabidopsis* genome. Such a close association is also indicated by the absence of significant differences between progenies of reciprocal crosses implying corrected types; 100% normal plants are obtained upon crossing corrected either male or female to the mutant type. The thiamine mutation remains in the genome of the corrected type; by crossing the corrected plants with the wild type, a resurgence of the original mutant type does occur in F2 although at very low frequencies. In fact, the passage through meiosis for the plants arising from a cross with one of the corrected types seems to increase the instability of the exogenous information. This seems to be the consequence of the appearance of the 'leaky mutant' phenotype (which could eventually be considered as functional mosaics).

The regularity in the transmission of the genetic information as well as the survival of the mutated site in the corrected plant could be explained if we assume that the necessary amount of information has been added to the genome (and not substituted for the mutant gene) and can be removed by crossing the plant with the wild type or with the mutant, but not on selfing. Perhaps difficulties in chromosome pairing, because the correction is present in only one of the two homologous chromosomes forming the bivalent, could be responsible for removing this correction. Such a picture fits well with the 'episomal DNA' type of interpretation (Fig. 1 of ref. 22) emerging from the biochemical analysis. This model also allows an explanation for the variability in the functioning of the bacterial thiamine gene in the recipient plant, possibly related to its relative position. These differences in the phenotypic expression of the thiamine locus do not seem to result from a lack of integration but from a change in the gene environment that is able to influence its genetic transcription and therefore its expressivity.

We thank J. Swinnen-Vranckx and L. De Mol for technical help and Drs M. Mergeay, Glansdorff, P. Charles and P. Lurquin for discussions. M. Mergeay and R. Martin purified and cultured most of the bacteria used; P. Charles and J. Remy prepared most of the purified DNA and ran the necessary physicochemical controls of quality. We thank Professor G. Rédei for revising the manuscript and for advice and criticism. We thank the Fonds National de la Recherche Fondamentale Collective and the Ministère de l'Education Nationale for financial help.

Perturbations of Pioneer 6 telemetry signal during solar occultation

ATTENTION has been drawn recently to unexplained perturbations in the telemetry signal of Pioneer 6 (2,300 MHz) during solar occultation. The results[1] shown in Fig. 1 present the following odd features:

(1) An anomalous redshift is added to a normal linear redshift due to the spacecraft oscillator. This residual redshift which is symmetrical with respect to the centre of the Sun is of the order of $z = 5.18^{-8}$ at four solar radii.

(2) The bandwidth increases sharply when the telemetry signal grazes the Sun.

(3) There are some extremely sharp pulses in the bandwidth. In Fig. 2 we show that these pulses are clearly associated with a sharp increase of the redshift and correspond to solar flares.

The existence of the redshift is particularly puzzling because it cannot be attributed to gravitational effects nor to the usual Doppler effect.

Various explanations of those phenomena have been attempted:

Photon-photon interaction: P. Merat and colleagues[8] (unpublished work) have presented an explanation based upon previous work by Pecker, Roberts and Vigier[2,28]. Assuming an hypothetical photon-photon interaction, they supposed that each photon passing through a photon bath loses energy according to the semi-empirical law:

$$z = -\delta\nu/\nu = C \int U(s)\, ds$$

where $U(s)$ represents the background photon density, s the distance travelled and C a constant whose value lies around 10^{-30} cm^2 erg^{-1}. Their hypothesis gives a good account of the redshift. But the width of the signal remains unexplained, as does the correlation with solar flares; indeed the photon density $U(s)$ remains constant during the flare. And the

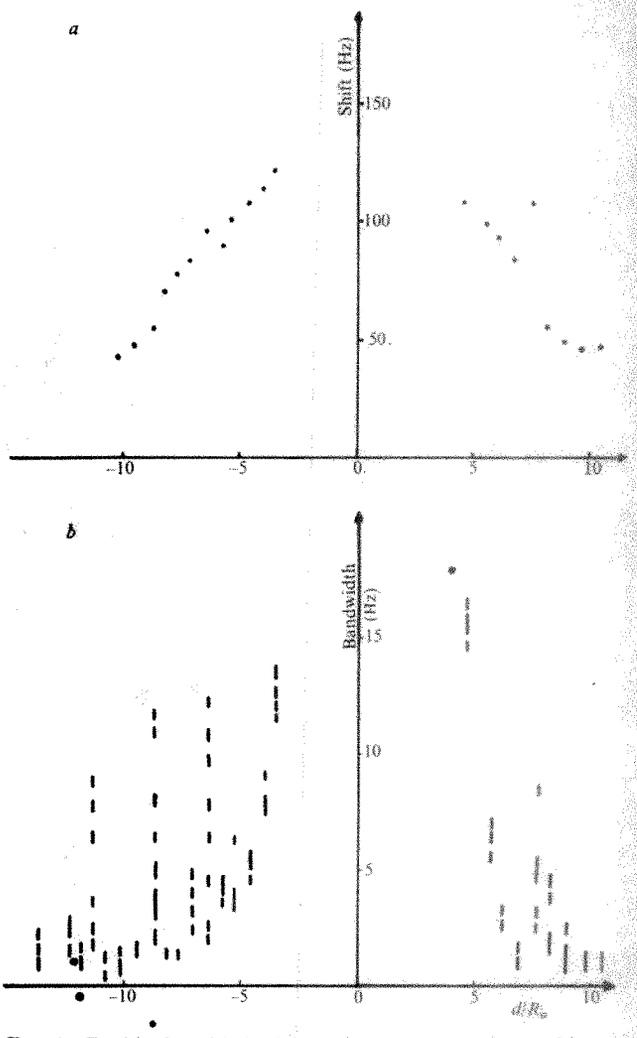

FIG. 1 Residual redshift (*a*) and bandwidth (*b*) in Hz as functions of the minimum distance of Pioneer 6 telemetry signal to the centre of the Sun.

12375

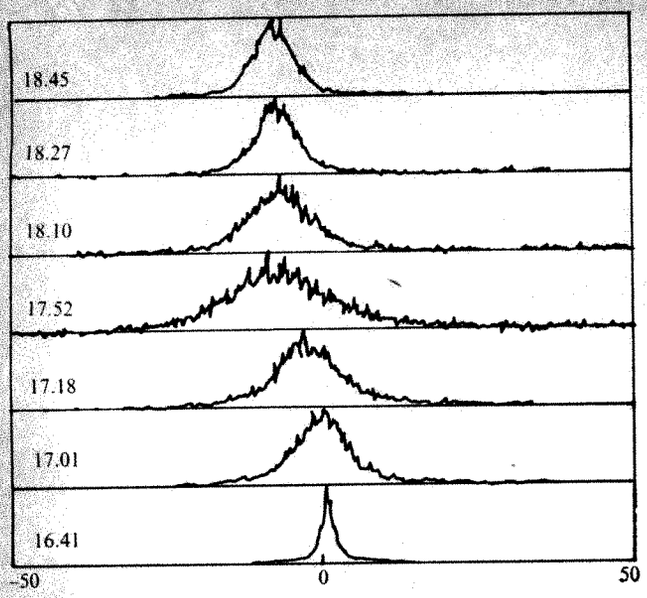

FIG. 2 This sample spectrogram taken on November 8, 1968, shows the effects of a solar event and demonstrates the association between the broadening of the line (12 Hz · h^{-1}), the anomalous redshift (4 Hz h^{-1}) and the solar flares.

Theoretical foundation of their formula is, in our opinion, unclear. We have therefore considered more 'classical' explanations.

Doppler-type effect: The optical index n varies when the signal passes through the solar corona. But it is easy to see that this effect is too small (of the order of 2.5×10^{-9}) and asymmetrical with respect to the Sun.

Induced scattering: It is well known that induced scattering gives rise to a redshift of intense electromagnetic radiation if the scatterers have a decreasing energy spectrum. This is true for ions and electrons. But calculations including an energetic tail in the distribution function of the electrons indicate that the effect is much too small. Scattering which might change the nature of the waves, in particular Langmuir into electromagnetic waves, is inefficient at this frequency.

Non-linear wave interactions: The combination and decay of waves or scattering of waves by waves must be considered. A plasma can support electromagnetic waves, space-charge waves and low frequency waves of the acoustic type. But interaction of electromagnetic waves with high frequency (Langmuir) waves leads to the build-up of a system of satellite lines, at a distance from the central lines equal to the plasma frequency ω_e that is much larger than the frequency window in Goldstein's experiment. Similarly, scattering of these waves would introduce both a large angular scattering and a frequency broadening of the order of the plasma frequency.

Therefore, low frequency waves are the only ones that may give rise to the perturbations.

We emphasize that if such processes are responsible for the perturbations of the signal, it is simple to explain why these perturbations are correlated with solar flares, which are known to generate strong electronic perturbations in the solar corona. Low frequency waves in the solar corona can be either ion-sound waves or magneto-sound waves depending on the magnetic field.

Evidence for the existence of ion-sound waves in the solar corona are of three types: (1), Gordon[3] explained strong radar backscatter from the Sun using them; (2), scintillations of radio sources allow us to study the density fluctuation and therefore the level of turbulence $W_{turb}/W_{th.e}$ in the corona, at least at high altitudes; (3), broadening of sources of solar origin (such as Type I and Type III bursts[4]) indicates that density fluctuations are certainly present.

From all these data we estimate that at four solar radii the level of turbulence is of the order of a few per cent while the frequency ω_s of the ion-sound waves could be of the order of 0.1 Hz.

Our calculations have shown that induced processes are negligible and that the decay process (e.m. wave → e.m. wave + ion-sound wave[6]) gives essentially a broadening of the line:

$$\Delta\sigma^2 = \frac{1}{512\pi} \frac{\omega_e^4 \omega_s}{\omega^2} \frac{L}{c} \frac{c_s}{c} \frac{W_{turb}}{W_{th.e}}$$

where $W_{turb}/W_{th.e}$ is the level of turbulence and L the interaction length between the solar plasma and the telemetry signal. At four solar radii, ω_e and c_s/c have to be taken respectively as 10^7 Hz and 3×10^{-4}, leading to a broadening of the line of the order of 10 Hz as observed. Further, the scattering process (e.m. wave + ion-sound wave → e.m. wave + ion-sound wave[7]) could very well produce a redshift. Detailed calculations of this effect will be presented elsewhere.

Speeding up astronomical photography

VARIOUS methods have been used for increasing the sensitivity of photographic emulsions prior to exposure in the telescope. For example, washing red sensitive (panchromatic) emulsions in ammonia or water, and latterly baking blue sensitive (orthochromatic) emulsions at 50° C have given reductions in the exposure times required to reach a given density, although at the cost of greater intrinsic fog and non-uniformities, and poorer photometric properties. More recently, placing the photographic plates in vacuum for several hours, with or without simultaneous baking, has come into common use for some emulsions, and this has been followed by baking in a dry nitrogen atmosphere (see ref. 1 and references therein).

The object of baking or vacuum treatment is to remove from the emulsion water vapour and oxygen, which act as desensitising agents. Both techniques depend on the principle of excess partial pressures to drive out the unwanted gas or vapour, in the first by increasing the partial pressures in the emulsion and in the second by reducing them in the ambient atmosphere. Both produce undesirable side effects, the first an increase of intrinsic fog, often non-uniform, the second the removal of all gases and a shrinkage and hardening of the emulsion.

It seemed to us that the objective could be achieved on the basis of excess partial pressures but without introducing undesirable side effects, by prolonged soaking of photographic plates in oxygen-free dry nitrogen of high purity, at room temperature and pressure. So we carried out experiments in the laboratory at Edinburgh in mid-1972, photographic plates being stored in a gas tight tank which

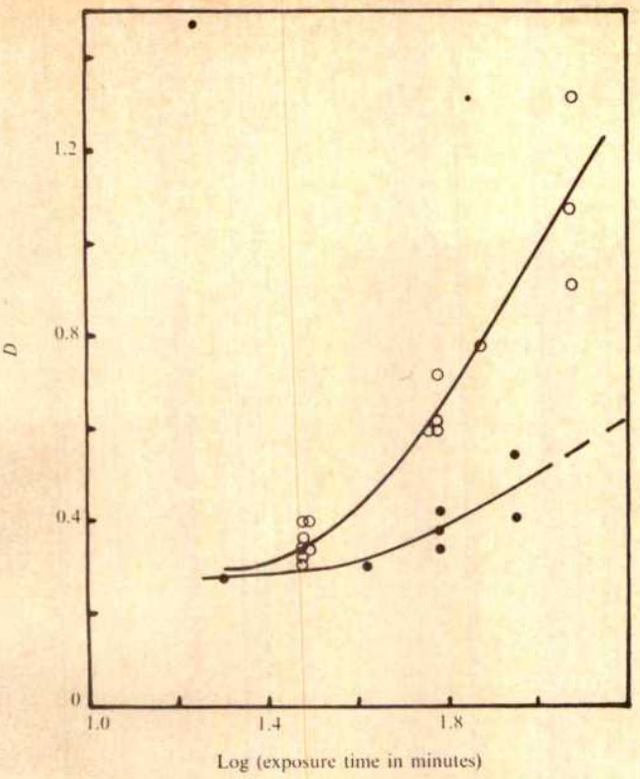

FIG. 1 Photographic diffuse density against logarithm of exposure time in minutes. Open circles, nitrogen sensitised IIIaJ emulsion; filled circles, unsensitised.

was flushed with high purity nitrogen for several minutes each day. These experiments showed that, in the case of the Kodak IIIaJ emulsion, nitrogen soaking for a month was necessary and gave reductions by factors of between two and five in the exposure times needed to reach moderate density—a similar result to that obtained by vacuum baking but without the undesired increase in intrinsic fog.

Prolongation of the soaking gave no further gain but no deleterious effects resulted. Delaying exposure of the plate for 24 h after removal from the nitrogen showed no significant fall in the sensitivity that had been gained—a not unexpected improvement over the alternative baking and vacuum techniques.

These preliminary results were communicated privately to astronomers in Britain, at the European Southern Observatory and at Palomar, and to Eastman Kodak.

The nitrogen soaking technique has been in routine use with the *f*2.5 UK 48-inch Schmidt Telescope at Sliding Spring, Australia since the telescope was commissioned in July/August 1973. Here we report on the efficacy of the technique in operating conditions; this is important because it is well known that the photometric properties of photographic emulsions generally depend on the temperature and humidity prevailing during exposure in the telescope. The results refer to Eastman Kodak IIIaJ plates (batch 2C3) since this emulsion type is to be used for the Science Research Council's southern sky survey.

Figure 1 shows the densities reached with given exposure times in the telescope for 15 sensitised and 7 unsensitised plates. The sky brightness during the exposures was $B = 22.25 \pm 0.1$ mag (arc s)$^{-2}$, measured by a photoelectric photometer. The densities measured by a Macbeth densitometer are close to ASA diffuse values.

There were considerable reductions in the exposure times required to reach given densities, by a factor 2.5 at $D = 0.6$ and increasing with density (Fig. 1). Such a gain would, however, be spurious if the photometric properties of the emulsion had shown a corresponding deterioration. It is therefore important to compare the density noise before and after sensitising, and this is done through the factor

$$(D/\sigma_D)^2 \qquad (1)$$

where D is the density and σ_D is the r.m.s. density noise for the sampling aperture used, in this case 25μm × 35μm at the plate. The quantities were measured for nine sensitised and six unsensitised plates and show no significant difference between the two sets.

It is notable that any increase of intrinsic fog density due to the sensitising was ≤ 0.05.

A measure of efficiency sometimes used in the USA is

$$\text{overall efficiency} = \left(\frac{dD/dE}{\sigma_D}\right)^2 S \qquad (2)$$

where E denotes exposure and S the reciprocal exposure required to reach a specular density of 1.0 (probably close to $D = 0.6$ in this paper). The results produced here for the nitrogen soaking technique show a gain by a factor of about 20 in this measure at $D = 0.6$, about equal to the gain reported for baking in nitrogen.

Using sensitised IIIaJ plates, limiting magnitudes have been determined by photographing the star cluster Kron 3 which contains a photoelectronographic sequence to $B = 22.7$ by Walker[2]. These show that $B = 22.3$ is detected in 30 min, $B = 22.7$ is visible in 1 h, and easily visible in 2 h. A reproduction of a 2 h exposure is shown in Fig. 2. For comparison, an optimum 40 min exposure on IIaO emulsion reaches $B = 21.5$.

The nitrogen soaking technique has been tested on Kodak IIaO emulsion by B. A. Peterson and J. McKinlay at the

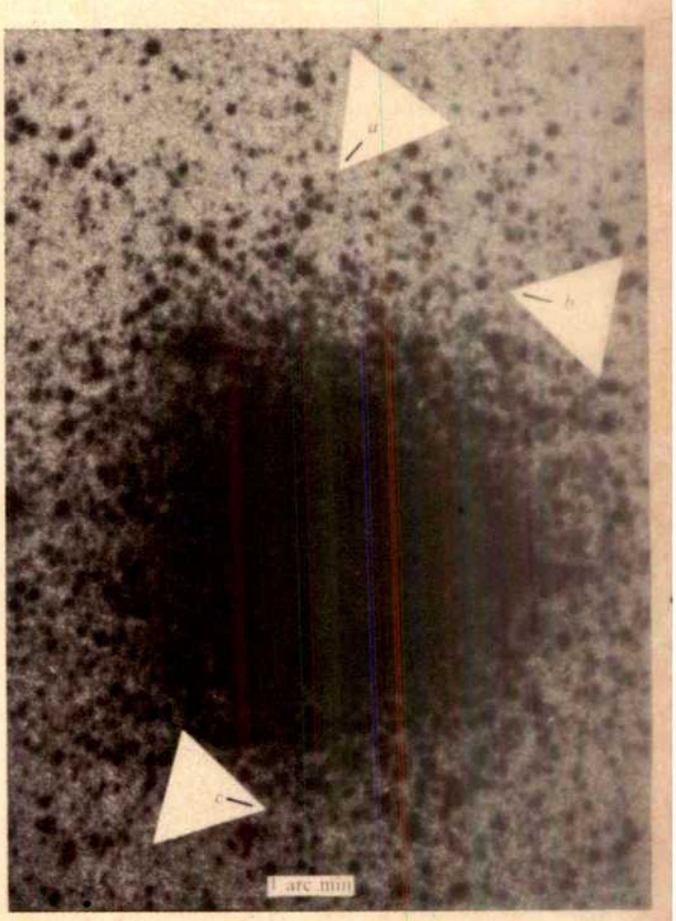

FIG. 2 Enlargement of the star cluster Kron 3 in the field of the Small Magellanic Cloud. Exposure 2 hours on nitrogen sensitised IIIaJ plate with the UK 48-inch Schmidt telescope. According to Walker's photoelectronographic measurements, the stars marked *a*, *b* and *c* are respectively of magnitudes $B = 22.7$, 22.3 and 21.7.

Mt Stromlo Observatory, and they report the same gain as for baking but without the undesirable increase in intrinsic fog.

The large gain in efficiency obtained by nitrogen soaking of the Kodak IIIaJ emulsion has led to it being used for the Science Research Council's southern sky survey which will consequently have a limiting magnitude $B = 23$. This is two magnitudes fainter than the Palomar survey of the northern sky which was caried out before this emulsion was developed.

Another emulsion with the high signal to noise characteristic of the Kodak IIIaJ is the Ilford R40. This panchromatic process emulsion was brought into use by one of us (V. C. R.) at the Royal Observatory Edinburgh in 1956 and has since been used regularly there and by the UK 48-inch Schmidt Telescope in Australia. It has good photometric characteristics, low noise and high uniformity. Nitrogen soaking does not affect its sensitivity. It is difficult to compare its performance with that of the IIIaJ because of the three times wider bandwidth of the R40 which has a peak sensitivity in the red, and because the telescope corrector plate is optimised for the blue waveband giving better images on the IIIaJ, but one hour exposures of the same field taken with sensitised IIIaJ and unsensitised R40 plates show that most objects occurring on either plate occur on the other.

Molecular hydrogen in X-ray astronomy

There is a serious discrepancy between determinations of the column density of interstellar matter in the direction of the Crab Nebula. Virtually every soft X-ray observation[1–5] with sufficient energy resolution to derive this column density yields a result substantially in excess of determinations based on 21-cm absorption[6–8]. The quality of the X-ray and radio data is now such that this disagreement must represent a genuine physical effect rather than an artefact of the data analysis.

It seems likely that this situation also applies to many or all galactic X-ray sources. The discrepancy is easily recognised in the Crab as it is a strong source with a well defined, nonvariable, power-law spectrum extending over many decades, but many other low latitude X-ray sources show a similar effect[9], as does a recent detailed study of the Tycho supernova remnant[10]. If the cause of this anomalous absorption is interstellar, it will affect all distance estimates of X-ray sources based on correlated 21-cm and soft X-ray observations.

So far there is no satisfactory explanation of this phenomenon. An increased abundance of heavy elements over that assumed in the X-ray photoelectric absorption cross section[11,12] has been considered[1,2,4], but the range of elements responsible for absorption in the 0.5–1.5 keV band is limited. Oxygen is eliminated[1] as the required absorption edge does not appear prominently in X-ray spectra. Helium cannot be solely responsible[4] since the required abundance increase would be hopelessly inconsistent with all other data. A substantial increase in the Brown and Gould[12] neon abundance coupled with a modest increase in helium could reconcile the data[4] but the latest estimates of the cosmic neon abundance[13–16] are at variance with this explanation.

Absorption due to interstellar grains with an extreme superabundance of carbon has also been examined[1]. An increase of the cosmic carbon abundance by an order of magnitude above currently accepted values is required. Carbon is one of the few reasonably well-determined heavy element abundances, so this seems unlikely.

I suggest that interstellar molecular hydrogen is responsible for a significant component of the necessary opacity. The predominance of molecular hydrogen in dark interstellar clouds is well understood theoretically and established observationally, and the very low abundance of H_2 in regions of negligible optical extinction also presents a consistent theoretical and observational picture. But the intermediate case of the fractional H_2 abundance in interstellar clouds of low to moderate optical extinction is not nearly so well studied or understood, and this is in fact the case appropriate to the Crab Nebula.

The optical extinction in the line of sight to the nebula has been determined by several methods[17–19] whose results agree quite well and centre on $A_V = 1.8$ mag. In this region of moderate extinction there have been detections of both hydroxyl[20] and formaldehyde (C. Heiles and T. Troland, personal communication; R. Davies, personal communication) in absorption against the Crab continuum source. These observations indicate two distinct molecular clouds which correspond well with neutral hydrogen features in both velocity and profile[6,7].

The chief problem is whether clouds of such moderate optical depth provide sufficient shielding from the interstellar ultraviolet radiation field so that any significant H_2 abundance may be expected in an equilibrium situation. I examine the feature[6] at 11 km s^{-1} and, since two molecular clouds are observed, assume that it provides about half the observed visible extinction, implying an optical depth of the cloud centre in visible light[21] of 0.4. It could be argued instead that the extinction increases in a completely linear fashion over the distance of 2 kpc, although the available data are against this possibility[18]. This, then, is an assumption of the model, although hardly an extreme one, and the X-ray data itself is evidence in its favour. Using the model parameters of ref. 6 and the shielding criterion of Hollenbach *et al.*[22], I find that H_2 can be formed for fractional molecular abundance of $f \gtrsim 0.8$. This is in fact close to the abundance that is observed by OAO for some stars with comparable visual extinction[23]. Under these assumptions, this cloud could contain $N(H_2) \geq 1.4 \times 10^{21}$ molecules cm^{-2}. Although interferometric studies[24] have shown small gradients in optical depth across the face of the radio source, the X-ray source is of much smaller spatial extent[25] and so all this material should be available to attenuate the X-ray spectrum.

This argument is conservative in that the direct observation of hydroxyl and formaldehyde is alone compelling evidence for the presence of a substantial amount of H_2. The nominal lifetime of these molecules in clouds of moderate optical depth is extremely short, which strongly implies a deficiency in the theoretical calculations of molecular formation or destruction rates, or both, in the sense that larger fractional abundances than predicted are invariably observed[7,26]. In particular, Herbst and Klemperer[27] have noted that all reactions which effectively produce formaldehyde require molecular hydrogen.

Can the inferred amount of H_2 provide the missing opacity? Unfortunately the photoelectric absorption cross-section of H_2 at soft X-ray energies is not well established, with theory[12] and experiment[28] in some disagreement between 0.1 and 10 keV, but calculations and experiments agree on the somewhat surprising result that the H_2 photoelectric cross section substantially exceeds twice the atomic cross section, apparently because of molecular bonding effects. There are no measurements at precisely the wavelengths of interest but Brown and Gould[12] estimate a cross section

of 180 b per molecule at 1 keV, giving the cloud under consideration an X-ray optical depth at this energy of $\tau \geq 0.25$. The amount of 'missing matter' generally derived by most experimenters[4,5] is of order 1×10^{21} atoms cm^{-2} or an optical depth $\tau = 0.3$. Thus the H_2 in this cloud alone may make a substantial contribution to the necessary opacity. Since both the theoretical and experimental values of the cross section increase more rapidly than that of the overall interstellar medium as one considers energies < 1 keV, even the smallest molecular hydrogen cross section recently suggested[28] will supply sufficient opacity at 0.5 keV to explain the entire discrepancy.

This sharp increase of the cross section at longer wavelengths also enables us to predict that the apparent opacity discrepancy should become worse for observations at softer energies. Thus a positive detection of the Crab source at 0.25 keV, which may be within present capabilities, would provide a test of this proposal. It may also be possible to observe the H_2 directly in absorption against bright stars with small angular displacements from the Crab using satellite-borne equipment. The colour excesses of the closest such stars, Zeta Tau and 114 Tau, indicate however that they are probably not behind the same cloud as the nebula itself.

There are several problems using correlated 21-cm and soft X-ray data to set distances to galactic X-ray sources[29]. Intrinsically variable and self-absorbed X-ray spectra, uncertain cross sections, abundances, spatial abundance gradients and interstellar medium excitation temperatures all contribute errors. If we now include the possible presence of non-negligible amounts of H_2 in the direction of many galactic X-ray sources it seems that, contrary to the conclusions of several previous investigations, such correlations may not be useful as accurate distance indicators.

The hypothesis presented here may have possible implications for observations of the soft component of the diffuse X-ray background. These molecular clouds of low-to-moderate optical depth are most easily recognised in absorption against a few strong radio sources but if they are present elsewhere in any significant number they could cause substantial small-scale granularity in the observed X-ray flux. This granularity will not necessarily be well correlated with 21-cm data over small regions of sky and could lead to the erroneous conclusion[30] that the observed flux is not of extragalactic origin.

I thank R. Davies, C. Heiles, and B. Tarter for discussions, and acknowledge the financial support of a NATO Postdoctoral Fellowship.

Kilometre and centimetre Earth strainmeters

IT has been customary to construct strainmeters within a length range of 5–500 m (ref. 1). Prior to the instruments reported here the longest instrument was a laser strainmeter 1,020 m long[2] and the shortest also a laser instrument 1 m long[3].

It has been recognised for many years that long strainmeters are desirable for the measurement of strains near the Earth's surface. There are two principal advantages: first, a long strainmeter averages out short wavelength variations in the strain field; second, the signal to be measured increases proportionately with instrument length whereas the 'attachment noise', caused by instabilities in coupling the instrument to the ground, remains constant. The long instrument approach using a laser system has been successfully operated above the Earth's surface[4].

The advantages of short instruments lie in their portability and ease of installation if suitable low noise methods of mounting them to the rock can be used.

The instruments described here are mechanical, remarkably simple and inexpensive. The long instrument is 1,025 m long (thus the longest strainmeter ever built) and the short instrument is 45 cm long and is the shortest ever built. The

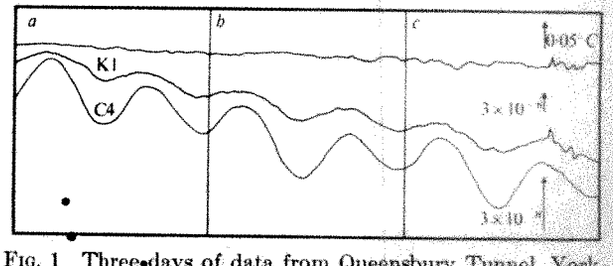

FIG. 1 Three days of data from Queensbury Tunnel, Yorkshire. *a*, September 13; *b*, September 14; *c*, September 15, 1973. K1 is a 1.025 km wire strainmeter and C4 a buried 10 m wire strainmeter. The upper trace is from a thermistor thermometer. Earth strain extension upwards.

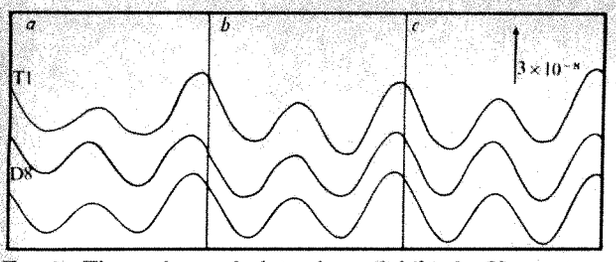

FIG. 2 Three days of data from Schiltach Observatory, Schwarzwald. *a*, January 15; *b*, January 16; *c*, January 17, 1973. The upper trace is from a 45 cm strainmeter (N20E) and trace D8 is from a nearby 10 m wire strainmeter (N2E). The lower trace is the predicted tidal strain (N2E). A linear trend of 3×10^{-8} strain contraction per day has been removed from the observed data.

two strainmeters have operated well for 6 and 12 months respectively.

As a length standard the 1,025 m strainmeter uses a 0.38 mm diameter Invar 36 wire held under constant tension. The wire is supported at approximately 9 m intervals along its entire length by thin wires which constrain vertical and transverse motions but allow longitudinal movements. At each end the strainmeter is attached to the gravel floor of the tunnel by a 20 kg steel plate resting on a thin bed of moist sand. At one end the wire attaches directly to the plate and at the other end a simple weight and lever system provides a constant tension of approximately 15 N. The principle of the tensioning system is the same as for other wire strainmeters developed at Cambridge[5,6]. The resonant modes of the instrument are complex; the amplitude of the fundamental resonant frequency (approximately 0.05 Hz) is reduced by mechanical damping and electronic filtering. A micrometer at one end provides a means of calibrating the instrument but this is only to within 20% due to uncertainties in the restoring force produced at each support point.

We made no attempt to protect the length standard from its environment. Consequently, some parts of the wire are subject to water dripping from the roof and others are exposed to air currents near imperfectly sealed ventilation shafts. Figure 1 shows three days of data. The upper trace records air temperature near the end of the long strainmeter. The lower trace is from a standard 10 m wire strainmeter enclosed in a pipe 50 cm below the tunnel floor. The remaining record is from the long wire strainmeter. Solid Earth tides are clearly seen on this instrument and it is obvious that some of the noise correlates with temperature changes. The higher noise level of the long instrument is not unexpected in view of its exposure to the air, an aspect of the design which clearly can be improved.

An interesting feature of multiple-support wire strainmeters is that within reasonable limits the instrument need not be straight. This ability to tolerate slight lateral or vertical offsets avoids the rigorous site constraints associated with other forms of long strainmeter.

The 45 cm strainmeter uses a 1.5 mm diameter Invar 36 wire as a length standard which is sufficiently stiff to support itself horizontally. The instrument spans a block joint in granite within the Geowissenschaftliches Gemeinschaftsobservatorium at Schiltach in the Schwarzwald, Germany. The purpose of the installation was to observe any anomalous tidal movements between the granite blocks but it has been found that tidal amplitudes are normal. The instrument is attached at each end by an expanding rock bolt. At one end the wire is bolted directly to the granite and at the other end the wire is fastened to an electromagnetic displacement transducer. The calibration of the system is estimated to be not better than ±10%. The output is recorded on a multi-channel chart recorder together with four standard 10 m strainmeters. Three days of record are shown in Fig. 2, together with the predicted tidal strain for Schiltach.

The 45 cm instrument gives a clear tidal record. Its azimuth is 18° different from the 10 m instruments and data from all of these instruments have been spectrally analysed[7]. The amplitude agreement between instruments is within 10% at both diurnal and semi-diurnal periods. The close agreement of the 45 cm strainmeter with the 10 m instruments is surprising since alignment and attachment errors are correspondingly larger in the small device. In some circumstances it is conceivable that an array of colinear small instruments may provide a more representative value than a single larger instrument.

It is possible to use inexpensive mechanical devices as strainmeters with both very short and very long spans. There is no reason to suppose that it is impractical to build strainmeters with dimensions beyond the limits of those described. Whether this ability will prove useful or not is a separate and complicated problem which will only be resolved by experiments with large numbers of instruments.

Earth strain measurement research in Cambridge is supported by the Natural Environment Research Council. The Schiltach Observatory is operated by the Universities of Karlsruhe and Stuttgart.

Production of secondary ice particles during the riming process

ICE crystals play a vital part in the formation of precipitation, particularly outside the tropics, so it is important to know the concentrations of ice particles in natural clouds and to attempt to predict them from measurements made, for example in laboratory cloud chambers, at the same temperature.

There are sometimes large discrepancies, however[1]; for example[2] in maritime cumuli the concentration of crystals can exceed the concentration of ice nuclei as measured in a cloud chamber by a factor of 10^4 at −10° C. One of the oldest explanations[3] for this, revived at intervals[2,4], is that ice particles growing by sweeping up supercooled drops might throw off secondary 'splinters' of ice. Recent laboratory experiments have, however, failed to show any appreciable splinter production in the riming process (ref. 5 and S.C.M., J. L. Brownscombe and G. J. Collins, to be published). We now present new experimental evidence that copious secondary ice particles are thrown off when ice particles grow by riming in clouds at about −5° C. This phenomenon, which occurs under a narrow range of conditions not covered by previous investigators, will probably explain the anomaly.

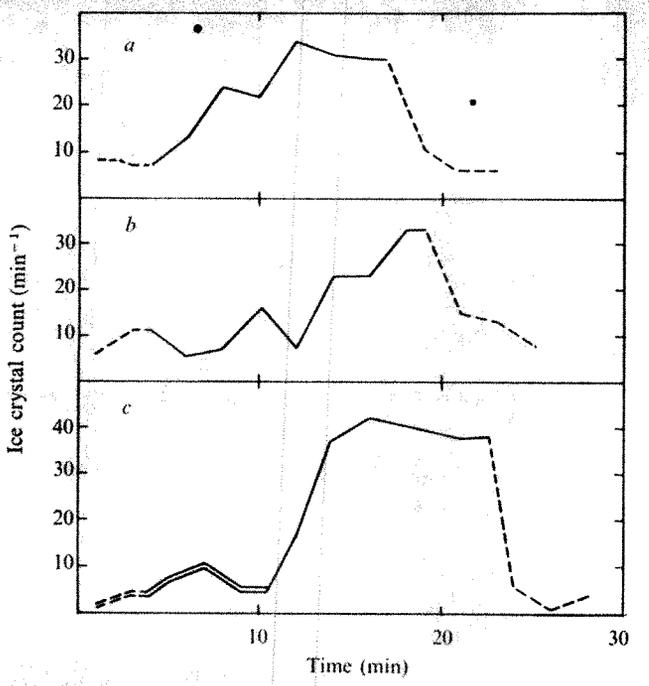

FIG. 1 Production of ice crystals by riming at $-5\pm1°$ C - - -, Target rod stationary; ———, target rod moving at 2.7 m s^{-1}. *a*, Typical experiment with target rod in normal condition; *b*, Target rod coated with glycerin; *c*, Target rod heated above 0° C during period when curve is shown double.

Our experiments were carried out in a plastic walled chamber 1.5 m × 1.5 m × 1.7 m high, enclosed in a cold room. A supercooled cloud of reproducible characteristics was made by injecting steam into the chamber from a boiler run at constant power. Rime was grown on a vertical metal rod 30 cm long and 0.24 cm in diameter which could be moved in a circular path of diameter 30 cm about a vertical axis, at velocities up to about 3 m s^{-1}, in the cloud. The bottom of the riming rod was 64 cm away from the steam inlet at closest approach. Ice crystals could readily be detected by eye in a light beam which traversed the chamber below the riming rod, provided one looked towards the light source at about 10° above or below the beam. With the rod stationary a few crystals per minute appeared in the beam. When the rod was rotated so as to sweep up water droplets which froze and built up as rime on the leading edge, the rate at which crystals appeared increased, to reach an approximately constant value after 4 min. When rotation was stopped, the count of crystals per minute returned to the 'background' value within 4 min. A typical experiment at a cloud temperature of −4.5° C is illustrated in Fig. 1*a*.

Two types of experiment demonstrated that the increase in ice crystal count was indeed caused by the riming and not by some other process, such as the detachment of ice fragments from the walls of the cloud chamber. In the first type of experiment, illustrated in Fig. 1*b*, the target rod was coated with glycerin. The ice crystal counts stayed small for the first 8 min of rotation, then increased when the glycerin had been sufficiently diluted for the supercooled drops to freeze and build up a layer of rime on the rod. In the second type of experiment, illustrated in Fig. 1*c*, the target rod could be heated by an internal electric heater to a temperature above 0° C. No rime grew on the moving rod and the crystal counts increased only slightly above the background value. When the heater was switched off and rime grew on the rod, the counts increased in a way similar to those shown in Fig. 1*a*.

The relationship between the rate of appearance of ice crystals in the light beam and the total rate of production of crystals was established by placing trays of supercooled sugar solution at various positions on the floor of the cloud chamber and counting the number of crystals appearing in the sugar in a given time. A rate of appearance of one crystal in the beam per minute corresponded to a total production rate of 12 crystals per second. The rate of production of secondary crystals (after subtracting the background) was then divided by the rate of accretion of rime to give the number of crystals per milligram of rime.

Figure 2 indicates how the rate of production of ice particles varies with cloud temperature and shows that splinter production is virtually confined to the temperature range −3° C to −8° C. These experiments were carried out at a target velocity of about 2.7 m s^{-1}. As the velocity was decreased, the rate of production of splinters per unit weight of rime increased to a maximum and then fell away to zero at about 0.7 m s^{-1} (Fig. 3).

At a cloud temperature of about −5° C the density of the rime increased with velocity from 0.1 g ml^{-1} at 0.7 m s^{-1} to 0.5 g ml^{-1} at 2.7 m s^{-1}.

By attaching a glass slide, 3 mm wide and coated with MgO, to the riming rod and rotating it at 2.7 m s^{-1} in our experimental cloud at −5° C, we have established that the maximum drop diameter is 35 μm and that such drops are found in a concentration of 0.2 cm^{-3}.

The liquid water content of our experimental cloud was about 1 g m^{-3}, as indicated by an instrument in which the liquid water was evaporated and the resultant dew point measured.

Present experiments shed little light on the physical mechanism by which splinters are produced. The greatest rate of production occurs when the rime surface, being slightly warmer than the cloud, is at about −4.5° C. This is close to the temperature at which ice crystals growing by diffusion show a maximum in the growth rate along the *c* axis and grow as needles or hollow columns[6]. Drop interaction with these extreme crystalline forms may be responsible for splinter formation.

These experiments simulate the growth of graupel particles falling at constant orientation in a supercooled cloud. During the accretion of 1 mg of rime (corresponding to a graupel particle of diameter about 2 mm) several hundred daughter particles may be shed. If each secondary ice particle grows and rimes in its turn, there should be no difficulty in provid-

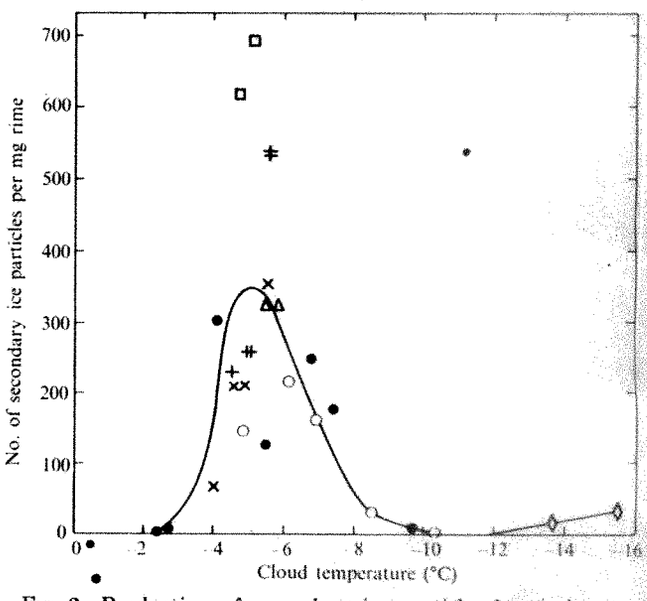

FIG. 2 Production of secondary ice particles by riming as a function of temperature at a target velocity of 2.7 m s^{-1}. Different symbols indicate different days. The curve was drawn by averaging the points over narrow temperature intervals.

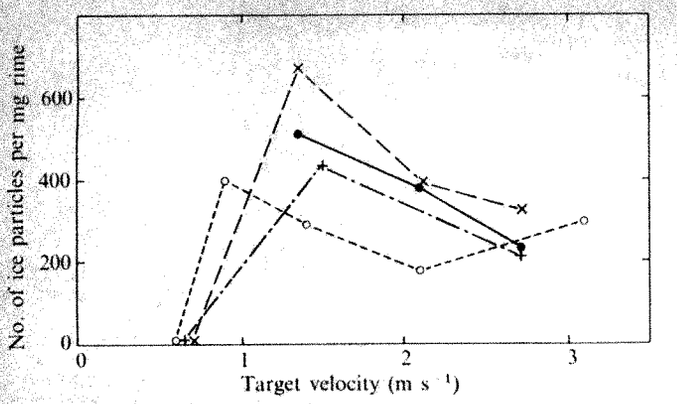

FIG. 3 Production of secondary ice particles by riming as a function of target velocity at a temperature of about −5° C. ●, November 5, 1973; −4.5° C. ×, November 9, 1973; −5.5° C. ○, December 3, 1973; −5.7° C. +, December 5, 1973; −5.2° C.

ing, within a reasonable time, the observed 'multiplication' factor of about 10^4 by which ice crystals sometimes exceed ice nuclei.

We have still to explain why the multiplication process is absent in some natural clouds which span the critical temperature range −3° C to −8° C. In the shallow stratiform clouds sampled by Mossop *et al.*[7], this can be readily explained by the absence of rimed ice particles. The same argument cannot, however, be applied to the winter cumuli over Israel studied by Gagin[8]. These clouds contained plenty of rimed ice particles and also drops up to 36 μm in diameter. Yet there is little evidence of splintering, since the concentrations of ice crystals and ice nuclei agree to within a factor of 10. It may be possible to explain this on dynamical grounds. Maritime cumuli which show comparatively large crystal concentrations are usually wholly below the −10° C level[2], so that much of the graupel growth occurs at temperatures favourable for splintering. In the more vigorous clouds over Israel where the tops reach much colder temperatures, the initial riming growth of graupel particles takes place mainly at temperatures below −10° C. These particles may then fall rapidly, with surface temperature raised by latent heat release. Splinter production apparently requires a surface temperature of about −5° C and therefore depends not only on the ambient temperature of the cloud but also on the fall velocity of the particle and the liquid water content of the cloud[9]. In the Israel clouds the time for which the surface temperature of the graupel particles is close to −5° C may be so short that few secondary ice particles are produced.

We see that the high ice crystal concentrations observed in some cumuli can be explained without postulating earlier growth of the clouds to higher levels[10]: such growth may actually produce smaller concentrations.

The electrical effects accompanying splintering have still to be investigated; they may be important in charge generation in thunderstorms.

Ultra-thin conducting films of gold on platinum nucleating layers

WE report a method for obtaining highly conducting films of noble metals between 11 and 50 Å thick on mica substrates. At the lower limit, the ultra-thin film (11 Å) may consist only of two or three monolayers each of gold and platinum. The minimum thickness at which pure gold films start to conduct is known to be 30 Å (ref. 1). Before this we had found that a pre-nucleating layer of silver, 5 to 7 Å thick, on mica yielded a highly conducting gold overlayer above a total (Au + Ag) thickness of about 32 Å (ref. 2). It was concluded that nucleating layers of suitable materials, of a thickness below which island formation commences, might lead to a higher conductivity in films of total thickness less than 50 Å. In this range, irregularities in the surface of the substrate, for example cleavage steps, become comparable to, or even greater than the film thickness. Cleaved mica surfaces are known to have hill-and-valley type microstructure. The cleavage step heights are about 20 Å or integer multiples thereof[3]. As film thickness decreases to these values, d.c. measurements of conductivity become progressively less accurate. To alleviate this difficulty, we have measured microwave sheet resistance (R_μ in Ω per square) at 9.7 GHz by Slater's method[4]. The corresponding wavelength is more than six orders of magnitude greater than any irregularity in the surface of the mica. We have used this method previously to estimate the conductivity of gold films thicker than 50 Å (ref. 5).

For the work reported here, platinum was selected as the nucleating material; adhesion of platinum to substrates is known to be better than that of silver[6,7]. The films were deposited on to air-cleaved and clear mica sheets less than 0.001 inch thick, from a multi-crucible electron-beam evaporator. The substrates were kept at room temperature (~ 22° C). Eight targets were placed around the axis of the vapour beam at 50 cm from the source in a manner calculated to deposit films of equal thickness[8]. The mass-thickness of the films was monitored by a quartz crystal microbalance with the AT-cut, 5 MHz crystal placed in the centre of the targets. The crystal plate (0.75 inch-square, 1 mm thick) has a mass-frequency proportionality constant, C_f, of 57.6 Hz cm² μg⁻¹ (ref. 9) giving a sensitivity of 11.13 Hz Å⁻¹ for gold and 12.36 Hz Å⁻¹ for platinum; the bulk and film densities were assumed to be the same. The oscillator frequency was measured by a digital frequency counter and recorded on a chart through a digital-to-analogue converter to ascertain frequency stability. With the crystal seat temperature stabilised by flowing water, the maximum frequency drift recorded over a period of 12 h was ± 5 Hz. At an electron-beam power between 500 to 600 W, the deposition rate was typically 0.5 Å s⁻¹ for both metals. Films were thus deposited in a few seconds but, because the effects of thermal shock[10] lasted more than 5 min, continuous monitoring of rate and

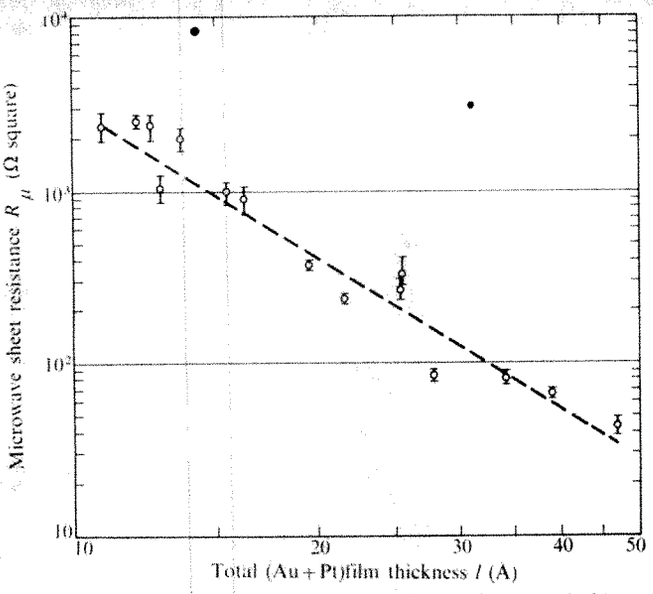

FIG. 1 Microwave sheet resistance, R_μ, against total (Au + Pt) thickness, l. ———, $R_\mu = 2.77 \times 10^6\ l^{-2.944}$ with a correlation coefficient of 0.96.

thickness was not possible. Deposition times were estimated and the difference between the stable pre- and post-deposition frequencies was used to compute the actual film thickness. The starting vacuum was $< 10^{-7}$ torr; the pressure rose to $\sim 5 \times 10^{-6}$ torr during deposition.

Using this method, gold films of varying thicknesses were deposited on to platinum nucleating layers ranging in thickness from 3 to 10 Å. A mean value of R_μ for sets of eight films deposited simultaneously is plotted against the total (Au + Pt) thickness, l, in Fig. 1. The adjusted standard error in R_μ is shown for each set of eight films; l is taken to be accurate within the limits of oscillator stability, that is ± 0.5 Å.

The conduction in these films was found to end abruptly for values of l less than 10.8 Å. Combinations of gold and platinum thicknesses to lower this limit by even 1 Å were not successful. It may, however, be noted that the sticking coefficient, α, of the evaporated films decreases rapidly with increasing lattice mismatch between the substrate and evaporant materials[11]. α also depends on thickness and approaches unity above 250 Å; values for α are not known at 10 Å. The actual thickness of the film of 10.8 Å may, therefore, be only three or four monolayers and conducting films of smaller thickness may not be feasible. The colour of the films obtained varied from light grey at 11 Å to greenish-grey as l approaches 50 Å.

We found that using gold as a nucleating layer did not produce ultra-thin, conducting films of platinum in this range.

It is known that the interatomic forces of attraction between the evaporant atoms, of gold or platinum in this case, cause liquid-like coalescence and consequent island formation, resulting in discontinuous films at thicknesses less than 50 Å. We postulate that, before the onset of island formation, a monolayer or so of a suitable nucleating material has the adatoms locked in the potential well sites on an ionic substrate surface. These then form an effective barrier against surface migration of the oncoming gold atoms and thus induce film growth in monolayers rather than discrete three-dimensional nuclei. The method may also be one with which to induce epitaxy. The choice of nucleating material seems critical.

Preliminary annealing studies on gold-on-platinum films 25 Å thick showed a slight decrease in R_μ up to 210° C; above this temperature R_μ increased slightly. The resistance of gold films alone increased irreversibly with temperature. Although detailed *in situ* electron microscopy and diffraction studies[12] will be necessary to obtain direct evidence, the high electrical conductivity and annealing behaviour of films of gold on platinum may be taken as a reasonable indication that these are continuous. Further work on the ageing and annealing properties, together with a determination of the temperature coefficient of resistance of these films, is in progress. Other nucleating materials are also being investigated.

Our research is supported by the National Research Council of Canada. We thank Edward Buck, George Fij, Herbert Gans, Albert Huizinga and Conrad Walker for technical help and discussions.

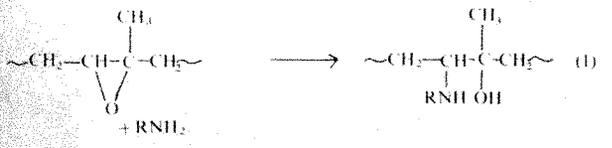
Epoxy groups responsible for crosslinking in natural rubber

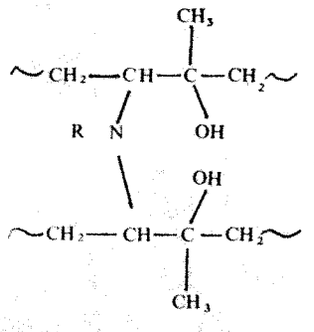
STORAGE hardening in natural rubber, which is of considerable industrial interest, has been ascribed to the crosslinking of carbonyl groups present in the rubber chain[1]. Supporting evidence is that the crosslinking reaction can be prevented or accelerated by the addition of monofunctional or difunctional amines, respectively. These observations may be explained if the monofunctional amine is regarded as condensing with, and hence destroying, the carbonyl group, whereas the difunctional reagent is capable of reaction with carbonyl groups on separate chains, thus effecting a crosslink. The ability of dimedone (5,5-dimethylcyclohexane-1,3-dione) to inhibit the crosslinking reaction led to the conclusion that the groups were aldehydic[1].



Involvement of aldehyde groups in storage hardening necessitates the presence of complementary 'aldehyde condensing groups' (for example, amino groups) on the macromolecule[2]. It is not easy to account for the presence of aldehyde groups, let alone 'aldehyde condensing groups', on the natural rubber molecule in terms of the known biosynthetic pathways for isoprenoid compounds.

Can other functional groups account for this behaviour? The presence of epoxy groups can provide a mechanism for storage hardening. Epoxidation of the olefinic double bond

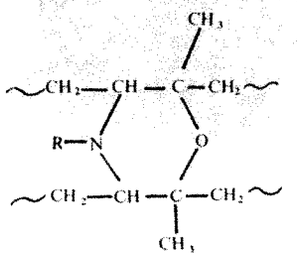
has ample precedents among naturally occurring compounds. All classes of terpenoid compounds (with the exception, hitherto, of natural rubber itself) include members that have epoxide groups, and they are found also on the isoprenyl residues of some other compounds of mixed biogenetic origin. Direct evidence for epoxide groups in natural rubber is presented later in this paper.



Storage hardening may be envisaged to occur by the following reactions:

(1) Epoxy groups are ring opened by naturally occurring amino-compounds in the latex, for example

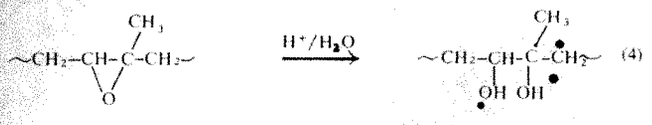
(1)



(2) This substituted amine could interact with an epoxy group on an adjacent chain with formation of a crosslink such as

(2)

which may be partially formed at the latex stage.



(3) During storage and drying, ring closure of the product of reaction (2) could occur, forming an additional crosslink, for example, the cyclic structure

(3)

The presence of epoxy groups is fully consistent with the experimental results, which apparently favoured aldehydic groups, since ring opening of epoxy groups by amines is well known[3]. Similarly the reactions of epoxides with active hydrogen compounds analogous to dimedone have been reported[4].

Furthermore the present proposals provide insight into the previously unexplained observations that the addition of sodium azide as a preservative to rubber latex leads to a decrease in the number of 'condensing groups'[2], and that conditions of low *p*H during coagulation of the latex reduces the extent of crosslinking on storage[5]. The former is readily explained since the azide ion cleaves epoxide rings to the β-azido alcohol[6]. Similarly the latter observation may be attributed to ring opening of epoxy groups under acidic conditions, for example

(4)

The resulting glycols have no crosslinking ability.

The presence of epoxy groups in natural rubber was demonstrated by making use of reaction (4). A fresh latex sample was treated with acid in order to ring open the epoxide links. The resulting 1,2-diols were cleaved with lead tetraacetate by a method analogous to that used by Flory and Leutner[7]. The chain scission resulting from oxidation of the 1,2-diols was detected by viscometry. The intrinsic viscosity $[\eta]$ of a chloroform solution of the natural rubber sample, at 30° C, before and after treatment with lead tetraacetate is 3.75 and 0.39, respectively.

It is immediately apparent that considerable degradation has occurred. Unforunately, the parameters of the Mark-Houwink viscosity equation for natural rubber in chloroform are not available but, if a reasonable value of $\alpha = 0.7$ is assumed, then the decrease in viscosity corresponds to a decrease in molecular weight by a factor of about 14. This in turn leads to an average number of about 13 epoxy groups per chain. The value is only approximate since not all of the epoxy groups may have ring opened but nevertheless it seems significant that the value is of the same order as that reported previously for 'aldehyde groups' in natural rubber[8].

That the decrease in molecular weight, on degradation with lead tetraacetate, is due to the cleavage of 1,2-diols rather than oxidation of the double bonds is suggested by the rapid reaction, degradation being essentially complete within 30 min. Although oxidation of double bonds by lead tetraacetate has been reported, the reaction is slow and addition products rather than bond cleavage are observed[9].

BIOLOGICAL SCIENCES

Geographical uniformity of selectively neutral polymorphisms

In a recent issue of *Nature*, Bulmer[1] criticised the 'neutral theory'[2] of protein polymorphisms on the ground that the infinite neutral allele hypothesis of Kimura and Crow[3], when combined with Malécot's two-dimensional dispersal model[4,5] leads to results which do not fit to actual data[6–8]. In this note, we intend to show that Bulmer's conclusions are entirely due to the unwarranted assumption of infinite population size inherent in Malécot's formulation, and that when the assumption is corrected, the data in fact are consistent with the neutral theory.

Bulmer claims that there are two contradictions. First, if we use Malécot's formulae for a continuous two-dimensional dispersal model, we get a rather strong geographical localisation of allele frequencies, whereas considerable uniformity is observed in the data. He uses Malécot's two quantities: the inbreeding coefficient (f_0) defined as the probability that

two homologous loci in an individual are identical by descent, and the coefficient of kinship (f_x) defined in a similar way, between two individuals at a distance x apart. Using Malécot's formula for f_0 and f_x which are valid only for a population distributed over a two-dimensional habitat of infinite size, Bulmer calculates the ratio, $\rho_x = f_x/f_0$. The numerical values of ρ_x presented in his examples certainly decreases quite rapidly as x increases. On the other hand, the estimates of this ratio using data from *Drosophila pseudoobscura* are very close to unity even for far distant localities, such as Texas, Colorado and California. He claims then that such a discrepancy cannot be resolved except under the absurd assumption that the root mean square dispersal distance, σ, is of the order of 2,000 km.

Secondly, he points out that the expected degree of homozygosity (f_0) would be much less than that of the data, unless the gene dispersion is very restricted. The average homozygosity found by Prakash *et al.*[6] is 0.877. Bulmer claims, using Malécot's formula for f_0, that to make f_0 to be about this magnitude, the mean square dispersal distance between the breeding places of parent and offspring (σ^2) must be an absurdly small value. For example, if the nutation rate u is 10^{-5}, then the number of flies within a circle of radius σ, that is $\pi\sigma^2\delta$, is about 0.38. This seems to be not only untrue but if the dispersion is restricted to this degree, ρ_x should decrease very rapidly.

It is important to realise that Malécot's formulae used by Bulmer are valid only for cases where the total population number (N) is much greater than the reciprocal of mutation rate (u) and the habitat is large. The size of habitat alone, however, is not sufficient, as long as the population is finite. Of course, if the population is truly infinite, his formulae are valid. On the other hand, if N and $1/u$ are about the same order of magnitude, it is necessary to use formulae valid for a finite population. For such a population, Malécot's formulae cannot be used even as an approximation, because they give entirely different values. Exact analysis for a finite case of torus-like space of size $L_1 \times L_2$ was obtained by Maruyama[9]. For a more realistic case of a rectangular habitat of size $L_1 \times L_2$, although exact solutions were not obtained, it turned out that they can be approximated by solutions of the torus-like space of size $2L_1 \times 2L_2$ (ref. 9). So, we use the torus-like space in the following discussion. If we designate position in the space by Cartesian coordinate system and let $f(x, y)$ be the probability that two homologous genes separated distance x and y along the first and second axes respectively are identical by descent, then

$$f(x, y) = \frac{(1-u)^2(1-f_0)}{2\delta L_1 L_2} \cdot \sum_{m=0}^{\infty}\sum_{n=0}^{\infty} \frac{\Delta_m \Delta_n R_{mn}}{[1-(1-u)^2 R_{mn}]} \cos\frac{2\pi m x}{L_1} \cos\frac{2\pi n y}{L_2} \qquad (1)$$

where $\Delta_0 = 1$ and $\Delta_k = 2$ if $k \neq 0$, δ is the population density and

$$R_{mn} = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} r(\xi, \eta) \cos\frac{2\pi m\xi}{L_1} \cos\frac{2\pi n\eta}{L_2} \, d\xi \, d\eta$$

in which $r(x, y)$ is the probability that a zygote is formed between gametes of parents born distance $\sqrt{(x^2 + y^2)}$ apart. As a special case, if $r(x, y)$ is a two-dimensional normal density and the migration is isotropic,

$$r(x, y) = \frac{1}{2\pi\sigma^2} \exp\left[-(x^2 + y^2)/(2\sigma^2)\right], \qquad (2)$$

and

$$R_{mn} = \exp\left[-2\pi^2\sigma^2(m^2/L_1^2 + n^2/L_2^2)\right]$$

TABLE 1. Theoretical values of the inbreeding coefficient and genetic correlation

$4Nu$	N	u	$\sigma^2\delta$	f_0	Furthest distance possible/σ	f_{min}^*/f_0

40.0	10^7	10^{-6}	5	0.1674	1000	0.6818
100.0	2.5×10^7	10^{-6}	50	0.0263	500	0.3308

* f_{min} is the kinship coefficient between two individuals furthest apart.

In our formula (1), f_0 is involved implicitly, but it can be determined explicitly,

$$f_0 = \frac{(1-u)^2 S}{2\delta L_1 L_2 + (1-u)^2 S} \qquad (3)$$

where

$$S = \sum_{m=0}^{\infty}\sum_{n=0}^{\infty} \frac{\Delta_m \Delta_n R_{mn}}{[1-(1-u)^2 R_{mn}]}$$

Using formulae (1) and (3) with $r(x, y)$ given by (2), and assuming $L_1 = L_2$, we have carried out extensive numerical calculations using our computer TOSBAC 3400. Contrary to Bulmer's claim, we found that theoretical expectations and data are consistent. If Nu is 1 or less and $\sigma^2\delta$ is of order of 100 or 10 or even less, ratio $f(x, y)/f_0$ stays very close to 1 and it is roughly independent of distance and habitat size. Here, a remark on mutation rate is in order. As pointed out by Kimura and Ohta[2], the appropriate mutation rate for neutral alleles is at most 10^{-7} per yr per locus. So, for *Drosophila* whose generation time is some 2 weeks, we should take $u = 10^{-8}$ or less to be consistent with the neutral theory. From these assumptions, it also follows that if we take $4Nu = 0.1 \sim 0.2$, the value of f_0 turns out to be about right order of magnitude consistent with the neutral theory[2]. Note here that N represents the effective population size rather than the actual size. Numerical examples are presented in Table 1, where f_{min} is the kinship coefficient between two individuals furthest distance apart. It should be emphasised that the finiteness of population makes the situation completely different from that of a truly infinite case. Thus, Bulmer is unwarranted in using Malécot's formulae which led him to the erroneous conclusions which seem to be inconsistent with data: Bulmer's dilemma is entirely due to an incorrect assumption of infinite population, but this can be simply resolved by the correct assumption. This may be evident by comparing values in column f_{min}/f_0 of Table 1 in this paper with his tables.

It seems appropriate to discuss here the influence of the dimensionality of space on these properties. Through numerical calculations, we found that a two-dimensional population tends to be nearly panmictic, particularly if $4Nu$ is order of 1 or less, and that panmixity can be attained easily. As a consequence, f_0 is related to N almost directly. On the other hand, in an one-dimensional (or a long but narrow) population, the situation is quite different, and the local differentiation appears, if $\sigma^2\delta$ is small compared with the habitat length. When the habitat size is sufficiently long, the value of f_0 becomes nearly independent of the total popula-

tion size. In such a circumstance, a formula derived assuming an infinite population size gives approximately correct values for f_0 and f_x. But as long as the value of f_0 is influenced by the total size, which is often the case in a two-dimensional population, the finiteness must be taken into account. This is where Bulmer has made an error. We conclude that the pattern of geographical distribution of protein polymorphisms in *Drosophila* as discussed by him is indeed consistent with the neutral theory.

Enzymatic acylation of histidine to mengovirus RNA

PLANT virus RNA from the TYMV family[1–3], TMV[4,5] and BMV[6] can be enzymatically esterfied with valine, histidine and tyrosine, respectively. The aminoacylation of intact or fragmented plant virus RNA[7], may be an important biological function and, therefore, the question as to whether some mammalian viral RNA can be charged with amino acids becomes significant. In this work, we show that mengovirus RNA can, in fact, be specifically acylated with histidine by a mouse liver aminoacyl-tRNA synthetase preparation.

Mengovirus was grown in mouse L-929 cells (clone CCL1) and precipitated by polyethylene glycol. The virus particles were purified by banding in CsCl before the extraction of viral RNA (see legend to Fig. 1). This step was found to be important for the elimination of any contaminating cellular tRNA. To test the homogeneity of the viral RNA, samples were analysed by electrophoresis on polyacrylamide-agarose gels[8,9]. No detectable amounts of RNA of low molecular weight could be found in the viral RNA preparation. The apparent molecular weight of the mengovirus RNA was estimated as 2.3×10^6, by comparing its migration with that of TMV RNA and total *E. coli* RNA (Fig. 1). Our value for the molecular weight differs slightly from previous values for mengovirus, which were based on hydrodynamic measurements (1.74×10^6, ref. 10) or sucrose density gradient sedimentation analyses (2.8×10^6, ref. 11).

Mengovirus RNA can be acylated with a mixture of 16 amino acids by mouse liver aminoacyl-tRNA synthetase (Table 1). On the other hand, MS2 bacteriophage RNA or mouse liver rRNA are not aminoacylated under the same experimental conditions. It is interesting that the heterologous aminoacyl-tRNA synthetase from *E. coli* failed to acylate mengovirus RNA, MS2 bacteriophage RNA or TMV RNA. Mengovirus RNA was found to be esterified solely with histidine by the mouse liver aminoacyl-tRNA synthetase preparation. This was deduced from the finding that the acylation of mengovirus RNA with a mixture of labelled amino acids is hardly suppressed by the addition of excess non-radioactive mixture of amino acids lacking histidine, whereas the addition of excess non-radioactive histidine completely inhibited the reaction.

We have devised an electrophoretic method to determine the size of individually labelled aminoacylated tRNA species.

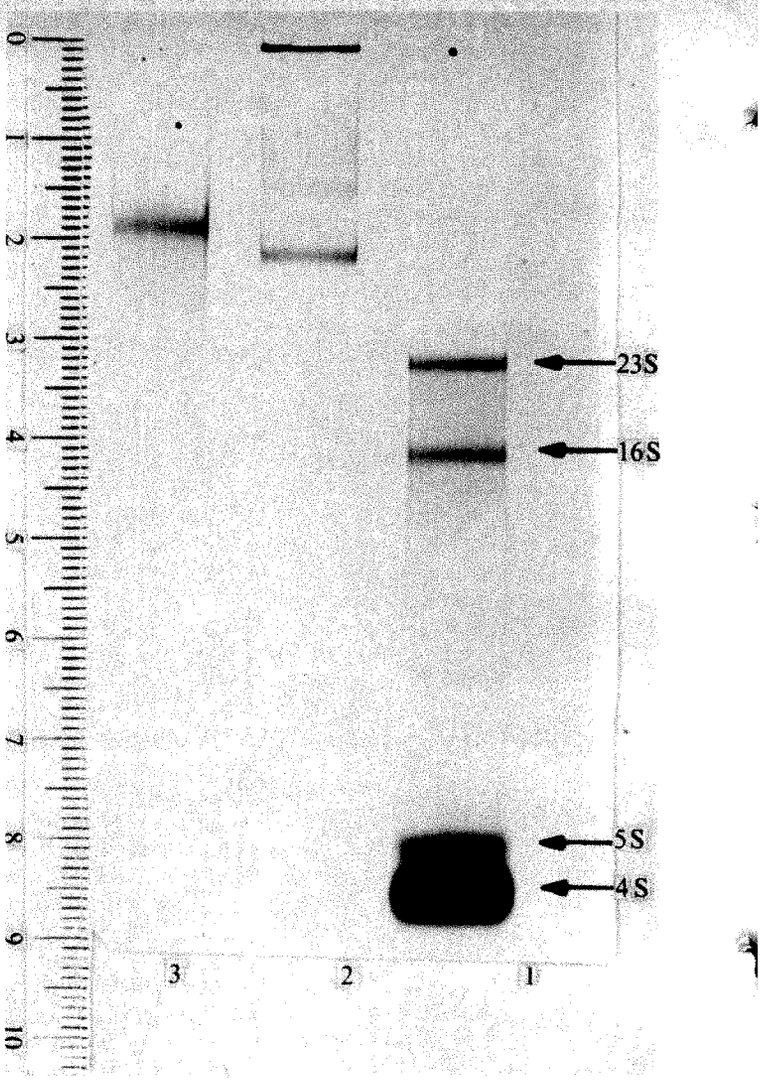

FIG. 1 Polyacrylamide-agarose gel electrophoretic patterns of mengovirus RNA, TMV RNA and total *E. coli* RNA. Confluent monolayers of mouse L-929 cells (clone CCL1) were infected with 2 PFU per cell of mengovirus. After incubation for 1 h at 37° C, 40 ml of Eagle's MEM containing 8% calf serum was added to each 200 cm² bottle. Incubation was continued for 18 h, at which time the cell mass was dislodged by gentle shaking. The suspension was frozen and thawed and the lysate was freed of cell debris by centrifuging at 1000*g* for 5 min at 4° C. The mengovirus suspension was supplemented with 6% polyethylene glycol (6000, Union Carbide) and 0.01% β-mercaptoethanol and stirred at 0° C for 1 h. The precipitate was collected by centrifugation at 12,000*g* for 20 min and suspended with the aid of a glass-teflon homogeniser in 100 mM Tris-HCl, *p*H 7.9 and 10 mM EDTA[11]. The density of the suspension was adjusted to 1.332 g cm^{-3} with CsCl and the virus particles were banded by centrifugation at 40,000 r.p.m. in a type 40 fixed angle rotor in a Beckman Model L ultracentrifuge for 18 h. The band containing the virus particles was collected, diluted three-fold with water and centrifuged for 2 h at 40,000 r.p.m. The RNA was isolated from the virus suspension by phenol–chloroform extraction, followed by ethanol precipitation[15]. Each RNA (1.0–5.0 μg) sample was applied to an 1.7% polyacrylamide–0.5% agarose slab gel. Electrophoresis was carried out for 2.5 h at 0° C at 11.4 V cm^{-1}. The gels were stained with Stains all[9]. Slot 1, Total *E. coli* RNA; slot 2, TMV RNA; slot 3, menogovirus RNA.

To preserve the aminoacyl-RNA ester bond, the aminoacyl-RNA was acylated with N-hydroxysuccinimide acetyl ester to yield N-acetylaminoacyl-RNA. We synthesised the latter, since N-substituted aminoacyl-tRNA derivatives have been shown to be considerably more resistant to hydrolysis than the corresponding unblocked aminoacyl-tRNA derivatives (compare ref. 12). Using N-acetyl-^{3}H-aminoacyl-tRNA molecules, we have been able to estimate their size by monitoring the radioactivity of the sliced gel. Under these conditions, unblocked aminoacyl-tRNA molecules are completely hydrolysed. Figure 2*a* shows the electrophoretic migration of mouse liver N-acetyl-^{3}H-histidyl-tRNA. The electrophoretic pattern of mengovirus RNA bound to N-acetyl-^{3}H-histidine, and run in parallel on the same gel, is shown in Fig. 2*b*. The size of the major RNA peak bearing ^{3}H-histidine, was estimated to be between 0.20×10^6 to 0.35×10^6 daltons. In addition, a small part of the ^{3}H-histidine was attached to RNA of molecular weight 1.25×10^6. When the mengovirus N-acetyl-^{3}H-histidyl-RNA preparation was treated with pancreatic RNase and then analysed by gel electrophoresis, no radioactivity could be detected in the various gel slices.

From these results it is clear that the mengovirus RNA is enzymatically acylated with histidine. It seems that mengovirus RNA is cleaved during the aminoacylation reaction, probably because of contamination of the crude mouse liver aminoacyl-tRNA synthetase preparation with traces of endo-

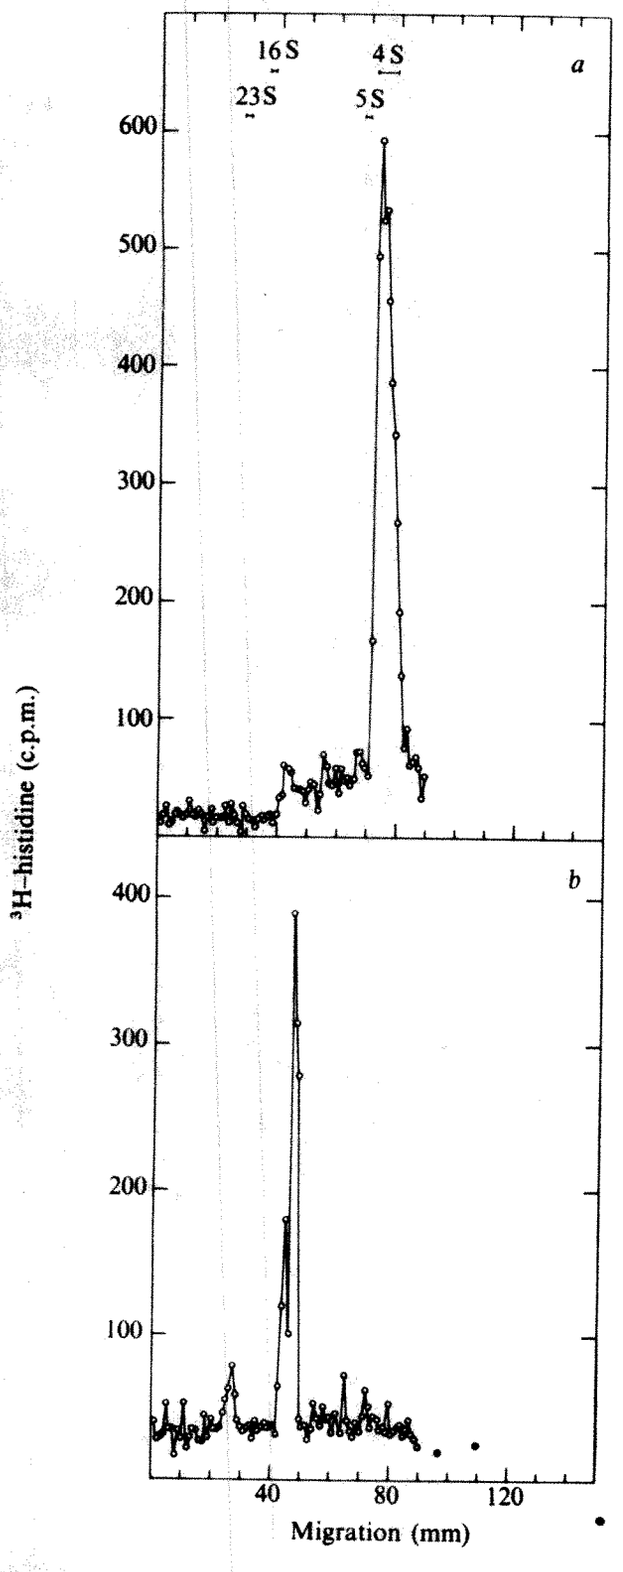

TABLE 1 Aminoacylation of viral RNAs

Source of RNA	Amino acids	Amino acids incorporated (c.p.m. per 10 μg RNA) Mouse liver synthetase	*E. coli* synthetase
Mengovirus	^{3}H-mixture	2,000	170
TMV	^{3}H-mixture	4,800	270
MS2 bacteriophage	^{3}H-mixture	40	190
Mouse liver rRNA	^{3}H-mixture	80	—
Mengovirus	^{3}H-mixture + unlabelled 15 amino acid mixture lacking histidine	1,900	—
Mengovirus	^{3}H-mixture + unlabelled histidine	60	—
Mengovirus	^{3}H-histidine	3,600	—
TMV	^{3}H-histidine	7,800	—

The incubation mixture (0.05 ml) contained: 20 mM Tris-HCl, *p*H 7.5, 1 mM ATP, 10 mM $MgCl_2$, 3 mM dithiothreitol, 0.5 μCi of a mixture of 16 ^{3}H-labelled amino acids (^{3}H-reconstituted protein hydrolysate, Schwartz/Mann, consisting of alanine, arginine, cystine, glycine, histidine, hydroxyproline, isoleucine, leucine, lysine, methionine, phenylalanine, proline, serine, threonine, tyrosine and valine) or ^{3}H-histidine (58 Ci mmol^{-1} Amersham), 10–20 μg RNA and 50 μg mouse liver aminoacyl-tRNA synthetase, or 5 μg of partially purified mouse liver histidyl-tRNA synthetase or 5–10 μg of an *E. coli* enzyme preparation. Where indicated, a mixture of 0.08 mM each of 15 unlabelled amino acids or 0.08 mM histidine was added. The incubations were carried out at 37° C for 30 min. The reaction was stopped by the addition of 0.5 ml of bovine serum albumin solution (0.25 mg) followed by precipitation with cold 5% trichloroacetic acid. The precipitate was filtered through glass filters (Whatman GF/C) washed and counted. The mouse liver aminoacyl-tRNA synthetase was partially purified from a 105,000*g* supernatant by phase partition[13]. The mouse liver histidyl-tRNA synthetase was further purified by DEAE-cellulose chromatography. The *E. coli* aminoacyl-tRNA synthetase was prepared according to Muench and Berg[14].

FIG. 2 Polyacrylamide–agarose gel electrophoresis of mouse liver N-acetyl-(^{3}H-histidyl-tRNA (*a*) and mengovirus N-acetyl-^{3}H-histidyl-RNA (*b*). Mouse liver tRNA and mengovirus RNA were acylated with ^{3}H-histidine (58 Ci mmol^{-1}) with mouse liver histidyl-tRNA synthetase, as described in the legend to Table 1. To 0.05 ml of the labelled aminoacyl-RNA solution, 0.025 ml of 1 M sodium acetate, buffer, *p*H 4.2 and 0.15 ml of ethanol were added. The precipitated RNA was dissolved in 0.025 ml of 0.01 M sodium acetate buffer, *p*H 5.0 and a solution of 0.05 ml of dimethylsulphoxide containing 5 mg of N-hydroxysuccinimide acetyl ester was added. The mixture was then treated as previously described[12]. The mouse liver N-acetyl-^{3}H-histidyl-tRNA (663 c.p.m. μg^{-1}) and the mengovirus N-acetyl-^{3}H-histidyl-RNA (179 c.p.m. μg^{-1}) preparations were applied to two different slots on a 1.7% polyacrylamide–0.5% agarose slab gel. In a third slot 5 μg of total *E. coli* RNA was added. Electrophoresis was carried out for 2 h at 0° C at 11.4 V cm^{-1}. The gel was stained with Stains all and then sliced into 1 mm fractions. Each slice was transferred to a 3.5 ml vial, incubated with 0.3 ml NCS (Amersham/Searle) for 30 min at 20° C and then 3 ml of toluene-based scintillation fluid was added. The vials were inserted into standard 20 ml scintillation vials and counted in a Packard Tricarb scintillation counter.

nucleases. It is still not clear whether specific cleavage of mengovirus RNA is required for its histidine-acceptance activity. The aminoacylated mengovirus RNA fragments have, however, a much larger molecular weight than that of tRNA and, thus, the possibility of tRNA contamination can be excluded. Moreover, the reaction of mengovirus histidyl-RNA with N-hydroxysuccinimide acetyl ester was carried out in 66% dimethylsulphoxide. Under these conditions any contaminating non-covalently linked tRNA would have been dissociated from the mengovirus RNA.

To estimate the extent of mengovirus acylation, we have increased the histidine concentration in the acylation mixture by using ^{14}C-labelled histidine (Schwartz/Mann 342 mCi mmol^{-1}). Under these conditions, 0.18 mol histidine are acylated per mol of mengovirus RNA, as compared with a value of 0.30 mol obtained with TMV RNA. The latter value confirms the results of Litvak *et al.*[5].

In this study we have shown that specific aminoacylation of viral RNA is not confined only to plant viruses. It will be interesting to determine whether other mammalian viral RNA preparations also serve as acceptors for amino acids. In the case of poliovirus RNA, no aminoacylation could be detected by Öberg and Philipson[4]. Whether this is due to the nature of poliovirus or to differences in the aminoacylation system remains to be determined.

The biological function of the amino acid acceptor activity of plant virus and mengovirus RNA is not known. It is possible that the aminoacylation of these viral RNA species may have some regulatory function in protein synthesis or that aminoacyl-RNA may be involved in the recognition site of viral RNA replicase.

Structure of inositol hexaphosphate–human deoxyhaemoglobin complex

D-2,3-Diphosphoglycerate (DPG) facilitates the transfer of oxygen from human red blood cells to the tissues by lowering the oxygen affinity of haemoglobin[1]. It does so by combining preferentially with one of the two alternative forms of haemoglobin, namely the deoxy form, in the ratio of 1 mol per mol tetramer. Its binding site was predicted from biochemical and model building experiments and then determined directly by X-ray crystallography[2]. The site lies at the entrance to the central cavity between the N-termini of the β chains and is surrounded by four pairs of basic groups: the α amino group of valine 1 and the side chains of histidines 2 and 143, and of lysine 82. The basic groups are related in pairs by the molecular dyad and arranged so as to complement the acidic groups of DPG by forming seven salt bridges (Fig. 1). On oxygenation the N-termini of the β chains move apart and the cavity closes up so that the stereochemical complementarity is lost[3]. Oxyhaemoglobin does also bind DPG, but much more weakly, and the binding site is still unknown.

Several other multivalent anions, including inositol hexaphosphate (IHP), ATP, GTP and $[Fe(CN)_6]^{4-}$, also lower the oxygen affinity of haemoglobin. The most effective and biologically also the most important of them is IHP, as it is closely related to the inositol pentaphosphate which takes the place of DPG in regulating the oxygen affinity of bird erythrocytes[4,5]. We have determined the binding site of IHP by X-ray analysis and model building. Its six phosphate groups are coordinated to the same basic groups of the β chains as the single carboxyl and the two phosphates of DPG, and the binding of the two compounds also produces similar changes in the tertiary structure of the β subunits.

Crystals of human deoxyhaemoglobin were prepared by the method of Perutz[6], except that the ammonium phosphate normally added to the more than 2 M ammonium sulphate solution was replaced by 20 mM IHP at *p*H 6.5. At this high ionic strength, however, IHP failed to bind. The crystals were therefore soaked for 1 d in an aqueous solution of 70% (v/v) 2-methyl-2,4-pentanediol (MDP) + 1 mM IHP + 20 mM bis Tris adjusted to *p*H 6.5 with HCl. Other crystals were grown in the standard way (that is, without IHP) and soaked in a solution of 70% MPD + 20 mM bis Tris at *p*H 6.5. The structure of the haemoglobin molecules in such crystals is the same as that in crystals suspended in concentrated ammonium sulphate[2]. The intensities of about 14,000 reflections within a limiting sphere of 3.5 Å^{-1} from crystals in MPD with and without IHP were measured on a Crystalign four-cycle diffractometer. A difference Fourier synthesis was calculated using ($|F_{+\text{IHP}}| - |F_{-\text{IHP}}|$) as the coefficients to-

Solid contours and upper case letters mark positive difference density; broken contours and lower case letters, negative difference density.

gether with the phase angles determined by Muirhead and Greer[7].

The difference electron density map is dominated by a massive and markedly asymmetrical positive peak at the entrance to the central cavity between the N termini of the β chains. The asymmetry may be an artefact, because the dyad axis passing through the centre of the haemoglobin molecule is not a crystallographic one, so that errors in intensity measurement and in phasing have different effects on points in the electron density which are related by the molecular dyad, but are not crystallographically equivalent. The difference map was therefore averaged about the molecular dyad, as in the previous study of DPG, and then sampled in planes 1 Å apart perpendicular to that axis.

Figure 2 shows a projection of several sections of the symmetry-averaged map. The large difference peak is cross shaped and has its maximum at a level 12 Å below that of the iron atoms in the β subunits. To find the orientation of the IHP molecule, a model built according to the structure of its sodium salt[8] was viewed against the difference map in same Richards box[9] in which a model of human deoxyhaemoglobin had been constructed (A. A., L. F. Ten Eyck, and G. Fermi, unpublished). The model of IHP fitted the difference map only with the cyclohexane ring parallel, but not perpendicular, to the dyad, and it fitted well with the line joining phosphorus atoms 3 and 6 normal to the dyad and inclined at an angle of 32° to x (Fig. 3). An equally good fit can be obtained after rotating the model by 120° so that phosphate 1 occupies the place of 3, and 4 that of 6. The distance between the phosphorus atoms of either of these two phosphates is 7.5 Å as compared to 6.5 Å between those of fully stretched DPG (Fig. 1). In either of these orientations our very limited resolution allows some latitude for rotation of the individual phosphate groups about both the C–O and the O–P bonds and therefore the fit should not be regarded as strong evidence in favour of the conformation of IHP in deoxyhaemoglobin being exactly the same as in the crystals of its sodium salt.

Phosphates 3 and 6 fit in well between the two α amino groups, which are 4 Å from the nearest phosphate oxygen in the undistorted deoxy structure (Fig. 4). This distance is too large for salt bridges, so that IHP (and DPG) pull the two α amino groups closer together. The evidence for this comes from a pair of positive (P1) and negative (p1) peaks which straddle the native electron density peaks of valines 1β, showing that the N termini move towards the phosphates; and peaks P5 and p5 which show that the entire A helix moves towards the centre of the molecule. Peaks P2 and p2 show that histidines 143β also move towards the phosphates. As in the DPG map, a large negative peak (P4) overlaps a peak in the native density, indicating that the atoms represented by that peak are removed by IHP. The peak lies outside the density representing the protein and is probably due to an inorganic anion, either sulphate or phosphate, bound to the α amino groups in the absence of IHP. Unlike the DPG map, the IHP map shows hardly any movement of lysine

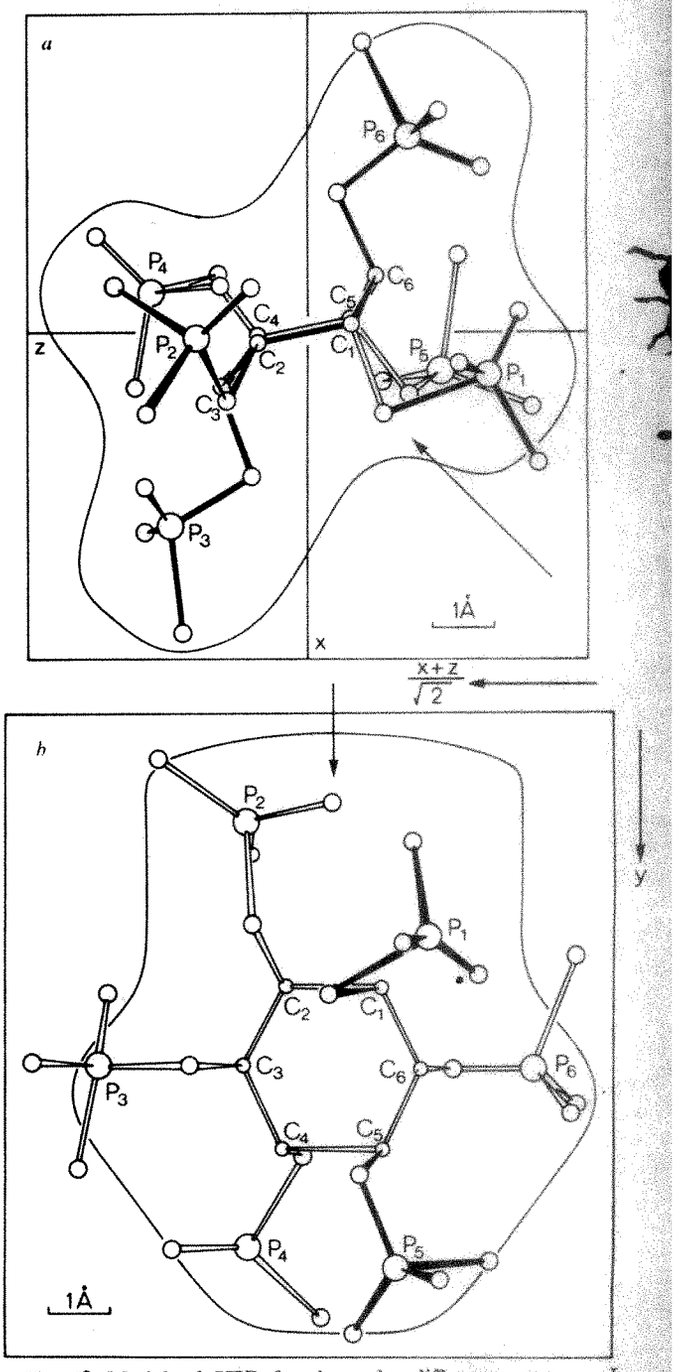

FIG. 3 Model of IHP fitted to the difference map. *a*, In projection on a plane normal to the molecular dyad superimposed on the outline of the central section ($y = -19$) through the difference peak. *b*, In projection along the diagonal between x and z against the outline of the central section through the difference peak. The arrow in (*b*) shows the direction of view in (*a*) and *vice versa*.

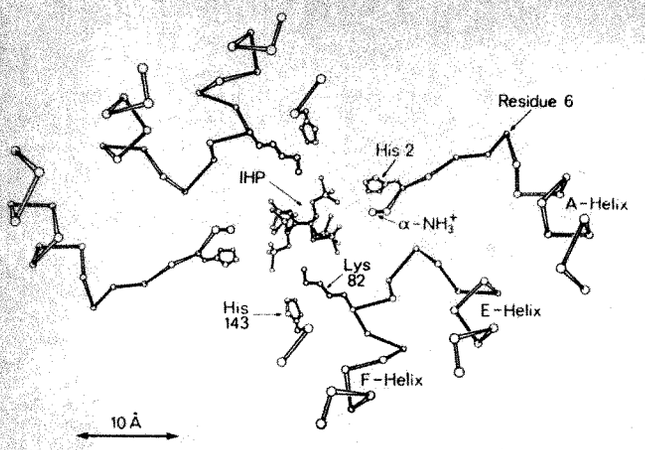

FIG. 4 Binding of IHP to human deoxyhaemoglobin. Note that the conformation of lysine 82 is different from that in Fig. 1. The side chain of asparagine 139 which could form hydrogen bonds with phosphates 1 and 2, lies approximately above that of lysine 82.

82 or of histidine 2. Lack of the former is explained by the fact that the side chain lies in the correct poistion to form salt bridges with phosphates without having to move. The reason for the absence of difference peaks near histidine 2 is not clear because this residue must move with the N-terminus and helix A. The amino groups of asparagines 139β are in positions that allow them to form hydrogen bonds with phosphates 1 and 2.

The DPG difference map showed widespread disturbances to the tertiary structure of the β subunits, and the same are seen in the IHP complex. The movement of the A helix has already been referred to. Weaker difference peaks along helices E and F, and along helix H (not shown in Fig. 2) point to structural disturbances that radiate from the IHP binding site and extend as far as the haem. At our present resolution of 3.5 Å the exact nature and magnitude of these disturbances cannot be determined, but they may be such as to oppose the transition of the tertiary structure from the deoxy to the oxy form, in which case both DPG and IHP should decrease the oxygen affinity of the β subunits in the quaternary deoxy structure.

In summary, the mode of binding of IHP to human deoxyhaemoglobin is similar to that of DPG. There are the same eight basic groups to form salt bridges with the six phosphates of IHP as with the two phosphates and one carboxyl of DPG, but in addition asparagines 139 may form hydrogen bonds with two of the phosphates. Titration of IHP shows that it carries about eight negative charges at *p*H 7.3. Two of the basic groups of the globin, the ϵ amino groups of the lysines, have *p*K's of 10.5 and will therefore be fully charged in the absence of IHP. The four imidazoles and two α amino groups have *p*K's in the neutral range which will rise on combination with IHP, while those of the phosphates will fall. The net effect on the bases, however, clearly dominates, because combination of deoxyhaemoglobin with IHP is accompanied by an uptake of protons[10]. On being bound to crystalline deoxyhaemoglobin grown in concentrated buffers both DPG and IHP displace one inorganic anion from each of the β chains. They both create perturbations to the tertiary structure of the β subunits that extend to the haems and could lower the oxygen affinity by stabilising the quaternary deoxy structure of the tetramer and by constraining the tertiary structure of the β subunits.

In avian erythrocytes inositol 1,3,4,5,6-pentaphosphate (IPP) takes the place of DPG as a regulator of oxygen affinity[5]. The only avian haemoglobin sequence determined so far is that of the chicken[11]. If, as seems likely, IPP takes up the same position in chicken deoxyhaemoglobin as IHP does in human, the number of basic groups facing it would be 12 instead of eight, and would include Val 1, His 2, Lys 82, Arg 135, His 139 and Arg 143. Therefore, the binding energy should be very high indeed.

We thank Dr A. R. Fersht for the titration curve of IHP.

β-2-Microglobulin is part of the HL-A molecule in the lymphocyte membrane

IT has been shown that papain-solubilised HL-A antigens consist of two polypeptide chains, which may be separated under dissociating conditions[1,2]. Peterson *et al.*[3] have shown that β-2-microglobulin (β-2-m) constitutes one of the two polypeptide chains in papain-solubilised HL-A antigens. In these antigens, β-2-m represents a constant small subunit (molecular weight 11,800), whereas a larger subunit (30,000–31,000) carries the allo-antigenic specificity. The studies by Peterson *et al.* do not exclude the possibility that the two subunit structure of HL-A antigens might be a product of the solubilisation process. It has previously been reported[4] that β-2-m, which also occurs in biological fluids[5], is present in high concentrations on the surface of lymphocytes. The

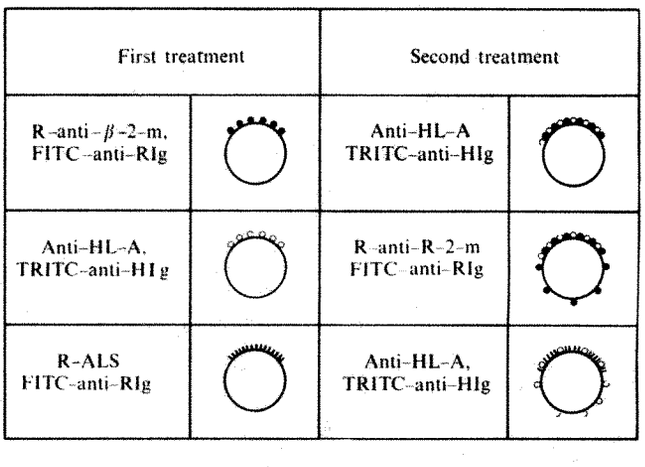

FIG. 1 Diagram of cell membrane antigen aggregation. Lymphocytes were first incubated with one set of antibodies at room temperature followed by incubation for 30 min at 37° C to induce capping of a cell membrane antigen. The cells were then reincubated with other antibodies at 4° C to determine whether the antigenic determinants detected by the second antibody co-capped with the antigen detected by the first antibody. 1, R-anti-β-2-m: Rabbit-anti-human-β-2-microglobulin; 2, R-ALS: Rabbit anti-human lymphocyte serum; 3, Anti-HL-A: Pooled multi-specific anti-HL-A; 4, FITC-anti-RIg: Fluorescein-labelled-swine-anti-rabbit-immunoglobulin; 5, TRITC-anti-HIg: Rhodamine-labelled-goat-anti-human-immunoglobulin".

present study was designed to establish whether β-2-m is part of the intact HL-A molecule in the cell membrane. Experiments were performed in which the blocking of HL-A antigens[6,7], β-2-m and other lymphocyte membrane components were induced by selected antisera. Furthermore, to study the relationship between these cell membrane components and the antigen receptors on lymphocytes, the different antisera were also tested for their ability to induce or inhibit lymphocyte activation *in vitro*. Methodological details are published elsewhere[8].

Anti-human-β-2-m (Dacopatts, 2900 Hellerup, Denmark, Catalogue Code T-072 Lot 023) was prepared in rabbits by immunisation with highly purified β-2-m from urine; the antibody preparation was immunochemically monospecific for β-2-m. Aggregation/blocking of cell membrane antigens was carried out by indirect technique. In 0.2 ml Hanks BSS (Flow Laboratories, Irvine, Scotland), 400,000 human lymphocytes prepared by Ficoll/Isopaque flotation, were first incubated with 0.2 ml of either undiluted anti-β-2-m, two rabbit anti-human lymphocyte sera[9] (ALS) diluted 1:64, or with undiluted multispecific cytotoxic anti-HL-A serum. Preliminary experiments showed that these antiserum concentrations gave optimal cap formation. To potentiate aggregation/capping, the cells were then incubated with 0.2 ml anti-immunoglobulin (FITC-labelled or unlabelled swine anti-rabbit immunoglobulin (Dacopatts 21090 or F2190) or rhodamine-labelled goat anti-human immunoglobulin (Highland, Los Angeles) and warmed to 37° C for 30 min[6,7].

By microcytotoxicity testing[10], undiluted anti-β-2-m induced 60–90% lysis of all human lymphocytes tested; the lysis was reduced to 30–40% after dilution 1:2, and lost upon dilution above 1:8. When the lymphocytes were first incubated with anti-β-2-m and anti-rabbit immunoglobulin, immediately followed by microcytotoxicity typing[10], all detectable HL-A antigens on the tested cells were completely blocked; that is, none of the antigens belonging to three segregant SD series[7] could be detected (Table 1). After incubation in a 1:1 mixture of Medium 199 (Flow Laboratories) and AB serum for 24 h at 37° C, blocked cells again showed a normal typing pattern. Preincubation of the cells with pooled anti-HL-A sera blocked the expression of HL-A antigens, but did not prevent the cells from being lysed by anti-β-2-m (Table 1), thus indicating an excess of β-2-m compared with HL-A in the cell membrane.

Aggregation of cell membrane antigens was also studied by immunofluorescence of double-stained cells. Aggregation was induced during the first staining procedure by warming to 37° C for 30 min; and the second staining step was carried out at 4° C to avoid additional aggregation of membrane components. When cells were first incubated with anti-β-2-m and stained with FITC-labelled anti-rabbit immunoglobulin, followed by incubation with anti-HL-A serum and staining with rhodamine-labelled anti-human immunoglobulin, the red fluorescence of the HL-A antigens was superimposed on the green fluorescence of β-2-m, which showed aggregation into patches and caps in virtually all cells. Figure 1 shows these results in diagrammatic form. (The cells were examined immediately with a Leitz Ortholux microscope equipped with a Ploem-type vertical illuminator, and care was taken to keep the preparations cold). In experiments where the cells after incubation with anti-β-2-m and anti-immunoglobulin were incubated with ALS and fluorescein-labelled anti-rabbit immunoglobulin, marked diffuse fluorescence of the whole cell membrane could be observed.

Thus both microcytotoxicity tests and immunofluorescence demonstrate that anti-β-2-m concomitantly aggregated/blocked β-2-m and HL-A molecules in the cell membrane. This strongly indicates that β-2-m is part of the native HL-A antigens in the cell membrane. By contrast, anti-β-2-m did not coaggregate antigens against which our ALS were directed.

When lymphocytes were preincubated with pooled anti-HL-A sera followed by rhodamine-labelled anti-human immunoglobulin, and then reincubated with anti-β-2-m and double-stained with FITC-labelled anti-rabbit immunoglobulin, immunofluorescence microscopy showed green staining superimposed on red patches and caps, but also diffusely distributed over the rest of the cell membrane, confirming the observations by cytotoxicity tests that there is an excess of β-2-m compared with HL-A antigens in the cell membrane.

When the cells were preincubated with ALS followed by anti-rabbit immunoglobulin, no blocking of the expression of the HL-A antigens could be observed in the microcytotoxicity test (Table 1). When stained with FITC-labelled anti-rabbit immunoglobulin after preincubation with ALS, and reincubated with HL-A antisera followed by rhodamine-labelled anti-human immunoglobulin, the green fluorescence was aggregated into patches and caps in virtually all cells while the red fluorescence showed a diffuse distribution in the cell membrane, and was superimposed on the green patches and caps. The ALS tested, therefore, neither blocked the expression of the HL-A antigens as measured by microcytotoxicity technique nor induced aggregation of HL-A antigens as determined by immunofluorescence.

To test the specificity of the reactions, highly purified β-2-m (supplied by Dr Bengt G. Johansson, Lund) was added to anti-β-2-m, pooled anti-HL-A and ALS. β-2-m (50 μg per 0.2 ml antiserum) abolished blocking and aggregation of HL-A and β-2-m determinants by anti-β-2-m as determined by microcytotoxicity test and fluorescence microscopy. The same amount of β-2-m had no influence on the activity of pooled anti-HL-A sera or ALS.

Studies of lymphocyte transformation *in vitro* were carried out by our micromethod[11]. Results from mixed lymphocyte cultures (MLC) cultured for 5 d in the presence of anti-β-2-m or ALS are shown in Fig. 2. As controls we used partly purified immunoglobulin from rabbits prepared in the same way as the anti-β-2-m antibodies and normal rabbit serum. The results show that anti-β-2-m blocks the MLC reactions (ABm), up to a dilution in normal serum of 1:128. In addition, a very slight but definite mitogenic effect is demonstrated by anti-β-2-m diluted 1:2 (AAm). The ALS shows a much more intense mitogenic effect up to a dilution of 1:32. No definite inhibition of the MLC reactions could be demonstrated by any dilution of the ALS. This is in marked contrast to the results with anti-β-2-m.

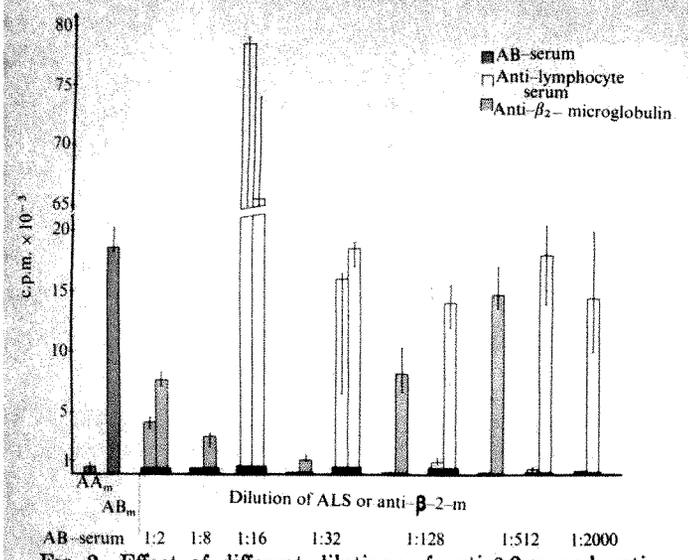

FIG. 2 Effect of different dilutions of anti-β-2-m and anti lymphocyte serum on mixed lymphocyte cultures. 0.15×10^6 responding lymphocytes (from A) were mixed with 0.15×10^6 mitomycin treated stimulating lymphocytes (from either A or B) in the wells of flat bottomed microtitre plates. Each single culture consisted of 0.2 ml Medium 199 supplemented with antibiotics and 20% inactivated normal (AB) or immune serum (diluted in AB-serum). Twenty-four hours before collection, 0.02 ml of 0.05 μCi 2^{-14} C-thymidine was added in physiological saline, the cultures collected on glass fibre filters on day 5, and the degree of proliferation evaluated by liquid scintillation counting. The columns indicate the median of the triplicates, and the brackets show the range. The first column in each pair is the autologous combination (AAm) in test serum, the second is the allogeneic combination (ABm) in test serum. The black areas at the bottom of the columns are the autologous control combinations (AAm) in normal serum. Note the mitogenic affect of both anti-β-2-m and ALS, and the inhibitory effect on MLC exhibited by anti-β-2-m only.

Anti-β-2-m was also found to block completely the stimulation induced by PPD of lymphocytes from a BCG-sensitised individual (10 and 100 μg PPD to 0.15×10^6 lymphocytes in 0.2 ml culture medium; collection on day 4). In parallel experiments, anti-HL-A antibodies directed against the lymphocytes had similar inhibitory activity, while an HL-A antiserum not reactive with the lymphocyte donor and normal AB serum did not affect the response. Addition of 50 μg β-2-m per 0.2 ml antiserum abolished the mitogenic and inhibitory activity of anti-β-2-m, but had no effect on the inhibitory effect of anti-HL-A antisera or the mitogenic effect of ALS.

It has previously been shown[12–14], that antibodies with specificity for HL-A antigens can probably inhibit antigen-induced lymphocyte activation. The results of our present study indicate that anti-β-2-m antibodies also inhibit allogenic lymphocyte stimulation and lymphocyte transformation induced by PPD. Thus, anti-HL-A and anti-β-2-m antibodies which both induce redistribution and removal of HL-A molecules in the cell membrane, inhibit lymphocyte activation *in vitro*. The xenogenic anti-lymphocyte sera tested showed no activity against HL-A antigens or β-2-m, and did not cause detectable inhibition of lymphocyte activation. A slight inhibitory activity in the anti-lymphocyte sera could be overshadowed by the mitogenic activity demonstrated by these sera. There was, however, definitely no inhibition at serum concentrations being 30 to 60 times lower than the optimal concentration for cap formation at the cell surface. By using anti-β-2-m or anti-HL-A sera[13,14], inhibition of lymphocyte activation could be detected at concentrations 30 to 60 times less than those optimal for induction of cap formation. The results with the two anti-lymphocyte sera presented in this study confirm our observations[13,14] that mixed lymphocyte cultures are not necessarily inhibited by all antibodies inducing aggregation of lymphocyte cell membrane components. Inhibitory activity of other anti-lymphocyte sera on lymphocyte transformation has previously been described[15]. This may be due to the presence of anti-β-2-m or other antibodies reacting with the HL-A molecule in these sera.

The efficiency of anti-HL-A and anti-β-2-m sera in inhibiting antigen-induced lymphocyte transformation indicates that both the allo-antigenic subunit and the β-2-m subunit of the HL-A molecule are closely associated with the T lymphocyte receptor. The HL-A molecule may either be part of the T cell receptor, be structurally closely associated with it in the cell membrane, or be functionally associated with lymphocyte activation at a secondary step following antigen binding to the T cell receptor. The convincing homology that has been demonstrated in amino acid sequence between β-2-m and the constant domains of IgG further suggests that β-2-m serves an important effector function in immunological reactions[4].

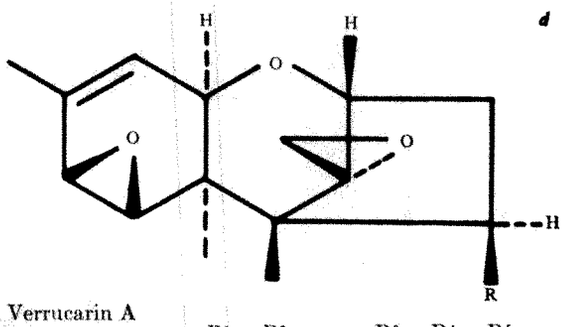
Two classes of inhibitors of peptidyl transferase activity in eukaryotes



THE 12,13-epoxytrichothecenes (Fig. 1) form a group of fungal toxins with a tricyclic trichothecene ring system. (For review, see ref. 1). They have been shown to inhibit protein synthesis in a variety of eukaryotic systems[2] and in particular they block peptidyl transferase activity as determined by the puromycin-fragment reaction[3]. More recent studies have shown however, that the trichothecenes have differential effects on protein synthesis in whole cells[4]. One subgroup containing verrucarin A and T-2 toxin inhibited initiation (I-type), and the other subgroup inhibited elongation/termination (E-type); trichodermin was in the latter group. Here I show that these two classes can also be distinguished in cell-free systems and suggest analogies with the mode of action of the lincosaminide and macrolide inhibitors of protein synthesis in prokaryotes.

It has been observed that the effect of antibiotics on the reaction of puromycin with nascent peptide chains on polyribosomes *in vitro* accurately reflects their effect on trans-

peptidation *in vivo*[5]. The various trichothecene inhibitors were tested using polyribosomes prepared from rat liver, and it was found that the E-type inhibitors, such as trichodermin, inhibit the puromycin reaction, whereas the I-type inhibitors have little or no effect (Table 1). This assay allows the expansion of the E-type subgroup to include crotocin and trichothecin, in addition to trichodermol and trichodermin.

Effect of various trichothecenes on the reaction of puromycin with rat liver polyribosomes and on poly(U)directed phenylalanine incorporation. Polyribosomes from rat liver were prepared as described by Baliga *et al.*[20]. Formation of ^{3}H-peptidyl-puromycin was measured as described previously[6]. Control activity is expressed as pmol of ^{3}H-puromycin incorporated into trichloroacetic acid-precipitable material. ^{14}C-phenylalanine incorporation using yeast extracts was measured as described previously[9]. The average control activity is expressed as total pmol of ^{14}C-phenylalanine incorporated into acid-precipitable, alkali stable material.

The I-type inhibitors inhibit poly(U)-directed phenylalanine incorporation on yeast ribosomes[6]. Various trichothecenes were tested in this system and HT-2 toxin behaved like other I-type inhibitors as it inhibited phenylalanine incorporation at low levels and did not affect peptidyl-puromycin formation even at relatively high levels (Table 1). This suggests that HT-2 toxin will inhibit initiation *in vivo*. It can be seen that the E-type inhibitors do not affect phenylalanine incorporation to the same degree as they inhibit the peptidyl-puromycin reaction. Although crotocol and diacetoxyscirpenol were relatively inactive in both *in vitro* assays, diacetoxyscirpenol inhibits initiation *in vivo*[6].

The fact that the I-type inhibitors (verrucarin A, T-2 toxin, and so on) inhibit the puromycin reaction *in vitro* when using CCA-leu (the fragment reaction)[3] but not the same reaction on polyribosomes is reminiscent of the action of the antibacterial agents lincomycin, certain macrolides such as carbomycin, and the streptogramin A group of antibiotics. These compounds inhibit the puromycin reaction with donors such as CCA-leu in cell-free systems from prokaryotes, but not with nascent peptide chains on polyribosomes; they also seem to inhibit initiation *in vivo*[8]. Further investigation has revealed other similarities between the trichothecenes and the macrolides and lincosaminides.

Surprisingly, although the E-type trichothecenes inhibit elongation *in vivo*, they do not inhibit poly(U)-directed polyphenylalanine synthesis. Similar results have been observed among the macrolides, since erythromycin does not inhibit polyphenylalanine synthesis in a purified *Escherichia coli* system[7], although it inhibits elongation *in vivo*. On the other hand, spiramycin, an I-type macrolide, does inhibit polyphenylalanine synthesis[10].

The macrolide antibiotic erythromycin does not inhibit the fragment reaction although it inhibits the binding of lincomycin, an antibiotic which blocks the fragment reaction on bacterial ribosomes[11]. In addition, erythromycin antagonises the inhibition by lincomycin of the puromycin reaction with $tRNA_f^{met}$ (ref. 12). Lack of inhibition by erythromycin is therefore not the result of an inability to bind to ribosomes under the assay conditions used. I have obtained a similar result with the trichothecenes. Although trichodermin does not inhibit poly(U)-directed phanylalanine incorporation to a large extent, its presence significantly reduces the inhibition produced by I-type inhibitors on yeast ribosomes (Fig. 2*a*). This suggests that trichodermin is bind-

ing to the ribosome and preventing the binding of the other inhibitors. This may indicate partially overlapping binding sites on the ribosome, although other possibilities cannot be excluded, such as the binding at one site producing a conformational change at another site. But the similarity in structure between trichodermin and HT-2 toxin, for example, strongly suggests a common site of binding.

The converse experiment was carried out using varying levels of verrucarin A and trichodermin in a puromycin reaction on rat liver polyribosomes (Fig. 2*b*). The highest concentration of verrucarin A (40 μm) did not antagonise inhibition by trichodermin, whereas the same concentration of verrucarin A inhibits poly(N)-directed polyphenylalanine incorporation by 90%. This could be taken as evidence for binding sites which are not mutually exclusive, but this would conflict with the results of the previous experiment which suggested a common binding site. A more likely possibility is that peptidyl-tRNA prevents the binding of verrucarin A to ribosomes as previously suggested by Cundliffe *et al.*[4]. On stripped ribosomes both E- and I-type inhibitors might bind to mutually overlapping sites. This explains why the I-type inhibitors prevent either initiation or steps shortly after initiation of protein synthesis and not elongation, thereby permitting run-off of polysomes. A similar explanation has been used to explain why the lincosaminides do not inhibit elongation of peptide chains on bacterial polyribosomes[13]. Since verrucarin A does not inhibit the puromycin reaction on salt-washed 80S yeast ribsomes, while trichodermin

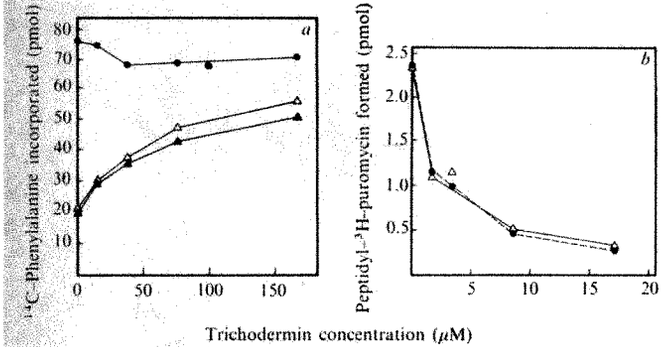

FIG. 2 *a*, Antagonism by trichodermin of the inhibition of poly U-directed phenylalanine incorporation by I-type inhibitors. ^{14}C-phenylalanine incorporation was measured as described previously[6]. Activity is expressed as total pmol of ^{14}C-phenylalanine incorporated into alkali-stable, acid-precipitable material in 30 min. Similar results were obtained using nivalenol (8 μM) and T-2 toxin (2 μM). ▲, Verrucarin A (2.0 μM); △, HT-2 toxin (2.4 μM); ●, control. *b*, Lack of antagonism by verrucarin A of the inhibition of ^{3}H-peptidyl-puromycin formation of trichodermin. ^{3}H-Peptidyl-puromycin was measured as described in Table 1. △, Verrucarin A (40 μM). ●, Control.

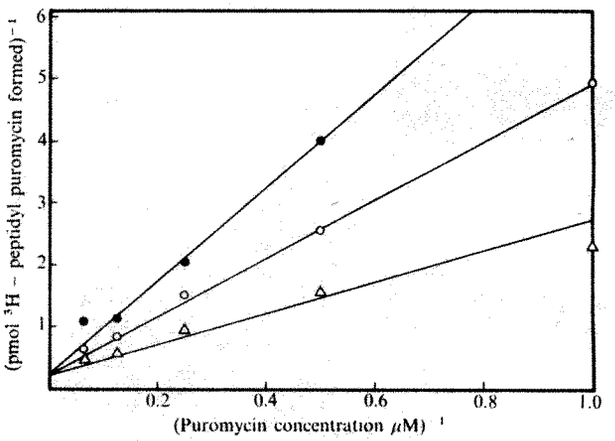

FIG. 3 Competitive inhibition of ^{3}H-peptidyl-puromycin synthesis by trichodermin. Assays were performed as described previously but incubations were carried out for 1 min to provide initial rates. ●, Trichodermin (68 μM); ○, trichodermin (17 μM); △, no trichodermin.

does (unpublished observations), one can probably rule out the involvement of any factor(s) present on unwashed ribosomes which may prevent the binding of verrucarin A.

Further evidence for overlapping sites comes from the fact that a trichodermin resistant strain of *S. cerevisiae*[6] is also resistant to T-2 toxin (100 μg ml^{-1}) and anisomycin (20 μg ml^{-1}). Similarly, bacterial mutants resistant to erythromycin are known to be resistant to lincomycin, spiramycin, and the streptogramin B antibiotics[14].

The nature of the inhibition of the puromycin reaction on rat liver polyribosomes by trichothecenes is of some interest. When plotted on a double reciprocal plot, trichodermin seems to be competitive inhibitor of the puromycin reaction. The K_m for puromycin was 13×10^{-6} M which compares to 8×10^{-6} M previously reported by Pestka[15]. Carbomycin, tylosin, spiramycin, and lincomycin, all I-type macrolides, inhibit binding of CACCA-Phe to prokaryotic ribosomes[16], a model reaction for the interaction of the acceptor aminocyl-tRNA to the peptidyl transferase centre. Trichodermin, trichodermol, and anisomycin inhibit binding of both CACCA-LeuAc and UACCA-Leu to ribosomes, presumably by preventing access of these aminoacyl-tRNA fragments to the donor and acceptor sites of the peptidyl transferase centre[3]. But inhibition of this binding was found to be less than inhibition of the puromycin fragment reaction, which may be due to different experimental conditions in the two assays. The competitive inhibition (elevating the K_m but not changing the V_{max}) which I observe, indicates weaker binding of puromycin and is consistent with blockade of the binding at the acceptor site in the peptidyl transferase centre by tri-

chodermin under conditions more closely resembling protein synthesis (for example, absence of ethanol).

I suggest that the I-type trichothecenes, macrolides, and lincosaminides are similar in their mode of action of protein synthesis inhibition. The basis for the proposed analogy is summarised in Table 2. It fails at one important point for the E-type inhibitors in that the E-type macrolides, such as erythromycin, and the E-type trichothecenes differ in their effects on the peptidyl-puromycin and the puromycin-fragment reactions.

The macrolides which inhibit initiation *in vivo* have been subdivided into two classes based on the size of oligophenylalanine produced in their presence in a poly(U)-directed system[7]; it would be interesting to see if the I-type inhibitors of the trichothecenes can be classified in the same manner. Diacetoxyscirpenol may be a member of a second class of I-type inhibitors because of its anomalous effect on poly(U)-directed polyphenylalanine synthesis.

It has been postulated that the presence of substituents on carbon 15 of the trichothecene ring system may be important in determining whether the toxin will affect elongation or initiation[4]. The assignments of crotocin and trichothecin to the class of E-type inhibitors and HT-2 toxin to the class of I-type inhibitors based on *in vitro* experiments further substantiates this hypothesis. HT-2 and T-2 toxin are substituted at C-15; both crotocin and trichothecin, like other E-type inhibitors, lack a substituent at this position.

This investigation was supported in part by a grant to Dr Julian E. Davies from the National Institutes of Health and by the college of Agricultural and Life Sciences, University of Wisconsin, Madison. I am grateful to Drs Frank Strong, W. O. Godtfredsen, and Charles Tamm for supplying trichothecenes. I thank Dr J. E. Davies for his patience and encouragement; I thank Drs Eric Cundliffe and Michael Cannon for discussions and comments.

Effect of insulin on (Na^+, K^+)-activated adenosine triphosphatase activity in rat muscle sarcolemma

THE existence of (Na^+, K^+)-activated adenosine triphosphatase (ATPase)[1,2] supports a molecular explanation for the active transport of sodium and potassium ions through cell membranes[3].

Other than results from insulin stimulation of membrane-bound ATPases from human lymphocytes[4], no studies have, so far, given any proof of connecting insulin effects on electrolyte transport through cell membranes with the effect on the ATPases. Our observations show an insulin stimulation of sarcolemma-bound ATPase when muscle tissue is incubated with insulin before measuring the enzyme activity on isolated membrane preparations.

Wistar albino rats weighing 170–250 g were fasted for 20–22 h. The rats were killed with a sharp blow to the head and exsanguinated or decapitated when in ether narcosis. In other experiments the animals were anaesthetised with Nembutal sodium (30 mg kg^{-1}, at 30 min intervals) for 1½ h, then bled by cardiac puncture for sugar analysis[5] and decapitated. The leg muscles were excised, transferred to ice-cold 0.9% NaCl, blotted on filter paper and weighed. In the first series, the sarcolemma was isolated according to the method of Severson *et al.*[6], and the membrane preparations incubated with insulin before enzyme assay. In the other experiments, muscle pieces were incubated with insulin (100 mU ml^{-1}) for 15 min in Tyrode's solution[7] before membrane isolation[6]. The membrane pellets from all experiments were resuspended in 0.01 M Tris HCl buffer (*p*H 8.0) approximately five times the original tissue volume (that is, tissue weight) and subjected to two strokes in a Potter-Elvehjem glass homogeniser with a motor-driven Teflon pestle (5,200

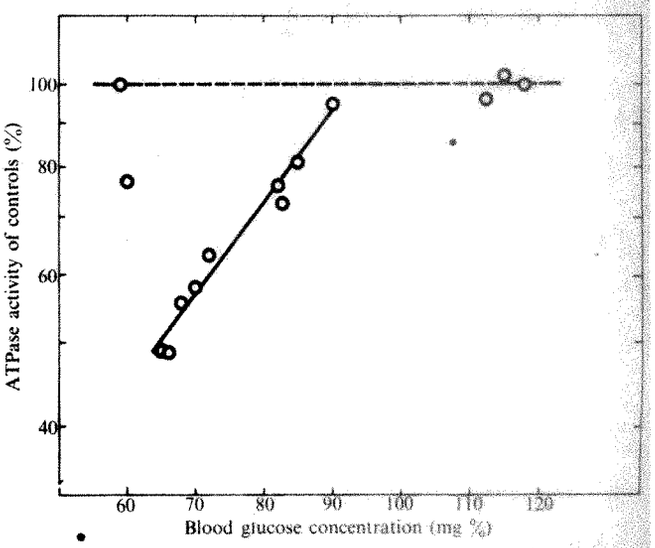

FIG. 1 Semilogarithmic plot of ATPase activity. ●, Variations in specific activities of the controls (%) correlated with blood sugar concentration (mg% whole blood). – – – The specific activities after insulin treatment were taken as 100%; in these experiments only Nembutal-treated rats were used.

TABLE 1 Effect of insulin on isolated muscle sarcolemma ATPase and 5′-nucleotidase activities

Enzyme	No. of experiments	Specific activity ± s.e.m. (μmol P_i per mg protein per min) ×10² Without insulin	With insulin
(Na^+, K^+)-ATPase	15	22.2 ± 1.8	23.3 ± 1.9
5′-nucleotidase	6	2.12 ± 0.15	1.91 ± 0.14

ATPase and 5′-nucleotidase activities at 30° C as liberation of inorganic phosphate from ATP and AMP, respectively. Isolated muscle sarcolemma was preincubated with and without 100 mU ml^{-1} pig insulin at 37° C for 15 min. The membrane preparations were then homogenised in 0.01 M Tris HCl buffer, *p*H 8.0. For the ATPase assay 500 μl of the membranes was mixed with 650 μl Tris HCl buffer, final *p*H 7.6, containing NaCl, KCl, and $MgSO_4$, giving a final concentration of 30, 5, and 0.5 mmol l^{-1}, respectively, after substrate addition. The reaction was started by adding 500 μl 5 mmol l^{-1} ATP and stopped after 2 min by addition of 0.5 ml ice-cold 15% trichloroacetic acid. For the assay of 5′-nucleotidase, 400 μl membrane homogenate and 600 μl Tris HCl buffer, *p*H 8.0, with $MgCl_2$ and AMP to a final concentration of 80 mmol l^{-1}, 0.2 mmol l^{-1}, and 2 mmol l^{-1}, respectively. The reaction was stopped after 10 min. Reaction vessels were centrifuged and the supernatant analysed for phosphate[8]. The precipitate was solubilised in 5 ml 3% deoxycholic acid sodium salt, warmed at 80° C for 5 min and protein content estimated[9] using a bovine serum albumin as standard. Every enzyme sample was run in triplicate.

s.p.m.). The homogenates were used to assay (Na^+, K^+)-activated ATPase and 5′-nucleotidase, as liberation of inorganic phosphate[8] per mg protein[9] per min.

In the third series, non-fasted rats were rendered diabetic by intravenous injection of 55 mg alloxan in a 5% aqueous solution per kg body weight. The severity of diabetes was assessed by measuring the blood glucose[5] 48–72 h after treatment. Blood sugar was sampled at the time the animals were killed. Those having a plasma glucose concentration exceeding 450 mg % were used in the experiments.

Attempts at direct stimulation of the membrane ATPases with insulin did not succeed (Table 1), contrary to the results of Hadden *et al.*[4] Varying the incubation time, temperature, ionic environment, insulin concentration, and preincubation with adrenaline did not alter this. The sample to be examined was compared with a control from the same animal. When muscle cells were preincubated with insulin, ATPase activity was stimulated in the muscle sarcolemma, but the specific activity of the 5′-nucleotidase was unaffected (Table 2).

Although all rats in each series received the same treatment, we obtained great variations in percentage stimulation of ATPase activities. The hormone-stimulated values were quite consistent, but the controls showed great deviations (Table 2). This might indicate that ATPase activity is governed by circulating insulin concentration. If the animals are stressed during handling, there is an increase in blood sugar, followed by an insulin response[10] which, in turn, stimulates ATPase activity. In an attempt to relax the animals, one series of experiments was carried out with the animals anaesthetised with Nembutal. Blood glucose concentration was used as an indication of the circulating insulin level[11].

Figure 1 shows the variations in ATPase activity of the controls, expressed as an exponential function of blood sugar concentration. Insulin stimulation fails when the specific activities approach the maximum level (Fig. 1). The exceptions at the lower sugar concentrations can be explained if one assumes that these low sugar levels result from high circulating insulin concentrations and, consequently, stimulate the ATPase activity, abolishing further stimulation *in vitro*.

The results obtained with muscle tissue from alloxan diabetic rats (Table 2) after *in vitro* insulin treatment show great variation in the stimulation of the ATPase activity, ranging from more than 100% to 0%. When hormone stimulation fails, the specific activity of the control samples is found at the same upper level as those which respond to insulin stimulation. Alloxan in a diabetogenic dose shows a triphasic response, with high insulin secretion in the last phase[12]. Time dependence for reaching nullity of circulating insulin is subjected to great individual variations[13]. Disregarding the irregular data, these results support our hypothesis.

Different types of ATPase activities are recognised within cell membranes. Whether they represent partial activities of the same enzyme system or entirely different enzymes, is still a matter of dispute. The (Na^+, K^+)-activated ATPase has an active site for K^+ outside and an active site for Na^+ inside the cell membrane, and the two ions compete with each other on both sites[3,14].

Omitting K^+ in the enzyme assay resulted in a residual activity of about 8% of controls[15]. This was taken as the criterion for the assumption that the membrane-bound ATPase in question is the (Na^+, K^+)-activated ATPase. Dialysis of sarcolemma preparations against 0.01 M Tris HCl buffer, *p*H 8.0, resulted in a further loss of activities when K^+ was omitted (unpublished data). Omitting both monovalent cations from the enzyme assay resulted in an ATPase activity of 60–70% of that obtained under complete assay conditions, consistent with previous findings[6,16]. We have chosen not to subtract any of these residual or partial activities, because we were able to detect an insulin effect on the ATPase in conditions we consider more 'physiological'.

Our results were obtained with rather high insulin concentrations. The data from a few experiments with physiological hormone concentrations did not show any significant enhancement of the ATPase activity (unpublished data). We interpreted this as a built-in shortage of the *in vitro* system; instead of vascular transport of insulin to the muscle cells, it is distributed within the muscle mass by means of a concentration gradient. When muscle pieces are mechanically divided longitudinally, a leakage of insulin-degrading enzymes from broken cells might occur, which would destroy fractions of the hormone, the degradation being more pronounced, the lower the hormone concentration[17,18]. In addition, insulin might adsorb to glassware. Different species of insulin might also influence the response.

TABLE 2 Effect of insulin on sarcolemma ATPase and 5′-nucleotidase activities after *in vitro* incubation of muscle cells with insulin

Enzyme	Treatment of animals	No. of experiments	Specific activity ± s.e.m. (μmol P_i per mg protein per min) ×10² Without insulin	With insulin
(Na^+, K^+)-ATPase	Ether anaesthesia	15	28.7 ± 2.9	33.5 ± 3.2
(Na^+, K^+)-ATPase	Nembutal	10	21.2 ± 1.5	29.2 ± 0.6
(Na^+, K^+)-ATPase	Alloxan diabetic	5	21.0 ± 3.8	28.0 ± 0.6
5′-nucleotidase	Nembutal	11	2.03 ± 0.13	1.99 ± 0.16

ATPase and 5′-nucleotidase activities assayed at 30° C as liberation of inorganic phosphate from ATP. Except for the alloxan diabetic rats, the animals were fasted for 20–22 h. Small muscle pieces were incubated in cylindrical vessels (1.6 × 10 cm) containing 2.5 ml Tyrode solution (8.0 g NaCl, 0.2 g KCl, 1.0 g $CaCl_2$, 0.05 g $MgCl_2$, 0.05 g NaH_2PO_4, 1.0 g $NaHCO_3$, and 2.0 g glucose diluted to 1 l), flushed with O_2:CO_2 = 95%:5%. Tissue mass per tube was 1.5 g. After temperature equilibrium, 10 μl insulin (1.2 mg ml^{-1}) was added to the incubation medium. Samples and controls were incubated at 37° C for 15 min. The controls and samples were treated equally and isolated simultaneously. The enzyme activities were measured as in Table 1.

It seems reasonable to conclude that insulin stimulates ATPase activity under physiological conditions, as shown indirectly by the variation of the controls as a function of blood sugar concentrations (Fig. 1), and from the fact that the highest control values are not further increased by incubation with high insulin concentrations *in vitro*.

Although this technique is adequate to demonstrate an insulin effect on membrane-bound ATPase activity, a better system must be developed in order to gain an insight into the mechanism of action.

The effect of insulin on stimulation of Na^+ and K^+ transport through muscle cell membranes is long established[19,20] but no attempts to link this effect to an insulin stimulation of the (Na^+, K^+)-activated ATPase have succeeded[2,21]. There might be different reasons for this: the enzyme activity has been assayed with crude cell homogenates in which the insulin effect is masked by gross action of unspecific phosphatases (unpublished results); isolated membrane preparations were exposed to the hormone before the enzyme was assayed without any effects, in agreement with our results, or controls might have been stimulated by insulin release after stress when the animals were killed.

Without any transport data, our experiments led to three conclusions. First, the (Na^+, K^+)-activated ATPase from isolated muscle membranes is not stimulated directly by insulin. Second, incubation of the muscle tissue with insulin before isolation of the membranes resulted in an increased ATPase activity and, third, there seems to be a correlation between blood sugar concentration and the tendency to stimulate ATPase activity *in vitro* by insulin.

We thank Miss Tove Andreassen for technical assistance, and NOVO Laboratorium, Copenhagen for the gift of monocomponent pig insulin.

In vitro suppression of cell mediated autoimmunity in NZB mice

The spontaneous autoimmune disease of NZB mice is characterised by the development of a variety of autoantibodies, particularly those reacting with autologous erythrocytes as demonstrated by a positive direct Coombs test. The onset of autoantibody production coincides with thymic hyperplasia and is followed by splenomegaly and glomerulonephritis[1]. All the tissues contain murine leukaemia virus particles (type C) visible on electron microscopy[2] and Gross antigen is detectable immunologically[3]. This virus is vertically transmitted, yet antibodies have been shown to develop to Gross antigen at the time the direct Coomb's test becomes positive[4]. The role of this virus, if any, in the aetiology of the autoimmune features is still unclear but it has been suggested that this progressive loss of tolerance to Gross antigen is of pathogenetic importance[4,5].

Old surviving mice have a high frequency of lymphomata[6,7]. Many of these are transferable to other mouse strains, but autoimmune phenomena are not associated with these[6,8]. It has not been possible to reliably transmit the disease to other strains with a cell-free filtrate nor indeed with whole cells[9–11] unless sufficient immunosuppression is also used to convert the recipient into an effective chimaera[12]. A depression of cell-mediated immunity to certain extrinsic antigens has been demonstrated in these mice before the manifestation of the autoimmune phenomena[13,14], yet the proportion of θ-positive cells in the spleen was shown to remain essentially undiminished[15,16], although one report does describe a progressive decrease with age[17]. Recently, we have provided evidence which suggests loss of the homeostatic control of autoreactivity with respect to cell mediated immunity: lymphocytes from diseased adult NZB mice were cytotoxic *in vitro* to syngeneic or autochthonous foetal fibroblasts. Cells from young NZB mice did not show this reactivity[18,19]. We here provide evidence that this cytotoxicity depends on the presence of θ-positive, presumably thymus-derived, cells. Furthermore, we were able to show inhibition of the cytotoxic effect of lymphocytes from the Coombs-positive, diseased NZB mice (NZB^+) by non-θ-bearing lymphocytes from young, Coombs negative NZB mice (NZB^-), and from young mice of other strains.

A modification of the microcytotoxicity assay of Takasugi and Klein[20] was used as previously described[18]. Test fibroblasts were cultured in Falcon microtest plates at a concentration of 100 cells per well and 24 h later, splenic lymphocytes purified on a Ficoll/Isopaque gradient[21] were added.

In these conditions, lymphocytes from NZB^+ mice were cytotoxic to syngeneic or autochthonous foetal NZB fibro-

blasts as is seen in Table 1. As our tissue culture system used heat-inactivated foetal calf serum in the culture medium, this phenomenon was most likely the result of cell mediated autoreactivity. In our previous experiments, no significant toxicity was demonstrable against fibroblasts from neonatal or adult BALB/c and CBA mice[18]. The ratios of lymphocytes to fibroblasts were varied from 1:10 to 1:2,000. The dose response curve obtained, showed that near maximal killing was achieved with a cell number ratio of 1:200 (ref. 18). In keeping with the methodology developed by Hellstrom[22], experiments were carried out using a ratio of one fibroblast to 2,000 lymphocytes.

The cellular origin of the NZB-killer activity was assessed by testing for the possible involvement of θ-bearing thymus derived cells. Lymphocytes from NZB$^+$ mice were treated with anti-θ serum and complement as described elsewhere[23]. The potency of this antiserum was verified by its capacity to interfere with the *in vitro* immune response to a T-cell dependent antigen (sheep erythrocytes) but not to a T-cell independent antigen (polymerised flagellin from *Salmonella adelaide* strain 1338). The source of complement was guinea pig serum previously absorbed with agarose for 30 min at 4° C, according to the method of Cohen and Schlesinger[24]. Such serum was free of non-specific cytotoxicity and had no effect on the potency of 'killer' cells from NZB$^+$ mice. Results from a representative experiment shown in Table 1 indicate that the cells involved in the 'self' killing mechanisms bear the θ antigen. The result of diluting the anti-θ antiserum can be seen in Table 2. It is only effective in the presence of complement. Cohen[25] has previously described

TABLE 3 The effect of the addition of lymphocytes from young animals on the cytotoxic ability of cells from diseased NZB mice on their isogeneic fibroblasts.

the development *in vitro* of cell mediated autoimmunity. The responsible cells here too seem to be of thymic origin.

We have previously reported that the *in vitro* killing of NZB fibroblasts by NZB$^+$ lymphocytes may not be inhibited by serum from young NZB$^-$ mice[26]. It seems that the mechanisms which must prevent *in vivo* autoreactivity in the clinically normal, NZB$^-$ mouse are mediated by either serum factors too weak to be detected *in vitro* or by direct cellular control. To try and re-establish control over the autoimmune response *in vitro*, lymphocytes from NZB$^+$ mice were mixed with cells from 4-week-old mice before being added to the fibroblasts. Table 3 demonstrates that substitution of even 10% of cells from NZB$^-$ mice significantly suppressed the autoreactivity of lymphocytes from diseased NZB mice. This suppression effect was also demonstrable with cells from both BALB/c and CBA/HI strains. In each case, the effect of NZB$^-$ cells alone was taken as the control but each experiment must be considered individually as different lymphocytes have a variable stimulating effect on the growth of the fibroblasts present. It is therefore difficult to compare directly the relative efficacies of different cell types in their capacity as suppressor cells in this system. One may argue that inhibition of fibroblast killing by cells from clinically normal mice could have been due to a dilution effect on the killer cells. It is also possible that NZB$^-$ cells added to

TABLE 4 The effect of pretreating young NZB lymphocytes with anti-θ antiserum and complement on the inhibition of the autoimmune response.

§ Killed by heating at 56° for 30 min

the autoreactive lymphocytes have acted as alternative targets and may thereby have competed with target fibroblasts for killer cells.

These suggestions seem untenable for the following reasons. First, the reduction in total number of self reactive cells from 200×10^3 to 180×10^3 or even 20×10^3 had little effect on reducing fibroblast killing[18] indicating that there was a gross excess of 'killer' cells when 200×10^3 lymphoid cells from NZB$^+$ mice were added to the 100 fibroblasts in a single well. Second, heat killed lymphocytes no longer inhibited the autoreactivity of NZB$^+$ cells (Table 4).

If the NZB$^-$ cells responsible for the suppression phenomenon were theta-bearing thymus-derived cells, suppression of autoreactivity should no longer be demonstrable after treatment of these cells with anti-theta serum and complement. As seen in Table 4, however, preincubation of young NZB cells with these reagents failed to abolish the *in vitro* suppressive effect. We tentatively suggest, therefore, that the observed suppression of self reactivity is mediated by θ negative bone-marrow derived B cells rather than by thymus-derived T cells. This is in accord with the similar finding of Phillips and Wegmann[27] on tetraparental mice. The possibility is not ruled out, however, that T cells with a low density of the θ surface marker may have escaped the cytotoxic action of anti-θ serum and complement.

Suppression of cell-mediated immunity by humoral factors

is now well known in similar experimental situations to the above. We have suggested earlier on experimental grounds that blocking of immunocompetent cells by antigen–antibody complexes could account for mechanisms of self tolerance[28]. As discussed elsewhere, immunocompetent cells could conceivably become inactivated *in vivo* by antigen–antibody complexes in solution or when attached to the surface of macrophages[29]. Depending on the configuration of a complex (as determined by the relative amounts of complexed antigen and antibody) a matrix of closely spaced free antigenic determinants of identical specificity would provide the optimal conditions for lymphocyte inactivation. In the case of tissue fixed complexes *in vivo*, blocking activity in serum may be minimal or totally absent and this could account for our failure to demonstrate such activity in the serum of NZB$^-$ mice[26]. Furthermore, inhibition *in vitro* of self reactivity by the addition of small numbers of lymphocytes from healthy animals could be due to the release of B cell derived 'auto-antibody' becoming complexed with a fibroblast derived 'self' antigen. These complexes would readily interact directly with immunocompetent effector cells by blocking their reactivity. A key question pertains to the mechanisms responsible for the breakdown of self tolerance in NZB mice as well as to the nature of the relevant antigen in this case. Although our work to date fails to provide information on these points, it opens a new experimental approach to the investigation of self tolerance and its homeostatic control.

Intracellular J chain in mouse plasmacytomas secreting IgA, IgM and IgG

THE final step in assembly of IgA and IgM is the polymerisation of intracellular monomeric (H_2L_2) subunits. This event takes place just before, or at the time of secretion[1–7], and involves the incorporation of J chain[8,9] into IgM[10] and polymeric, but not monomeric IgA[10–11]. An unanswered question is whether J chain travels through the membranous elements of the cell, as do the other immunoglobulin subunits[12]. As a prelude to answering this, we have demonstrated intracellular J chain in polymer-secreting mouse myeloma cells. In addition, the postulation of an intraclonal switch from IgM to IgG in B-lymphocytes[13] prompted us to look for, and find, J chain in cells which secrete IgG.

To detect intracellular J chain, mouse myeloma cells were grown *in vitro* in the presence of radioactive leucine[1]. The cells were lysed either with 1% (w/v) Nonidet P40 or 1% (w/v) sodium deoxycholate in the presence or absence of 0.1 M iodoacetamide. Following centrifugation (30,000*g*, 40 min), a rabbit antiserum reactive with free, but not bound, J chain (R.M.E.P., unpublished) was added to the cell lysate, and complexes of radioactive J chain and the rabbit antibody were precipitated with goat anti-rabbit IgG as previously described[1]. The antibody–antigen precipitates were washed, reduced and alkylated and electrophoresed in alkaline urea polyacrylamide gels[10,14], and the amount of radioactivity in J chain was measured as the total found in the J chain peak.

Initial experiments were done with a tissue culture-adapted cell line of MOPC 315 which produces IgA and which was found to secrete 70% of the myeloma protein in dimer form; the remaining myeloma protein consisted of monomer and higher polymers in approximately equal amounts. With this cell line, similar yields of radioactivity in intracellular J chain were obtained whichever of the methods outlined above was used for lysing the cells.

The results of a typical experiment are presented in Fig. 1. When the total radioactive cell lysate was electrophoresed in an alkaline urea gel (Fig. 1*a*) there was no discrete peak of J chain. The presence of intracellular J chain could only be demonstrated in the precipitate formed with the specific anti-J chain reagent (Fig. 1*b*). Electrophoresis of unlabelled cell lysates of MOPC 315 myeloma cells followed by staining of the polyacrylamide gel, however, has been reported to reveal a prominent band in the J chain position[15]. In similar experiments using 6% (w/v) alkaline urea polyacrylamide gels we were unable to demonstrate J chain in MOPC 315 myeloma cell lysates, and we would therefore conclude that the reported prominent J chain band[15] is contaminated by other proteins.

To be certain that the peak of radioactivity in the J chain position (Fig. 1*b*) is authentic, and not the result of another cellular protein with similar electrophoretic properties, the radioactive cell lysate was reacted with a sample of anti-J chain antiserum which had been previously absorbed with a highly purified preparation of mouse J chain[16]. The re-

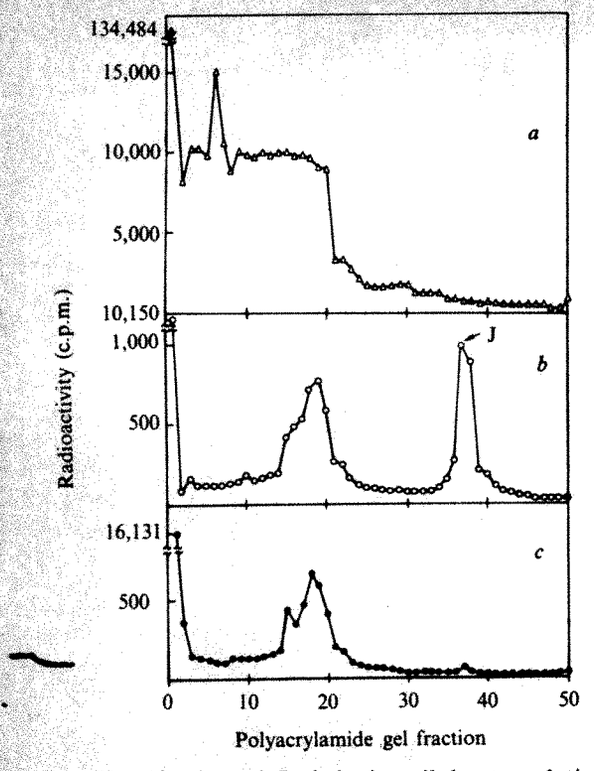

FIG. 1 Identification of J chain in cell lysates of tissue culture-adapted MOPC 315 mouse myeloma cells. Analysis by polyacrylamide gel electrophoresis. Myeloma cell suspensions at 2×10^7 cells ml^{-1} were incubated for 2 h in Eagle's medium containing 0.2 mCi of L- 4,5-^{3}H-leucine (51 Ci $mmole^{-1}$) ml^{-6}. The cells were collected by centrifugation, washed once with tissue culture medium and lysed in 0.075 M NaCl–0.075 M Tris–HCl, *p*H 8.0 containing 1% (w/v) sodium deoxycholate, 0.1 M iodoacetamide and DNAse (50 μg ml^{-1}). After standing at 37° C for 10 min, the cell lysates were centrifuged at 30,000*g* for 40 min and the supernatants were reserved for analysis on alkaline–urea 6% (w/v) polyacrylamide gels[10,14]. Before electrophoresis of the total unfractionated cell lysate, the material was dialysed against 8 mM Tris–25 mM glycine, *p*H 8.7. Radioactive J chain in the cell lysate was isolated by precipitation of soluble complexes formed between rabbit anti-mouse J chain and intracellular J chain with goat anti-rabbit immunoglobulin. As a control precipitation, a sample of the rabbit anti-mouse J chain was first absorbed with an excess of purified J chains[16] and then added to the radioactive cell lysate for precipitation with goat anti-rabbit immunoglobulin. Antibody–antigen precipitates were washed four times with phosphate-buffered saline containing 1% (w/v) Nonidet P-40, once with 8 mM Tris–25 mM glycine, *p*H 8.7, and then dissolved in 9 M urea–10 mM dithiothreitol by heating for 2 h at 56° C. Samples were then applied to alkaline–urea (6% (w/v)) polyacrylamide gels. The gels were sliced, dissolved and counted[10], and fractions are numbered from the negative (top) to the positive electrode. *a*, Total cell lysate; *b*, radioactive protein in the cell lysate precipitated by the rabbit anti-(mouse J chain) antiserum; *c*, radioactive protein in the cell lysate precipitated with the rabbit anti-mouse J chain antiserum which had been previously absorbed with purified mouse J chain.

sulting antibody–antigen precipitate between rabbit IgG and goat anti-rabbit IgG no longer contained radioactive J chain (Fig. 1*c*), thereby unequivocally confirming the original identification (Fig. 1*b*). The problem of non-specific contamination of the antibody–antigen precipitate is overcome by taking advantage of the unique electrophoretic mobility of J chain. The amount of radioactivity coprecipitated by absorbed and non-absorbed anti-mouse J chain is essentially the same, and only when the electrophoretic analysis is done can J chain be identified and quantitated.

The absence of a covalent linkage between intracellular J chain and the intracellular monomer precursor of secreted polymer[7,10] was confirmed with the tissue culture form of MOPC 315 myeloma cells, taking advantage of the specificity of the myeloma protein for 2,4-dinitrophenol. Cells (2×10^7 ml^{-1}) were labelled for 1 h with ^{3}H-leucine (59 Ci $mmol^{-1}$, 0.2 mCi ml^{-1}), and the resulting cell lysate (1% w/v Nonidet P-40, 0.1 M iodoacetamide) was filtered through a column of ε-N-2,4 dinitrophenyl-lysyl-sepharose[17]. The eluate was examined for free J chain by precipitation with the specific antiserum. The intracellular monomeric IgA was eluted from the column with 0.1 M DNP-glycine, reduced (10 mM dithiothreitol) and then electrophoresed in alkaline urea polyacrylamide gels to determine the presence or absence of associated J chains. Free J chain was found in the filtrate from the column and accounted for 1.5×10^{-2}% of the total radioactivity precipitated by 10% (w/v) trichloracetic acid; there was no detectable J chain associated with intracellular myeloma protein, although 10^5 c.p.m. were applied to the polyacrylamide gel.

Having identified J chain in the tissue culture-adapted MOPC 315 myeloma cell line, we then examined a variety of other tumour lines using similar methodology. The results are summarised in Table 1. Not unexpectedly, J chain was detected in cells secreting polymeric IgM (MOPC 104E) and IgA (MOPC 315 and 5647). More interesting was the finding of comparable amounts of J chain within myeloma cells secreting IgG_1 (MOPC 21 and MOPC 70E) and IgG_{2a} (Adj PC5 and 5563). In all cell lysates where a positive identification of J chain was made, there was no characteristic peak on polyacrylamide gel when the rabbit antiserum was absorbed with purified mouse J chain before the formation of the antibody–antigen precipitates with goat anti-rabbit immunoglobulin. We are therefore confident of our identification of J chain in IgG-secreting plasma cells. Relatively less J chain was present in a myeloma which secretes half molecules (HL) of an IgA (MOPC 47A) containing heavy chains of shorter than normal length[18,19]. No J chain could be detected in a tumour line which secretes only monomer (H_2L_2) species of IgA (MPC1). This is further evidence that the peak identified on alkaline-urea polyacrylamide gels is authentic J chain, because if this component were a polypeptide which fortuitously cross-reacted with J chain, its presence would be predicted in all myelomas.

The finding of J chain in IgG-secreting myeloma cells raises the question of whether J chain is restricted to cells of lymphoid origin. We therefore labelled a permanent cell line of mouse L cells and looked for J chain, as detailed in the

TABLE 1 Presence of J chain in mouse myeloma cells.

Tumour	Product	J chain (% total radioactivity $\times 10^{-2}$)
MOPC 104E	IgM, free L	3.29
MOPC 315	IgA (monomer and polymer)	2.81
5647	IgA (monomer and polymer)	1.03
MPC 1	IgA (monomer only)	Not detected
MOPC 47A	IgA (HL half molecule)	0.26
MOPC 21	IgG_1	1.35
MOPC 70E	Free L (K), traces of IgG_1	3.17
Adj PC5	IgG_{2a}	2.45
5563	IgG_{2a}	1.32

Myeloma cell suspensions were prepared from solid tumours, incubated for 2 h with radioactive leucine and cell lysates were prepared as indicated in the legend to Fig. 1. Total radioactivity in protein was measured by precipitation with 10% (w/v) trichloroacetic acid. Samples containing 2×10^7–6×10^7 c.p.m. were reacted with the rabbit antimouse J chain antiserum and goat anti-rabbit immunoglobulin, and the precipitates were analysed on alkaline–urea–polyacrylamide gels as described in the legend to Fig. 1. The radioactivity in J chain was obtained by summing the counts found in the position on the gel characteristic for J chain. This amount is expressed as % of the total trichloroacetic acid-precipitable radioactivity in the cell lysate. Verification of identity was obtained in all cases by electrophoresis of precipitates made using a sample of rabbit anti-mouse J chain previously absorbed with purified mouse J chain (see text and legend to Fig. 1).

legend to Fig. 1. J chain could not be detected in radioactive lysate samples containing up to 6×10^7 c.p.m. Although more non-lymphoid cells need to be examined, nonetheless the tentative conclusion is that J chain is not a ubiquitous cellular constituent and may be confined to cells of lymphoid origin.

What is the fate of J chain synthesised by IgG-secreting cells? One possibility is intracellular degradation and another secretion. The latter is more easily tested. Myeloma cells secreting IgM (MOPC 104E), IgA (MOPC 315), IgG_1 (MOPC 21) and IgG_{2a} (5563 and Adj PC5) were incubated with radioactive leucine and allowed to secrete for a period of 5 h. Culture supernatants containing 2×10^7 c.p.m. in trichloroacetic acid-precipitable radioactivity were tested for the presence of free J chain using the specific rabbit antiserum as already described. In all cases tested free J chain was absent. This makes it more likely that it is degraded following synthesis by IgG-secreting cells. This would be compatible with the absence of covalent and non-covalent interaction between intracellular immunoglobulin and J chain[7,10], and the fact that only at the subcellular site where polymerisation takes place is J chain incorporated into polymer molecules[10,11]. As polymerisation takes place just before, or at the time of, secretion[1-7], it is reasonable to suggest that newly synthesised J chain follows the same intracellular route irrespective of the class of immunoglobulin secreted. If J chain is degraded in IgG-secreting cells, this probably occurs at the same subcellular site as polymerisation.

The failure of the IgA-secreting tumour line MPC1 to secrete polymeric molecules is not entirely attributable to the absence of J chain. The reason for this assertion is that secreted IgA monomers of MOPC 315 can be polymerised *in vitro* when J chain and a disulphide interchange enzyme are supplied[16]. In identical conditions, the secreted monomeric IgA of MPC1 is not polymerised (R.M.E.P., and E. Della Corte, unpublished). A likely explanation would be a structural alteration in the heavy chain, perhaps at the site involved in linkage to the J chain. The secreted HL subunits of MOPC 47A were also unable to form polymers *in vitro* when supplied with J chain and the disulphide interchange enzyme (R.M.E.P., and E. Della Corte, unpublished). Extensive deletions are known to be present in the heavy chain of this tumour line[18,19]. The presence or absence of intracellular J chain, together with the potential for secreted immunoglobulin to be polymerised *in vitro*, should form the basis of a valuable approach for analysis of myeloma variants secreting IgA and IgM.

The MOPC 70E tumour line secretes traces of IgG_1, but the major secretory product of the cell is light chain. In this situation of suppressed heavy chain synthesis, however, intracellular J chain was demonstrated, indicating that the genes for heavy chains and J chains are not coordinately controlled.

What is the significance of J chain present in myeloma cells secreting IgG? While other interpretations must be considered, for example that the cells studied are neoplastic, it is possible to speculate that intracellular J chain in IgG-secreting cells represents a relic from previous commitment to IgM synthesis, which would also allow the same progenitor cell line to switch from IgG to IgA synthesis. Such a developmental succession of immunoglobulin class expression has already been postulated[13].

We would like to thank Dr Michael Potter of the National Institutes of Heatlh, Bethesda, Maryland, for supplying the mouse myeloma tumours, Dr A. R. Williamson for supplying MOPC 315, Dr M. Esteban of the Division of Virology, National Institute for Medical Research, London, for supplying the permanent cell line of mouse L cells and Iain Hunter for indispensable assistance. H.K. was supported by a United States Public Health Service grant while on leave of absence from the Institute for Cancer Research, Philadelphia, Pennsylvania.

Expression of polyoma-induced antigens in low malignant hybrids derived from fusion of a polyoma-induced tumour with a fibroblast line

HARRIS *et al.*[1] have shown that hybrid cells (A9/SEWA) derived from fusion of cells of polyoma-induced sarcoma (SEWA) and an aneuploid long-established fibroblast line (of L origin), A9, had low tumorigenicity (Table 1)[2]. They have also shown[3] that the polyoma-induced transplantation antigen (PTA) was present in low tumorigenic hybrids of SEWA/T6 T6. To investigate the relationship between malignancy and cell surface modifications, we analysed, in this system, the polyoma-specific surface antigen revealed by immunofluorescence[4] concurrently with other characteristics of these cells, such as karyotype, transplantability and the presence of T antigen.

Antigen T was demonstrated by immunofluorescence on fixed cells as previously described[5,6]. Two positive antisera were used. The counts were done on 10^3 cells for three independent experiments. The parental SEWA cells and the A9/SEWA hybrid were both strongly positive. The parental A9 strain was negative (Table 2).

Surface antigen was studied on living cells using the technique we have previously described[4]. Five hundred cells were counted and two repeat counts performed for each experiment. The antisera were produced in A.SW mice injected with 10^7 PFU polyoma virus once a week for 3 weeks. After an interval of 1 week, the mice were challenged with 10^5 SEWA cells injected intraperitoneally. The sera collected from the tumour-free mice, 2 weeks later, were tested by immunofluorescence using SEWA cells as the positive control and A9 and A.SW mouse kidney cells as negative controls. Positive results were also obtained when these sera were tested against cells of a cell line (C3H Py Broc.) that had been

transformed *in vitro* by polyoma virus. The results, summarised in Table 2, show that the hybrid does carry the polyoma-specific membrane antigen in very similar proportions (about 80%) whatever the passage level.

TABLE 2 Polyoma antigens

Cells	A9	SEWA	A9/SEWA 8th passage*	A9/SEWA about 10th passage*	A9/SEWA about 40th passage*	A9/SEWA 43rd passage*
T antigen % of positive cells	0	60 ± 10		30 ± 10	20 ± 10	
Polyoma-specific surface antigen 11% of positive cells	0.4	88 ± 5	82 ± 5			88 ± 5

* Average results of four experiments done on subcultures about tenth or fortieth serial passage after the receipt of the hybrid at Marseilles.

Experiments with antiserum absorption gave results which did not differ significantly between the parent lines and the hybrids. The following technique was used in these antiserum absorption experiments. The limiting dilution (1/320) of the anti S-polyoma serum was first determined using a

TABLE 3 Absorption of antiserum by ascitic SEWA and A9/SEWA cells

Cell line	Number of cells ($\times 10^7$) used for absorption	% positive cells
	0.5	80
	1	80
SEWA	2.5	30

	10	5

Anti S-Polyoma serum at 1/320 dilution was absorbed by contact with the cells for 1h at 37°C and overnight at 4°C. The serum was then retested on the target cells (SEWA and A9/SEWA).

1/10 dilution of fluorescein-labelled anti-mouse immunoglobulin. The absorption was then carried out by contact of the serum at 1/320 with the cells for 1 h at 37° C and overnight

TABLE 4 Surface histocompatibility antigens measured by immunofluorescence

Cell antigens	A9	SEWA	A9/SEWA
H-2^k*	45%	2%	35%
H-2^s*	4%	30%	23%

* Once a week A.SW mice were injected intraperitoneally with 10^6 C3H mouse spleen cells for 3 consecutive weeks. These spleen cells were prepared for injection as follows: the spleen was removed and the cells scraped off with a file. The resulting cell suspension, which contained many red blood cells was first washed in PBS free of Ca^{++} and Mg^{++} by centrifuging at 200*g* for 5 min. After treatment by hypotonic shock, the cells were collected by a second centrifugation. The same operation was performed with C3H mice injected with spleen cells of A.SW mice; sera were used at 1/30 dilution.

at 4° C. The serum was then retested with the target cells (SEWA cells in ascitic form). Absorption with 5×10^7 SEWA cells in ascitic form ml^{-1} and 2.5×10^7 A9/SEWA cells ml^{-1} was necessary to obtain identical extinctions (Table 3). When the cell size and the fact that about 30% of the cells in the ascitic form of the SEWA tumour are not tumour cells (for example the macrophages and endothelial cells) are considered, this difference cannot be regarded as significant.

TABLE 5 Immunogenicity

A.SW pretreated with	Total N° of inoculated cells	Takes in A.SW mice 20 d after challenge
10^6 PFU polyoma	—	2/11
A9/SEWA*	3×10^6	3/22
UV irradiated SEWA (3,000 erg mm^{-2})	3×10^6	2/6
A9	3×10^6	5/5
Control	—	14/15

* Average results of three experiments done on subcultures about thirtieth and sixtieth serial passage after receipt of hybrid at Marseilles.
Growth in 2 month old A.SW mice of SEWA in ascitic form after inoculation of various agents once a week for 3 week interval of 2 week and then a challenge I/P injection of 1×10^3 SEWA cells.

The results of testing for H-2 antigens are shown in Table 4 and the ability of various test cells to induce a rejection reaction of TATA-positive SEWA cells in syngeneic A.SW mice are shown in Table 5.

The karyotype study, which mainly took into account the evolution of the mode and the presence of markers with respect to the passage level of the cell lines, was carried out both for the hybrid and parental strains, and is summarised by the histogram in Fig. 1.

The presence of these antigens indicates that the viral genome is expressed in the hybrid cells. We have demonstrated previously that at least half of the polyoma genome necessary for replication is involved in the coding for the expression of T and S antigen[7,8] and one fifth for the expression of TATA. It is also clear that the introduction of a fibroblast genome represses malignant behaviour, as shown previously[9] but does not interfere with the polyoma-specific antigen expression of the transformed cells. In view of the fact that only certain cells can be transformed by polyoma virus, the genetic or the epigenetic constitution of the target cell is obviously decisive for its competence to behave as

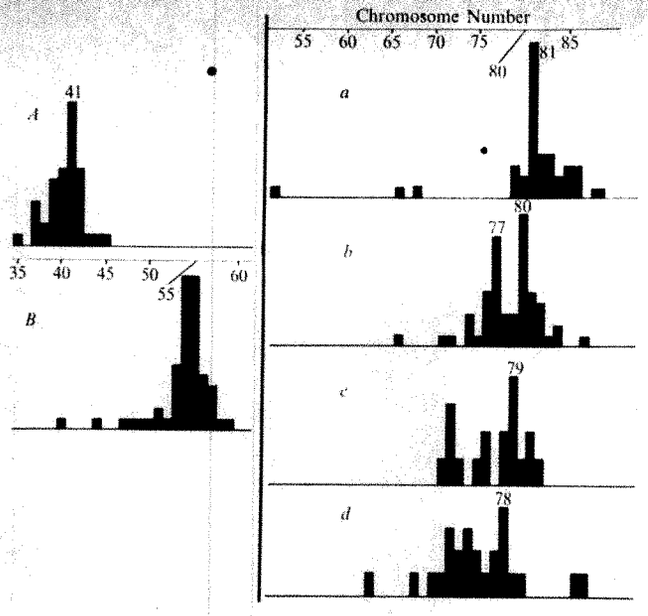

FIG. 1 Karotype analysis of hybrid and parental strains. *A*, SEWA; *B*, A19; *a* A9/SEWA hybrid, third passage; *b*, twenty-eighth passage; *c*, seventieth passage; *d*, 118th passage.

a malignant cell after the covalent integration of the viral genome. The role of the cellular genome is also suggested by the experiments on reversion[10], showing that rearrangement of the genetic material may suppress the expression of transformed and/or neoplastic properties, in spite of the continued presence of the viral genome. The same conclusion is reinforced by our findings on hybrid cells. Obviously the genome of at least certain fibroblasts will inhibit tumour growth, in spite of the continued presence of the virally determined antigens. Although these antigens may be necessary for the malignant behaviour of the polyoma transformed cell, with the appropriate genetic or epigenetic constitution, it will follow from this reasoning that this is not necessarily sufficient and other modifying factors may play a decisive role for the realisation of the virally determined neoplastic potential.

We thank Jacqueline Simonetti and Anne-Marie Bernard for technical assistance, and Dr Fogel of the Weizmann Institute for providing one of the anti-T antisera.

Lipopolysaccharides inhibit lymphosarcoma cells of bone marrow origin

BACTERIAL lipopolysaccharides (LPS) stimulate DNA synthesis specifically in B (thymus-independent) lymphocytes[1–3], increase immunoglobulin synthesis and secretion in B cells[5], and stimulate the immune response of antibody production to various antigens in the apparent absence of T (thymus-dependent) lymphocytes[4,6–8]. Recently a mouse B lymphosarcoma, PU-5-1, has been described which has surface immunoglobulin[9], and produces a small amount of immunoglobulin (R. Asofsky, unpublished). Cells of this tumour were adapted to culture and tested for the LPS stimulation of immunoglobulin secretion. Surprisingly, growth of the tumour cells was inhibited by LPS, although there was no effect on mouse myelomas or T lymphomas. Inhibition also occurred with an Abelson leukaemia virus induced tumour believed to represent a B lymphoma[10] or immature myelomonocytic neoplasm[11]. No effect was observed on the growth rate of a number of human B cell lines tested. LPS is not cytotoxic for the tumour cells: growth resumes when it is removed. Incorporation of precursors into DNA is inhibited before RNA and protein synthesis is affected. The active com-

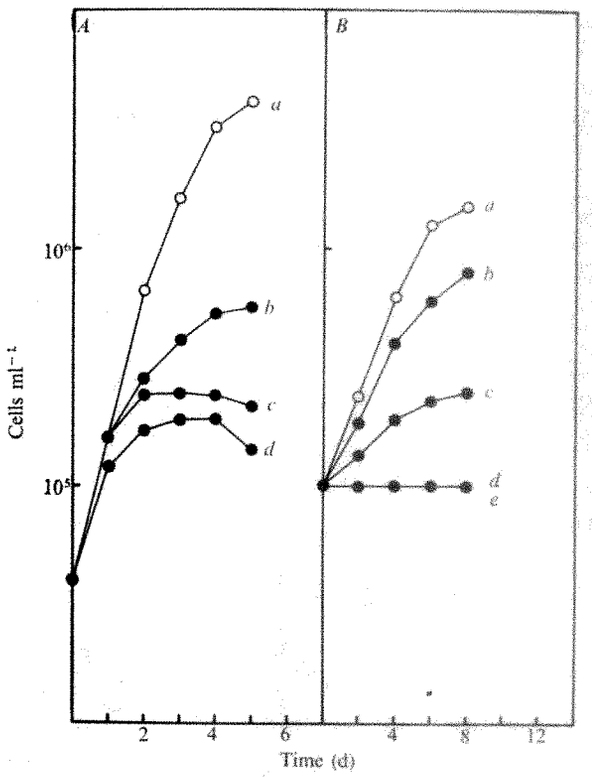

FIG. 1 Growth inhibition by LPS. *A*, RAW 8 cell line was adapted to culture from the second transplanted generation of a BALB/c tumour originating from infection of spleen cells *in vitro* with Abelson leukaemia virus[30] (in preparation). The cells grow as round floating cells in Dulbecco modified Eagle's medium containing 10% foetal calf serum in Petri dishes[16]. LPS (*S. typhosa* W 0901, Difco Laboratories, Detroit) was dissolved in phosphate buffer, *p*H 8.0, at 10 mg ml^{-1}, boiled for 60 min, and stored frozen until use. Cultures were innoculated at 0.4×10^5 ml^{-1} with *a*, 0; *b*, 1; *c*, 5 or, *d*, 50 μg ml^{-1} as shown. Viable cell counts were made daily. *B*, PU-5-1 is a spontaneous lymphosarcoma from a germ-free BALB/c mouse with immunoglobulin μ and κ determinants on its surface[9] (obtained from R. Asofsky, N.I.H., Bethesda, Maryland). The tumour was adapted to culture at generation 35 and grown in RPMI-1640 medium with 10% horse serum as above. Cultures were initiated at 1×10^5 cells ml^{-1} with, *a*, 0; *b*, 1; *c*, 5; *d*, 20 or *e*, 50 μg ml^{-1} LPS as shown.

C1498	Myeloid leukaemia	UM-37	

Cell lines were tested for growth inhibition by LPS as in Fig. 1. Cultures of cell lines listed as Resistant contained more than 50% of the number of cells in control cultures when incubated 4–8 d with 100 μg ml^{-1} LPS. P815-X2 was obtained in culture from D. Grausz, University of California at San Diego; WEHI-22.1 from A. Harris, Walter and Eliza Hall Institute, Melbourne; GM-86 from Institute for Medical Research, Camden, New Jersey. The other mouse cell lines are listed in ref. 16. Marmoset and human cell lines were obtained through the courtesy of R. Lerner[28], Scripps Clinic and Research Foundation, La Jolla, California; G. Moore[17], Denver General Hospital, Denver; A. Bloom[29], University of Michigan, Ann Arbor; and G. Klein, Institute of Tumor Biology, Stockholm. UM-37 was derived from a patient with myeloma. The primate lines were grown in RPMI-1640 medium containing 10% foetal calf serum in Petri dishes.

ponent of LPS seems to be the lipid A, as shown for its pyrogenic[12], mitogenic[8,13–15], and adjuvant[8,13] properties.

At 1–50 μg ml^{-1}, LPS from *Salmonella typhosa* inhibited the growth of RAW 8 cells (Fig. 1), a lymphosarcoma of a BALB/c mouse derived from *in vitro* infection of spleen cells with Abelson leukaemia virus. Cell growth continued normally for one or two doublings, and then was completely inhibited in the presence of 5 μg ml^{-1} LPS. Growth of PU-5-1, a spontaneous BALB/c B-type lymphoma[9] was inhibited by LPS at 5–50 μg ml^{-1} without a delay (Fig. 1). LPS from *E. coli* (W 055:B5 and 0111:B4, Difco) gave similar results. Lipid A derived from LPS by mild acid hydrolysis also inhibited RAW 8 and PU-5-1 cell growth at 5–20 μg ml^{-1} (not shown). These concentrations of LPS and lipid A which are inhibitory to the tumour cells were previously shown to be optimally mitogenic for normal spleen B lymphocytes[4,8].

Cell lines which are not sensitive to LPS inhibition of growth are listed in Table 1. Among murine tumours these include. θ^+ T lymphomas, myelomas, a myeloid leukaemia, an erythroid leukaemia, and a mastocytoma. Some cell lines show a partial inhibition of DNA synthesis 24 h after LPS addition, such as the T lymphoma S49[16], but DNA synthesis resumes and overall growth does not seem to be affected. A number of human lymphoid cell lines with surface immunoglobulin, considered to be B cells, and a marmoset T cell line are also unaffected by LPS (Table 1). A human myeloma line[17], RPMI 8226, is partially inhibited by LPS.

Experiments were performed to determine the sequence of events during the LPS inhibition of synthesis of macromolecules. Figure 2 shows that 20 μg ml^{-1} LPS causes a rapid inhibition of incorporation of ^{3}H-thymidine into DNA in RAW 8 cells, followed by a decrease in apparent RNA synthesis, both approaching 30–40% of control levels by 24 h. As two doublings occur before growth stops, one possibility is that an early event involves the LPS inhibition of transport of nucleic acid precursors rather than direct inhibition of DNA synthesis. Protein synthesis, as measured by the uptake of an essential amino acid, continues unaffected for more than 24 h before showing impairment. PU-5-1 cells also exhibit a rapid decline of incorporation into DNA, but not into RNA or protein (Fig. 2).

As cells remained viable for up to 5 d during LPS inhibition of growth, reversal of the LPS effect was tested. Both RAW 8 and PU-5-1 cells, cultured in the presence of 20 μg ml^{-1} LPS for 2 d, resumed DNA synthesis and multiplication when washed and recultured without LPS (not shown).

A screening was made of drugs with biological effects similar to LPS. BCG is an immunological adjuvant stimulating the reticuloendothelial system[18], and synthetic polyribonucleotides have toxic and adjuvant properties like LPS[19], but BCG (at 4 × 10^5 viable bacteria ml^{-1}; Eli Lilly), poly(I)·poly(C) (100 μg ml^{-1}; P L Biochemicals) and poly(A)·poly(U) (100 μg ml^{-1}; Miles Laboratories) did not inhibit growth of RAW 8 cells. Some thymus-independent antigens such as dextran (molecular weight 500,000, Pharmacia) and polyvinyl pyrrolidone (molecular weight 160,000, Baker; molecular weight 360,000, Sigma) are reported to be mitogenic specifically for B lymphocytes[20], as is LPS, but do not affect RAW 8 growth at 1 mg ml^{-1}. Dextran and zymosan, like LPS, activate complement components[21], which bind to B lymphocytes. Zymosan caused only moderate inhibition of RAW 8 growth at 1 mg ml^{-1} (Sigma, 50% of control cell number at day 4 as in Fig. 1) and the LPS inhibition occurred equally well in fresh or heat-inactivated foetal calf serum, indicating that complement is not involved.

A variety of microbiological products and synthetic polynucleotides are under investigation for nonspecific stimulation of host immunological resistance to tumours[18]. LPS and endotoxins are reported to have inhibitory effects on tumours *in vivo*[22], and this has been correlated with the local Schwartzman reaction and haemorrhagic necrosis[23]. With some tumours, the endotoxin effect may be mediated by factors released by the host rather than a direct action on the tumour[23]. The experiments described here suggest that certain lymphosarcomas may be susceptible also to direct inhibition by LPS. In preliminary experiments, mice given RAW 8 and PU-5-1 tumour cells, preincubated 1 h with LPS, or mice treated with LPS injections 2 d after innoculation, survived significantly longer than controls. LPS treatment did not increase survival of mice with other types of tumours.

Not all tumours derived from B lymphocytes are inhibited by LPS. Mouse myelomas and human B lymphoid lines are

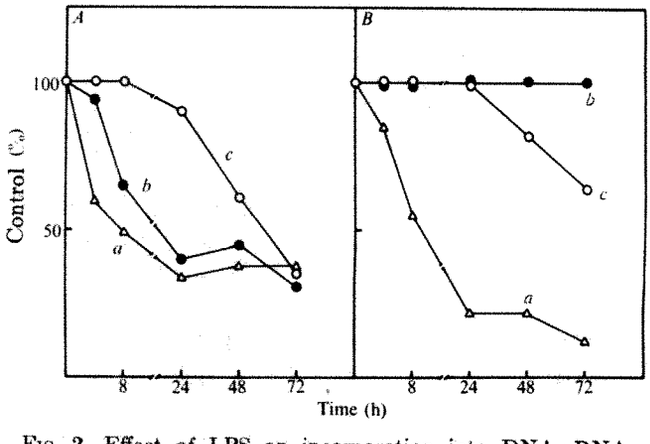

FIG. 2 Effect of LPS on incorporation into DNA, RNA and protein. Two ml cultures of *A*, RAW 8 or *B*, PU-5-1 were innoculated with or without 20 μg ml^{-1} LPS as in Fig. 1. At the times shown, duplicate dishes were incubated 1 h with 1 μCi ^{3}H-thymidine (50 Ci mmole^{-1}), 1 μCi ^{3}H-uridine (25 ci mmole)$^{-1}$, or 10 μCi ^{3}H-leucine (medium contains 0.8 mM leucine) to measure incorporation into, *a*, DNA; *b*, RNA or, *c*, protein, respectively. At the end of 1 h, the cells were collected and TCA-precipitable radioactivity determined. Each point is the mean of measurements from duplicate cultures which agreed within 10%. Results are shown as incorporation in the presence of LPS as a % of control cultures.

resistant (Table 1). There may be some types of human lymphosarcomas, however, which resemble RAW 8 and PU-5-1 in LPS sensitivity. Human peripheral blood lymphocytes[24] and spleen cells (P.R., and I.N., unpublished) do not respond to the mitogenic effect of LPS. LPS is not mitogenic or toxic to the mouse strain C3H/HeJ (ref. 25). Experiments are in progress to induce Abelson leukaemia virus tumours in these mice to see which biological activities are correlated with lymphosarcoma inhibition.

The inhibition of B lymphomas by LPS which is a mitogen for normal B lymphocytes is curious. A similar paradox was seen in the toxicity of PHA, a T lymphocyte mitogen, for T lymphomas but not other tumours[16,26]. The stimulating signals from the mitogens on the already dividing tumour cells may result in a push to a differentiated end cell type incapable of further division. Further proof is needed that the LPS-sensitive cells described here are tumours of B lymphocytes rather than of a form of monocyte as LPS is reported to have inhibitory effects on macrophages or phagocytic mononuclear cells[27].

This work was supported by grants from the Rockefeller Foundation and National Science Foundation. In addition, we thank Dr Melvin Cohn for support from grants from the National Institute of Allergy and Infectious Diseases.

Complement-mediated mixed aggregation of murine spleen cells

RECEPTORS on the surface at B cells for the fixed C3 component of complement have previously been studied by investigating the adherence to lymphocytes of complement-coated immune complexes and their function interpreted in the light of this reaction[1–10]. Other nucleated cells, however, notably macrophages, in the secondary lymphoid organs, also have receptors for fixed C3 (refs 3 and 4). It is therefore possible that alexinated complexes might mediate mixed adherence of different cell types which could have more significant functional consequences for complement receptor lymphocytes than just direct binding to their C3 receptors.

In vivo and *in vitro* studies indicate that C3 plays a part in the induction of thymus-dependent humoral antibody formation, but not in the response of B cells either to mitogens or thymus-independent antigens (refs 11, 12, 12a and unpublished results of M.B.P.). I have suggested on the basis of this evidence that C3 fixed on antigen-containing complexes might, as a consequence of its interaction with cell surface C3 receptors, enhance or facilitate T-dependent presentation of antigen to B cells at the macrophage surface (refs 11 and 13 and M.B.P., unpublished). Here I confirm the feasibility of this model and demonstrate the complement-mediated mixed adherence of spleen cells which results from binding of fixed C3 to cell surface C3 receptors.

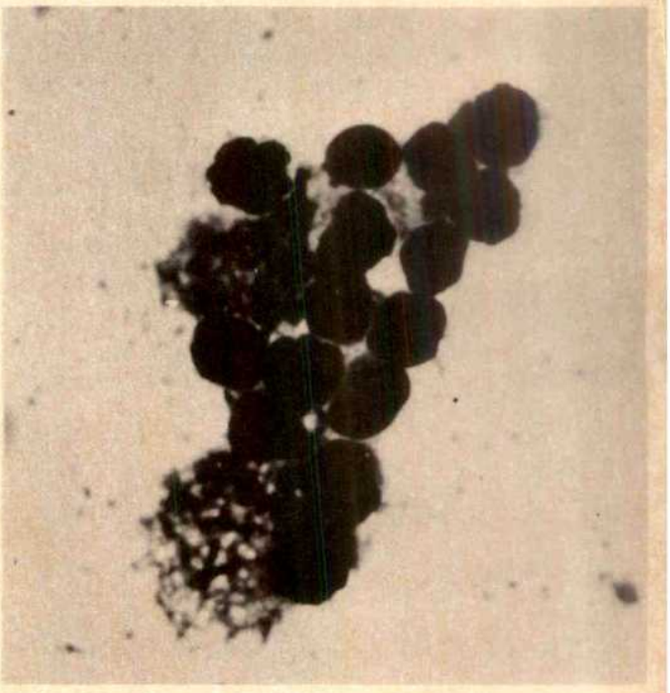

FIG. 1 Complement-mediated spleen cell aggregation. A dissociated spleen cell suspension from a mouse which had received 0.2 ml of Freund's complete adjuvant by intraperitoneal injection 3 weeks previously was rotated at 37°C for 45 min with fresh autologous serum (1/5 in CFT). The appearance of a typical cell clump in a fixed preparation obtained at the end of incubation, stained with Giemsa stain is shown. Cells with morphology characteristic of small lymphocytes, macrophages and blast cells were present. (Magnification × 1,550).

* Lymphocyte suspensions were rotated for 45 min at 37°C with active or inactive complement.
† Cell suspensions of spleens from normal mice, mice which had received an intraperitoneal injection of 0.1 ml of complete Freund's adjuvant during the preceding month, or of normal adult thymus cells.
‡ NMS, Fresh autologous normal mouse serum; NMS/inact, same serum heated to 56°C for 30 min; NMS/EDTA, same serum containing 0.01 M EDTA.
§ CFT or EDTA to 0.01 M added to cell suspensions in complement after 45 min incubation and rotation continued for further 15 min.
‖ Cell suspensions incubated for 45 min with complement were washed in CFT and then incubated at room temperature with either eluted anti-C3 antibodies or the IgG_1 fraction of anti-mouse C3.
¶ Number of clumps of >3 cells among 500 free nucleated cells expressed as a %.
** Approximate mean of the number of cells in the clumps.

Lymphoid cells were prepared by crushing the freshly removed spleens or thymuses of adult BALB/c mice with a silicone rubber bung and suspending the cells in complement fixation test diluent (CFT) (veronal buffered physiological saline containing Ca^{2+}, Mg^{2+}, gelatin 0.1 % w/v and 0.015 M sodium azide). Debris and clumps were removed by rapid filtration through separate 2.0 ml cotton wool columns for individual organs; the resulting suspensions after two washes in CFT at 4° C consisted exclusively of single cells. Each mouse was exsanguinated, the serum separated within 12 h at room temperature and kept at 4° C until use on the same day. For the production of complement-mediated cell clumps, lymphoid cell suspensions (5×10^6–15×10^6 cells ml^{-1}) in CFT were rotated (20 r.p.m.) in sealed plastic tubes at 37° C for 45 min with autologous complement at a final concentration of 1:5. Control tubes contained either inactivated (56° C, 30 min), autologous complement or fresh complement containing 0.01 M EDTA. After rotation, the mixture was mounted on siliconised slides and the number of nucleated cell clumps, consisting of three or more cells, amongst 500 free nucleated cells was counted under phase contrast. Dried smears of preparations were fixed with formol-saline and stained with May–Grunwald or Giemsa stain.

For treatment of formed clumps with EDTA, 0.2 M EDTA was added to a final concentration of 0.01 M and the suspensions were then reincubated on the rotator for a further 15 min. For treatment with anti-C3 antibodies, complement-treated lymphoid cell preparations were first washed twice in CFT, then incubated at room temperature with 100 μg ml^{-1} of either isolated sheep anti-mouse C3 antibodies or the IgG_1 fraction of the same antiserum from which all anti-C3 activity had been absorbed (M.B.P., A. J. Bell and I. F. Rowe, unpublished). The anti-C3 preparation used had 170 μg ml^{-1} of protein and a titre of 1:256 for agglutination of 1% EAC.

For the detection of cells with complement receptors, preparations were first washed twice with CFT, centrifuging at 90g for 5 min at room temperature. Indicator cells bearing fixed murine C3 were prepared by sensitising sheep erythrocytes (E) with 6 MHD of IgM rabbit anti-sheep erythrocyte antibody (A) and then alexinating them by incubation (15 min, 37° C) of 1% EA with 1:10 fresh normal mouse complement (C). The EAC were washed twice in CFT before use. Lymphoid cells (20 μl at approximately 2×10^6 cells ml^{-1}) and 0.5% EAC were mixed in siliconised glass Rh rubes and centrifuged at 90g for 5 min at 4° C. The cell pellet was then gently but thoroughly resuspended with a Pasteur pipette and mounted in 0.5% toluidine blue on siliconised slides. Nucleated cells with three or more adherent red cells were scored as rosettes and the proportion of these among at least 200 nucleated cells was counted for each tube. In some experiments, parallel assays in which EDTA to a final concentration of 0.02 M was present were included. Four replicates of each assay were performed, and the % of rosette-forming cells was corrected for the number of rosettes formed by EA instead of EAC.

Incubation of a suspension of normal mouse spleen cells with fresh autologous serum induced the formation of clumps of cells (Table 1). The size and number of clumps were greater when spleen cells were used from mice which had received an intraperitoneal injection of complete Freund's adjuvant in the preceding 2–4 weeks. If the serum was inactivated by heating at 56° C for 30 min, or if it was made to 0.01 M EDTA, no cell clumps formed, nor did they if cell suspensions were incubated in the absence of serum. The formation of clumps was optimal after about 45 min of incubation. Continued rotation at 37° C was associated with progressive dissolution of the aggregates; they were, however, more stable on standing at room temperature and persisted unchanged for up to 48 h at 4° C. The clumps consisted of a heterogeneous population of cells which included small lymphocytes, macrophages, occasional polymorphs and, when stimulated spleens were used, occasional blast cells (Fig. 1). Thymus cell suspensions did not aggregate when incubated with complement under the same conditions.

Incubation of the source of complement with the C3-cleaving protein (CoF) of cobra venom (refs 14 and 15 and M.B.P., unpublished) so as to induce complete conversion of C3 on antigen–antibody crossed electrophoresis rendered it inactive in the production of cell clumps. Confirmation of specific dependence of the phenomenon on C3 was obtained by incubating washed clumps at room temperature with specific eluted anti-mouse C3 antibodies; this resulted in almost complete dissolution of the aggregates (Table 1). Addition of EDTA to 0.01 M to spleen cell suspensions clumped by complement resulted in rapid and complete dissociation of clumps (Table 1), suggesting that macrophages, (to which, in the mouse, the adherence of fixed C3 requires magnesium ions[3]), are involved.

If complement-clumped spleen cell preparations were washed and then rosetted with EAC in the presence of divalent cations, numerous red cells adhered to the clumps and the overall proportion of rosettes on mononuclear cells was diminished by comparison with the initial spleen cell suspension untreated with complement (Table 1). When the

‡ The presence or absence of appreciable clumping of spleen cells. When clumps were present many indicator cells adhered to them.

clumped preparations were rosetted in the presence of 0.01 M EDTA the clumps dissociated, but there was an even greater reduction in the proportion of rosettes formed. The numbers of rosettes formed by clumped preparations which had been dissociated by EDTA, before rosetting in the presence and absence of divalent cations, showed a similar degree of reduction in comparison with the values obtained with the starting preparation. In contrast, treatment of spleen cells with inactivated mouse serum had no effect on the subsequent capacity of the cells to form rosettes with EAC (Table 2). These results suggest first, that after incubation of spleen cells with complement, cells with C3 receptors are included in the clumps; second, that as most of the rosettes which do form among the complement-treated cells are inhibitable by EDTA, and are therefore presumably on macrophages, the lymphocyte C3 receptors are apparently 'blocked' following incubation with complement and do not bind EAC[16].

Spontaneous dissociation of the complement-mediated clumps in the continued presence of the complement source at 37° C may have resulted, at least in part, from alternative pathway-mediated dissociation of fixed C3 from B cells[17]. This is probably due to generation of fluid-phase C3 fragments which have been shown in both a homologous human system (ref. 11 and M.B.P., and A. E. Butterworth, unpublished) and a mixed mouse–guinea pig system[18] to compete with fixed C3 for the C3 receptors. The fact that C3-dependent mixed cell adherence described here does reverse spontanously provides further support for the model which has been proposed for a possible role of this process in cell cooperation (ref. 11 and M.B.P., unpublished).

Complement-mediated C3-dependent aggregation of the different cell types in spleen cell suspensions which bear receptors for fixed C3 is of interest for several reasons. First, it illustrates the feasibility of an *in vivo* role for C3 in mediating the approximation of different cell types, particularly B cells and macrophages, which may be relevant to the mechanisms of cell cooperation in the induction of antibody production. Second, it provides evidence for the existence in normal spleens, and possibly to a greater extent in the spleens of mice stimulated by antigen, of a cell-associated mechanisms or mechanisms capable of fixing C3.

This work was undertaken during tenure of a Medical Research Council research fellowship.

Role of heterochromatin in the control of cell cycle duration

RECENTLY Bennett has demonstrated that most annual plants have less nuclear DNA than perennial plants[1]. Since there is a positive correlation between DNA content and minimum duration of the mitotic cell cycle[2], Bennett suggested that low DNA content and short cycles might be factors determining the generation time of short-lived plants. These assumptions also fit the general findings that DNA contents have increased strikingly during general evolution[3] but have decreased during specialisation[4–6].

Although the progression from DNA-rich conservative species to DNA-poor advanced species could also be demonstrated in some perennial Anthemideae (Asteraceae, Dicotyledones)[7], several annuals have been found in this subfamily which have significantly more DNA than perennials of the same genera[8]. In spite of this, the annual species develop much more rapidly than the perennials. Therefore, a factor unconnected with nuclear DNA content might be expected to play a role in the control of cell cycle and generation times in those species.

I have studied the relationship between nuclear DNA content, percentage of heterochromatin, and cell cycle duration in the genera *Anacyclus*, *Anthemis*, and *Artemisia*. I have analysed three perennial species, three annual species with a higher DNA content, and two annual species with a lower DNA content than the related perennials. I found evidence that the amount of heterochromatin per genome is related to the reduction of cell cycle times in annual plants with large DNA contents.

Seedlings were grown in controlled environment chambers at 22° C and 15 h light; root tips were fixed in ethanol:acetic acid (3:1) and Feulgen-stained for DNA measurement by cytophotometry. The roots were immersed in a solution of 10 μCi ml^{-1} 6-^{3}H-thymidine specific activty 26 C $mmol^{-1}$) at 22° C for 1 h and fixed every other hour for 2 d. Labelled metaphases were counted after an exposure time of 3 d.

The duration of the mitotic cell cycle can be estimated for every species for which the DNA content is known,

TABLE 1 Nuclear DNA contents, heterochromatin content and duration of cell cycle in root tips of annual and perennial *Anthemideae*

Species	Habit	DNA (10^{-12} g per 2C nucleus)	Heterochromatin-DNA (% of total DNA)	Cell cycle time (h) Expected	Actual	Difference

—*annua* L.	Annual	4.05	14.13	10.5	7.7	−2.8

DNA content was measured in Feulgen-stained nuclei by the two-wavelength method of cytophotometry[14]; *Allium cepa* nuclei have been used for the conversion into absolute values. The percentage of DNA within the heterochromatic portion of the genome was calculated from measurements, after the extinction values for euchromatin had been set to zero[15]. The expected cell cycle times were calculated from the diagram given by Evans *et al.*[2]. The actual duration was established after pulse labelling, by the method of labelled mitoses curves[16]. Striking negative differences between the expected and the actual cycle times can be seen in species with high amounts of heterochromatin-DNA, especially in some annuals.

because there is a linear relationship between these two parameters[2]. In some of the species studied, however, the measured cycle duration differed significantly from the expected value (Table 1). In all annuals tested the cell cycle time was shorter than in the related perennials, in spite of the greater DNA content in three of the annual species. These three species have a proportionately greater amount of DNA as heterochromatin than their perennial relatives.

My results indicate that the nuclear DNA content can increase by the addition of heterochromatin without lengthening of the cell cycle. The cycle may even become shorter.

The percentage of heterochromatin within a given genome might, therefore, represent a correcting factor in the control of the duration of the cell cycle, in addition to the nuclear DNA content (the basic determinant). Heterochromatin is rich in repetitive DNA[9] and replicates faster than euchromatin[10]. Thus annual species can become able to grow and develop rapidly, either by decreasing the nuclear DNA content or by increasing the DNA content through an increase in the percentage of heterochromatin. An increase in DNA, when found in specialised and progressive groups, is possibly always accompanied by a proportionally greater increase in repetitive sequences. Fox[11] reported, for example, that the heterochromatic portion of the genome in several beetles increased faster than did the euchromatic portion; increasing amounts of repetitive DNA were also found to be correlated with increasing DNA content in conifers[12]. In *Vicia*, differences between species-specific DNA contents were reported to be caused by different numbers of rRNA genes, which appear in the form of heterochromatic chromosome segments[13]. Thus, the amount of heterochromatin is evidently an important factor in determining both nuclear DNA content and growth rate parameters. Details will be published in a forthcoming paper.

I thank Professor Friedrich Ehrendorfer for suggestions.

Mode of action of soybean trypsin inhibitor (Kunitz) as a model for specific protein–protein interactions

THE protein trypsin inhibitors are proteins which bind very strongly to trypsin, blocking its active site (K_i = 10^{-9} to 10^{-14} M). We have carried out a crystal structure analysis of the complex of soybean trypsin inhibitor (Kunitz) (STI), one of the largest inhibitors, with porcine trypsin. Huber and his colleagues have determined the structure of a complex of a small inhibitor, bovine pancreatic trypsin inhibitor (Kunitz) (PTI), with bovine trypsin[1]. These studies improve our understanding of the catalytic mechanism of trypsin, demonstrate that various trypsin inhibitors act in a similar way and provide insight into the development of strong, specific binding between protein molecules.

From preliminary results on the crystal structure of isolated PTI[2], using available knowledge about chymotrypsin[3] and trypsin[4], it was possible to predict a unique mode of binding in which the inhibitor is oriented similarly to a true trypsin substrate[4,5]. This prediction was confirmed by the crystal structure analysis of the complex of PTI with trypsin[1].

Native PTI is not detectably modified by trypsin, but cleavage of a specific peptide bond of STI (Arg 63′–Ile 64′) is catalysed by trypsin. An equilibrium between STI and a modified form, in which this bond is hydrolysed, has been demonstrated[6]. This provides strong evidence that binding of STI to the catalytic site of trypsin mimics the productive mode of substrate binding.

The STI:porcine trypsin complex was crystallised and the first isomorphous derivative was discovered by H. T. Wright in this laboratory. The structure analysis has been taken to a resolution of 2.6 Å. The STI molecule, omitting certain uninterpretable regions, is shown in Fig. 1. As in the case of PTI, we observe that only a very small part of the molecule

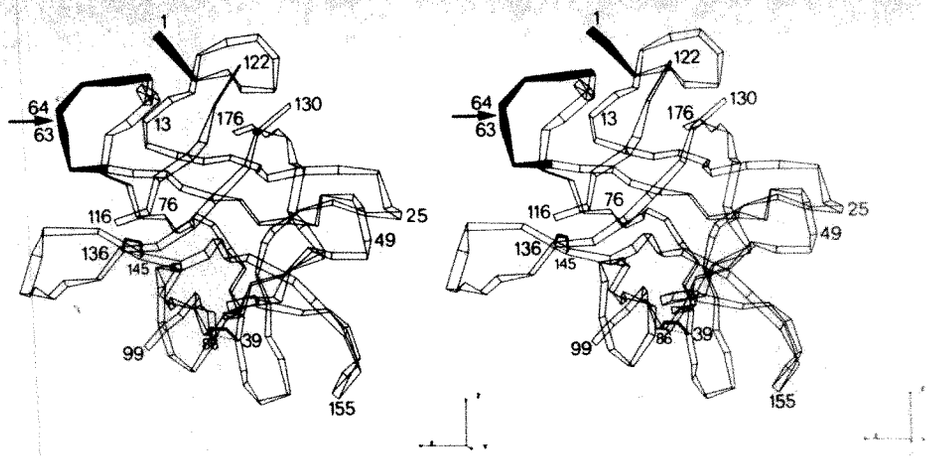

FIG. 1 Conformation of the polypeptide chain of soybean trypsin inhibitor as determined from the crystal structure of the complex with trypsin, and the amino acid sequence[7]. Residues 107′–115′, 123′–129′, 177′–181′ could not be located in the electron density map; as a consequence, the identification of residues 116′–122′ is tentative. The two disulphide bridges are indicated. Residues which make contact with trypsin are blackened : the arrow indicates the scissile bond 63′–64′.

[*Note added in proof.* More accurate co-ordinates show that residues 13′, 60′, 71′, 72′ also make a few contacts with trypsin.]

is involved in the contact region. If the inhibition of trypsin is the function of these molecules, most of the protein does nothing more than stabilise the structure.

In the PTI complex a disulphide bridge adjacent to the active site effectively excludes access of water to the bond (Lys 15′–Arg 16′) which lies at the active site of trypsin[5]. In the STI complex water is also excluded from the catalytic site, mainly by the chain (11′–14′), but this is held in place only by a few hydrogen bonds and van der Waals' contacts. The looser attachment may account for the measurable rate of hydrolysis of the STI complex of trypsin.

Both PTI and STI have a positively charged amino acid at P_1 to occupy the primary specificity pocket of the enzyme (Arg 63′ in STI). The main chain NH of this amino acid is hydrogen-bonded to CO(214), as found in a chymotrypsin: substrate complex[8]. Interactions of adjacent residues in both the STI and PTI complexes (Fig. 2) agree with the interactions proposed for polypeptide substrates of chymotrypsin[9–12]: (a) from a study of models Segal *et al.*[9] pointed out that a bulky group at P_2 can interact hydrophobically with Ile 99. This is observed in both PTI and in STI, where P_2 is Tyr 62′. (b) At P_3 which is Ser 61′ in STI, the NH group is hydrogen bonded to CO(216) in both complexes. Segal *et al.*[9] found a similar interaction for substrate analogues of γ-chymotrypsin. A second hydrogen bond which they found, involving NH(216), cannot occur in trypsin because it is differently oriented, as a consequence of the deletion of residue 218 (ref. 13). (c) In both complexes a residue in P_1' (Leu 64′ in STI) makes hydrophobic contacts with the disulphide bridge 42–58. It was recently shown that interactions at P_1' accelerate deacylation of acylchymotrypsins by 50–100 times[11]. There was no evidence of enhanced binding of the deacylating agent.

Structural models[5] showed that the favourable interactions at P_1' could not occur in the Michaelis complex with a polypeptide substrate, because of unfavourable interactions of the substrate with the enzyme's active serine, Ser-195 (ref. 11). Similarly when the peptide bond P_1–P_1' is hydrolysed, the residue at P_1' is forced away from P_1 by about 1 Å and the favourable interactions are again disrupted. In an intermediate state, when the carbonyl group of the scissile bond is bonded to both Ser-195 and its amide nitrogen, the substrate could make its best fit to the surface of the enzyme. This explained how the energy of this interaction could strain the enzyme:substrate complex toward the transition state, reducing the activation energy of acylation, rather than improving the binding constant[11].

In addition to the primary binding at P_1, all three interactions (a)–(c) are observed in both inhibitor complexes, which therefore both exhibit the mode of binding already inferred as the productive mode for trypsin substrates. The similarity of the interactions at P_3–P_2–P_1–P_1' is confirmed by the close agreement of the recorded dihedral angles in the three intervening peptide bonds (Table 1), which must be close to experimental error. Although the agreement of chain conformation extends no further, one additional similarity exists: (d) In both PTI[1] and STI complexes, arginine is found at P_2'. In each case its guanidinium group lies parallel to Tyr-151 probably forming a charge-transfer complex. The guanidinium group is hydrogen bonded to CO-40. Despite this similarity, the main chain conformations at P_2' are

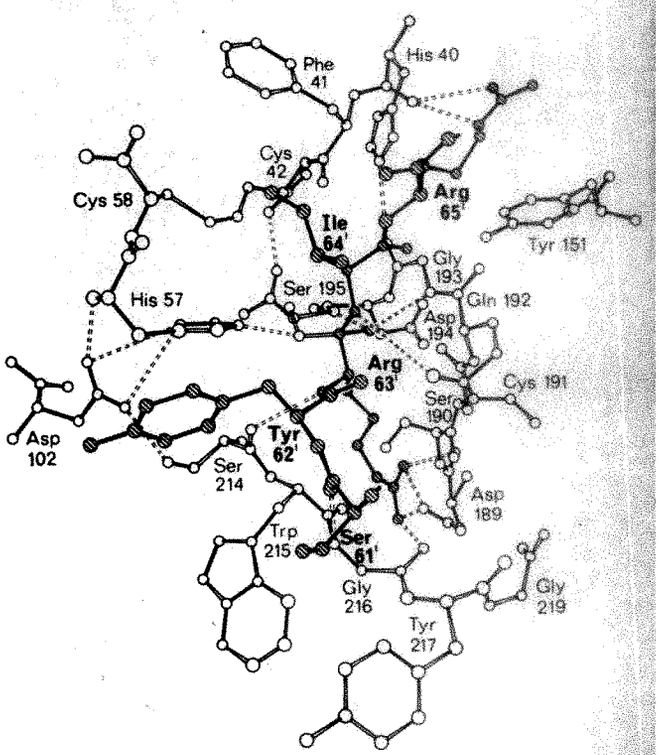

FIG. 2 Residues 61′–65′ of soybean trypsin inhibitor and the parts of the trypsin molecule involved in binding them. Atoms of the inhibitor molecule are shaded and many of the interactions which they make are mentioned in the text. The carbonyl carbon of the scissle peptide bond 63′–64′ is shown tetrahedrally coordinated. Trypsin residues Asn-97 and Leu-99 which lie in front of Asp-102 and touch the distal part of Tyr-62′ have been omitted for clarity.

* R. Huber *et al.*, private communication

completely different in the two inhibitor complexes. Other trypsin inhibitors do not have arginine at P_2'.

Rühlmann *et al.*[1] were obliged to interpret the electron density at the active site of the PTI complex in the form of a tetrahedral intermediate, in which there is a covalent bond between the enzyme and inhibitor, whereas the peptide Lys 15′–Ala 16′ at the active site is still linked. This tetrahedral form had been generally assumed to exist in the chemical pathway[14,15] but in a normal hydrolysis reaction its lifetime is so short that it had never been convincingly demonstrated.

In Table 2 we give the distances observed in STI between C^{α} (Arg 63′), C^{β} (Ser 195) and C^{α} (Ile 64′), together with the distances expected on stereochemical grounds for the various possible intermediate forms. The Michaelis and acyl forms both cause impossible crowding at the active site. We feel that this provides conclusive evidence that the STI complex is also in the tetrahedral form.

Structural data have indicated two aspects of the interaction between trypsin-like enzymes and their substrates which may favour the tetrahedral intermediate. One of these concerns the binding of the leaving group at P_1' and has been described above. The other concerns hydrogen bonds from the NH groups of Gly-193 and Ser-195 to the carbonyl group of the scissile bond, which are better oriented when the carbonyl carbon becomes tetrahedral[16] and will be strengthened by any negative charge which exists on the oxygen. In the tetrahedral intermediate the buried negative charge, which may be thought of as originating from COO^- (Asp-102), is maximally delocalised across His-57 and the tetrahedral ester group.

The tetrahedral intermediate is close to the transition state of the reaction[17,18]. The essential requirement for a catalyst is to stabilise the transition state[19] and an effective enzyme must provide a means of doing this[20]. The two trypsin inhibitors do this so effectively that the tetrahedral intermediate constitutes a minimum of free energy in the reaction pathway, and at least in crystals it becomes the most abundant state. Formation of a covalent bond between the enzyme and the inhibitor does not in itself explain the strong binding, as is shown by the high affinity of PTI, STI and other inhibitors for anhydrotrypsin, in which the oxygen of Ser-195 has been removed[21,22]. In anhydrotrypsin the overcrowding at the active site is relieved, and the intact inhibitor can bind favourably to the active site. Calorimetric measurements show that the binding of STI to trypsin is endothermic[23], reflecting the relatively high enthalpy of the tetrahedral form, but a large entropy term stabilises the complex.

The entropy of association between protein molecules derives largely from the shells of immobilised, or partly ordered, water molecules which surround the two separate molecules. These are reduced in volume on association[24]. An external polar group is normally hydrogen-bonded to a water molecule, which becomes immobilised. On association, provided that such hydrogen bonds are exchanged for an intermolecular hydrogen bond, there is little change of enthalpy; but the release of immobilised water molecules may be an important contribution to the entropy of association.

There is an important difference between the association of an enzyme with a folded protein molecule which makes a perfect fit, and the binding of a loosely coiled molecule. When a small polypeptide substrate binds to the enzyme, its loss of internal degrees of freedom reduces the free energy of binding. Binding of a correctly folded protein molecule may be achieved without change of internal freedom. These entropic factors, even over the small interaction areas observed in PTI and STI, are evidently sufficient to yield the high association constants which are observed.

Enzyme–substrate interactions have evolved to lower the activation energy of a chemical reaction step. These studies show in detail how the energetics of these interactions may provide the driving force for very strong binding, with a highly specific recognition system. To evolve a receptor, which recognises a specific effector and signals its presence to a linked biochemical system, one would require in addition that substrate binding triggered a structural change.

TABLE 2 Distances at the active site compared with expected distances for different intermediate forms of the complex

	$C^{\alpha}(63')$–$C^{\beta}(195)$ (Å)	$C^{\alpha}(63')$–$C^{\alpha}(64')$ (Å)
Observed distance	3.7	3.9
Expected distances:		
Michaelis complex	5.2	3.8
Tetrahedral intermediate	3.7	3.8
Acyl enzyme	3.7	5.0

Prostaglandins and the regulation of uterine blood flow in pregnancy

In late pregnancy, uterine blood flow (UBF) has increased by as much as thirty- to forty-fold[1] and uterine vascular reactivity to vasoconstrictor hormones and adrenergic nerve stimulation has decreased[2,3]. For example, angiotensin II increases blood flow to the gravid uterus[3,4], an uncommon response to this agent which is the most potent vasoconstrictor hormone[5]. Prostaglandins of the E series (PGE) have been reported to maintain some regional blood flows[6,7] and to modulate the vasoconstrictor activity of angiotensin II and noradrenaline[8,9]. In view of the findings that the uterus synthesises prostaglandins[10,11], we have investigated the possible participation of locally synthesised prostaglandins in the regulation of blood flow and vascular reactivity of the gravid uterus.

Mongrel dogs in late pregnancy weighing 20–30 kg were anaesthetised with morphine sulphate (2 mg kg^{-1}, subcutaneously) and chloralose (100 mg kg^{-1}, intravenously). The trachea was cannulated and the lungs were ventilated mechanically. The abdominal cavity was opened by a midline incision. A short segment of the main uterine artery of one horn was isolated from the surrounding tissue. Blood flow to this horn was measured by an electromagnetic flowmeter. In three experiments, we measured blood flows to both uterine horns which were similar. Mean aortic blood pressure (MABP) was measured by a Statham transducer via a catheter inserted into a brachial artery. A direct writer (Hewlett-Packard) was used to record UBF and MABP. The assay of PGE-like material ('PGE') in blood which has been reported[12] requires chromatographing acidic lipid extracts of the blood on thin-layer plates, after which eluates from the PGE zones of the plates were then assayed *in vitro* by bracket assay using the method of Vane[13] in which three tissues, rat stomach strip, rat colon and chick rectum are superfused in series with Krebs solution. Samples of blood (50 ml) were obtained from a cannula in the uterine vein. Angiotensin II was given intravenously for 10–15 min, by a Braun continuous-infusion pump through a cannula inserted into the right forepaw vein. Indomethacin was administered intravenously in 10% alcohol in Krebs solution at doses which decreased UBF by more than 20%. This dose of indomethacin proved highly variable (2–120 mg kg^{-1}) in contrast to the dose required to effect similar reductions in renal blood flow in male dogs[6]. Student's *t* test for paired data and Wilcoxon's signed ranks test were used to determine statistical significance.

The mean basal concentration of 'PGE' in uterine venous blood in nine experiments was 0.39 ± 0.08 (range 0.11 to 0.92) ng ml^{-1}. In eight of these experiments, angiotensin II increased UBF from a mean control of 84 to 111 ml min^{-1} ($P < 0.05$), and MABP from a mean control of 100 to 118 mm Hg ($P < 0.01$) (Table 1). 'PGE' concentrations in uterine venous blood, measured at the time of maximal increase in UBF produced by angiotensin II infusion, increased in every instance; the mean concentrations of 'PGE' increased about two-fold, that is from 0.26 to 0.51 ng ml^{-1} ($P < 0.05$). Arterial levels of 'PGE' measured in one experiment were one-twentieth those in uterine venous blood. In six experiments, within 30 min of administration of indomethacin, MABP increased from a mean of 102 ± 6 to 113 ± 5 mm Hg ($P < 0.02$), UBF decreased from a mean of 89 ± 32 to 21 ± 5 ml min^{-1} ($P < 0.05$), and the concentration of 'PGE' in uterine venous blood decreased from a mean of 0.37 ± 0.12 to 0.03 ± 0.02 ng ml^{-1} ($P < 0.05$). After indomethacin, infusion of PGE_2 into the abdominal aorta at rates as high as 3,000 ng min^{-1} did not increase the depressed UBF. This finding which seems to contradict the importance of a PGE compound in regulating blood flow to the gravid uterus is understandable, if we assume that exogenous PGE_2 does not reach the active site within the uteroplacental circulation because of either degradation, binding or relative inaccessibility of injected PGE_2 to this site. To test this possibility, we used bradykinin which has been shown to release prostaglandins[14,15]. Indomethacin attenuated the uterine vasodilator action of bradykinin (100 ng kg^{-1} min^{-1}, intraaortic): in two experiments before indomethacin, bradykinin increased UBF by 56 and 64 ml min^{-1} (control 60 and 21 ml min^{-1}, respectively), whereas after indomethacin, bradykinin increased UBF by 4 and 16 ml min^{-1} (control 26 and 13 ml min^{-1}; respectively). Further, in the non-pregnant dog 'PGE' is not found in uterine venous blood (three experiments) and BK does not affect UBF. These results suggest that 'PGE' synthesised locally dilates the uterine vascular bed, although exogenous PGE_2 cannot. Similar results were ob-

tained with arachidonic acid, the precursor of PGE_2[16], which has also been shown to release PGE_2[14]. Thus, arachidonic acid increased UBF when given before, but not after indomethacin.

The levels of 'PGE' that we found in uterine venous blood are more than ten times those reported in the venous effluent of the hind limb[6] and are equal to or greater than those in renal venous blood[17]. The capacity of the kidney to synthesise prostaglandins is surpassed only by the seminal vesicle[18] and in view of our findings, perhaps by the gravid uterus as well. Since prostaglandins of the E series have been shown to oppose the vasoconstrictor activity of pressor systems[8], our findings of high uterine venous levels of 'PGE' which are increased further by angiotensin II may account in part for the increased UBF produced by angiotensin II and the altered reactivity of the uterine vasculature to other vasoconstrictor stimuli. Renin, which is found in abundance in the pregnant uterus[19] has been suggested to participate in the control of uterine vascular resistance[3], possibly through the generation of an angiotensin which in turn stimulates uterine prostaglandin synthesis. In this way, angiotensin-prostaglandin interactions may participate in the regulation of uterine blood flow. The importance for the uterine circulation of uninterrupted synthesis of prostaglandins by the gravid uterus was revealed after inhibition of prostaglandin synthetase with indomethacin[20]. Uterine blood flow fell to levels less than 30% of control. Simultaneously, the concentration of "PGE" in uterine venous effluent declined to a mean value less than 10% of control.

This work recalls our previous studies on the renal circulation: (1) continued production of PGE_2 was shown to maintain resting renal blood flow[6], and (2) angiotensin II and noradrenaline were shown to increase renal synthesis of PGE_2 above basal levels[8]. The importance of this function of the kidney was revealed after inhibition of prostaglandin synthetase by indomethacin. Thus, resting renal blood flow decreased by more than 40%[6] and the renal vasoconstrictor action of angiotensin II and noradrenaline increased several-fold[21]. The previously reported ameliorating effects of pregnancy on both experimental hypertension[22] and essential hypertension[23] may reside partially in the capacity of the gravid uterus to synthesise one or more substances which have antihypertensive properties, such as PGE_2[24]. Finally, we have not distinguished the site of origin within the uteroplacental circulation of the 'PGE' which appears in uterine venous blood. One or more sites including the foetal as well as the maternal components of the placenta, nor excluding the myometrium, should be considered. Thus, we were not able to relate changes in uterine blood flow after indomethacin to a primary effect on one or more of the several elements of the uteroplacental circulation.

Role of *rel* gene in translation during amino acid starvation in *Escherichia coli*

It has been thought that the *rel* gene in *Escherichia coli* is responsible for the stringent control of stable RNA synthesis dependent on a supply of amino acids, since the gene was identified as the site of mutation to the relaxed phenotype[1]. But in our previous reports[2,3], we suggested that mutational defects in *rel*⁻ cells are probably in the translational mechinery, the integrity of which may be required for stringent control. This supposition is based on the following observations: (1) When *rel*⁻ cells are shifted down in carbon or nitrogen source, the stringent control of RNA synthesis is observed in spite of their *rel*⁻ genotype[2,4]. Only when deprived of amino acids do *rel*⁻ cells fail to restrict RNA synthesis, in contrast to cells having the *rel*⁺ allele. (2) Ribosomal inhibitors like chloramphenicol abolish the stringent control in both *rel*⁺ and *rel*⁻ cells[2,5,6]. Furthermore, a cold-sensitive mutant defective in protein synthesis at low temperature carring a mutation in *spcA* locus, also shows the relaxed phenotype under non-permissive conditions[3]. It has been reported that several other mutants of *rel*⁺ strains having temperature-sensitive phenylalanyl-tRNA synthetase[7], peptidyl-tRNA hydrolase[8], or elongation factor G (ref. 9) all failed to control the synthesis of RNA at the higher temperature. This suggests that normal synthesis of protein is required for stringent control. (3) During shift-down of a carbon or nitrogen source there is no difference between the growth of *rel*⁺ and *rel*⁻ cells. Only after shift-down of amino acids do *rel*⁻ cells require a much longer lag period before they resume growth[2,10]. This is due to the inability of *rel*⁻ cells to carry out the normal synthesis of protein when the supply of amino-acids is limited.

The work described here was carried out to extend our previous reports[2,3] that the *rel*⁻ mutant is defective in translation under amino acid deprivation. We found that polysomes in the amino acid-starved *rel*⁺ cells function actively in protein synthesis while in *rel*⁻ cells they are inert.

When the cells growing in an amino acid-rich medium are shifted down to one poor in amino acids, *rel*⁺ cells are able to resume growth much more rapidly than *rel*⁻ cells[2]. Enzymes responsible for the synthesis of amino acids are produced immediately after shift-down in *rel*⁺ cells, but not in *rel*⁻ cells[2]. Formation of several other enzymes including β-galactosidase[11], alkaline phosphatase[12], and ornithine transcarbamylase[13] was also impaired in *rel*⁻ cells during amino acid starvation.

When the cells were shifted down to an amino acid-poor medium, the overall rate of protein synthesis was reduced to less than 10% of that in pre-shift conditions in both *rel*⁺ and *rel*⁻ strains (see zero time in Fig. 1*a* and *b*). But as shown in Fig. 1*a* the rate of protein synthesis in *rel*⁺ cells recovered rapidly during incubation in minimal medium and reached a plateau which was sufficient to maintain the growth of cells in shift-down conditions. On the other hand, the rate of protein synthesis in *rel*⁻ cells gradually declined (Fig. 1*b*). The potential protein synthetic activity as measured by incorporation of ^{14}C-phenylalanine in the presence of a mixture of twenty amino acids was preserved in *rel*⁺ cells during amino acid starvation, while in *rel*⁻ cells it decreased.

The change of the rate of RNA synthesis following the amino acid shift-down is also shown in Fig. 1. After deprivation of amino acids, RNA synthesis in *rel*⁺ cells was extremely

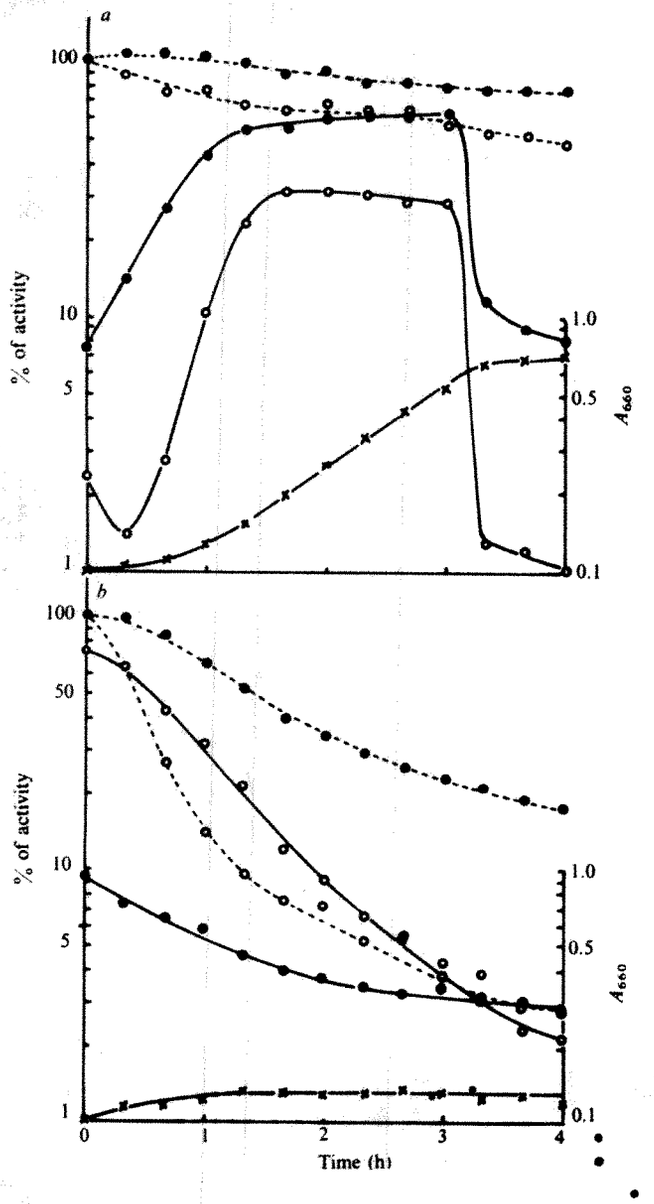

Fig. 1 Change in protein and RNA synthesis in *rel*⁺ and *rel*⁻ cells following the shift-down of amino acids. CP78(*rel*⁺) and CP79(*rel*⁻), isogenic except for the *rel* locus[14], were used. They are descendants of K12 strain and require leucine, threonine, histidine, arginine, and thiamine. Cells were grown at 37°C with shaking in glucose (0.4%) required amino acids (20 μg ml^{-1} each), thiamine (2 μg ml^{-1}), M9 medium; further supplemented with all twenty L-amino acids (0.1 mM each). The cultures grown to log phase were centrifuged, washed and resuspended in a fresh glucose-M9 medium containing only required amino acids and thiamine. During incubation in the shift-down medium, at the time indicated aliquots were withdrawn and the activities of protein and RNA syntheses, and the turbidity at 660 nm (1 cm light path) were estimated. For the measurement of protein synthesis, two samples (0.5 ml each) were taken and pipetted into two different test tubes; one contained 15 μl of ^{14}C-phenylalanine (5 μCi ml^{-1}; 0.25 μmol ml^{-1}) and 50 μl of distilled water, and the other contained 15 μl of ^{14}C-phenylalanine and 50 μl of nineteen L-amino acids mixture except phenylalanine (1 mM each). For RNA synthesis, 0.5 ml samples were added to the test tubes containing 15 μl of ^{3}H-uracil (5 μCi ml^{-1}; 0.25 μmol ml^{-1}) with or without 50 μl of a mixture of twenty amino acids (1 mM each) as above. After incubation for 10 min at 37°C, 3 ml of ice-cold 5% trichloroacetic acid was added. The precipitates were collected by filtration on Whatman GF83 glass fibre papers, washed three times with 3 ml of 5% trichloroacetic acid and then once with acetone. Radioactivity was determined in a liquid scintillation spectrometer using toulene-based counting mixture. Activities of protein and RNA syntheses were represented by the radioactivities incorporated per A_{660} nm of the culture. Solid lines indicate the activities which were measured by the incorporation of ^{14}C-phenylalanine or ^{3}H-uracil without addition of amino acids mixture. Dashed lines show the activities measured with addition of amino acids mixture (potential activity). *a*, CP78 (*rel*⁺); *b*, CP79 (*rel*⁻). ●, protein synthesis; ○, RNA synthesis; ×, cell growth.

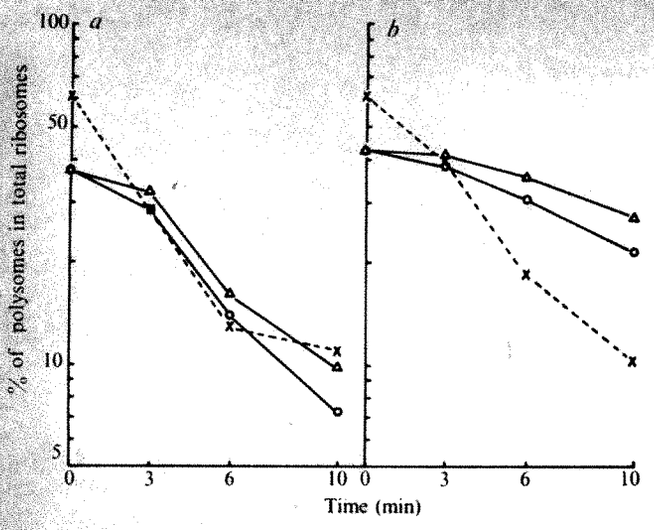

FIG. 2 Decay of polysomes in CP78 (*rel*$^+$) and CP79 (*rel*$^-$) in the presence of rifampicin. Cells, grown to log phase in a glucose-M9 medium supplemented with twenty amino acids, were collected, washed and resuspended in M9-buffer to approximately 7×10^8 cells ml. The cell suspension was poured into the flasks containing 0.6 ml of glucose (0.2 g ml^{-1}), 0.6 ml of thiamine (10 μg ml^{-1}), 0.6 ml of mixture of required amino acids (0.1 mg ml^{-1} each), and 3 ml of mixture of twenty amino acids (1 mM each) when specified. The total volume was adjusted to 30 ml. After incubation for 10 or 30 min 1 ml of rifampicin solution (6 mg ml^{-1}) was added to each flasks. The incubation was stopped by pouring over crushed ice at indicated times. Cell lysates were prepared according to the method of Godson[17]. The cells were collected by centrifugation and resuspended in 0.4 ml of 25% (w/v) sucrose solution containing 10 mM Tris-HCl (pH 8.1). Then to the cell suspension were added 50 μl of lysozyme (1 mg ml^{-1}) and 50 μl of EDTA (10 mM). After mixing by gentle swirling for 3 min in the cold, 0.5 ml of lytic mixture was added, which contained 40 mM Tris-HCl (*p*H 8.1), 1% (w/v) Brij-58, 20 mM $MgCl_2$, 0.2% (w/v) deoxycholate and 1 μg ml^{-1} DNase. Lysed solutions were centrifuged for 10 min at 10,000 r.p.m. to remove the cell membranes and debris. The lysates (3.4 A_{260} unit) were analysed in 4.6 ml of 0.4 M to 1.3 M linear sucrose density gradients containing 10 mM Tris-HCl (*p*H 7.5), 10 mM $MgCl_2$, and 60 mM KCl. Gradients were centrifuged in Spinco SW 50.1 rotor for 50 min at 45,000 r.p.m., then unloaded from the top with ISCO gradient fractionator, which monitored the optical density at 254 nm. The polysome content was determined by cutting and weighing the tracings after correction of the base lines. *a*, CP78 (*rel*$^+$); *b*, CP79 (rel$^-$). ×, Cells were incubated with twenty amino acids for 10 min before addition of rifampicin; ○, incubated in the medium containing only required amino acids for 10 min; △, incubated in the medium containing only required amino acids for 30 min.

suppressed, but it started to rise rapidly before the recovery of growth (Fig. 1*a*). The initial suppression of RNA synthesis in *rel*$^+$ cells is the consequence of stringent control. In the case of *rel*$^-$ cells, the rate of RNA synthesis was not restricted by deprivation of amino acids but during incubation in the minimal medium it declined gradually (Fig. 1*b*). Potential RNA synthesis, like protein synthesis was preserved in *rel*$^+$ cells, but *rel*$^-$ cells were not able to maintain the activity at pre-shift level.

We have suggested that the regulation of RNA synthesis observed in *rel*$^+$ bacteria is dependent on the function of protein synthesising machinery under shift-down conditions[2,3]. It seems that the cells having the *rel*$^+$ allele have the ability to carry out protein synthesis under a limiting supply of amino acids. This teleological significance of the function of the *rel* gene was not considered until the shift-down experiment was carried out, since in the experiments in which required amino acids are withheld, the amino acid auxotrophs are not able to grow (see refs 2 and 15).

When proteins are being synthesised actively in the cells, polysomes are in a dynamic state, being rapidly formed and degraded. Rapid degradation of the active polysomes can be observed when the synthesis of messenger RNA is blocked by addition of actinomycin or rifampicin. On the other hand, polysomes are stabilised and accumulated when ribosome movement on messenger RNA is arrested by ribosomal inhibitors such as chloramphenicol or fusidic acid (see ref. 16). The translational activity on polysomes can therefore be estimated by measuring the stability of polysomes after inhibition of messenger RNA synthesis by rifampicin.

We have measured the stability of polysomes of both *rel*$^+$ and *rel*$^-$ cells in either growth or amino acid shift-down conditions in the presence of rifampicin (Fig. 2). Polysomes in the actively growing cells of both *rel*$^+$ and *rel*$^-$ strains are degraded rapidly with halflife of about 3 to 4 min but the stability of polysomes in amino acid-deprived cells is distinctly different in *rel*$^+$ and *rel*$^-$ strains. Polysomes in amino acid-deprived *rel*$^+$ cells decay almost at the same rate as these in the growing cells although there is a lag before degradation starts (Fig. 2*a*). In a *rel*$^-$ strain, polysomes of cells incubated in an amino acid-deprived medium are much more stable than those of growing cells (Fig. 2*b*). The stability of polysomes is increased by prolonged incubation in the minimal medium.

These findings clearly indicate that the translation on polysomes in *rel*$^+$ cells is occurring actively even under the limiting supply of amino acids, whereas in amino acid-deprived *rel*$^-$ cells polysomes are inert, as when the ribosome movement is arrested by addition of chloramphenicol.

Ron[18] and Silengo[19] have reported essentially the same results as ours on polysome turnover in *rel*$^+$ and *rel*$^-$ bacteria. But Cozzone and Donini[20] have reported a conflicting result: that when *rel*$^+$ and *rel*$^-$ cells carrying temperature-sensitive valyl-tRNA synthetase are treated with rifampicin at a higher temperature, polysomes in both *rel*$^+$ and *rel*$^-$ cells decay as rapidly as those in growing cells under permissive conditions.

From the results of polysome turnover, it was expected that, under the amino acid-starved condition, proteins are synthesised normally on polysomes and released to the soluble fraction in *rel*$^+$ strains, but not in *rel*$^-$ strains. To prove this, we have carried out the following chase experiment. The amino acid-starved cells of both *rel*$^+$ and *rel*$^-$ strains were labelled for 1 min with ^{3}H-amino acids of high specific activity. After labelling, an excess of unlabelled amino-acids was added. Figure 3A shows the kinetics of incorporation of radioactive amino acids into the cell lysate and its acid-insoluble fraction with *rel*$^+$ and *rel*$^-$ cells. Although the specific activities of amino acids were reduced about a thousand-fold by addition of unlabelled amino-acids, the incorporation of radioactive amino acids into the acid-insoluble fraction was not suppressed immediately. In this experiment the amino acid pool of the cells contained radioactivity more than ten times higher than the protein fraction, since the protein synthesis was greatly reduced by amino acid starvation. Therefore, even after the addition of excess unlabelled amino acids there is a time lag before the labelled nascent polypeptides on polysomes are replaced by the unlabelled polypeptides (see Fig. 3C).

Figure 3B shows the pattern of sucrose density gradient centrifugation of lysates of *rel*$^+$ and *rel*$^-$ cells which were chased for 30 and 90 s by the addition of an excess of unlabelled amino-acids. Fig. 3C shows the time course of the incorporation of radioactive amino acids into the acid-insoluble fraction of polysomes, ribosomes, and supernatants calculated from the results of Fig. 3B. As expected, after the addition of unlabelled amino acids the labelled nascent polypeptides on polysomes in amino acid-starved *rel*$^+$ cells were displaced by unlabelled polypeptides and released to the supernatant fraction, while in amino acid-starved *rel*$^-$ cells the radioactive polypeptides were retained on polysomes.

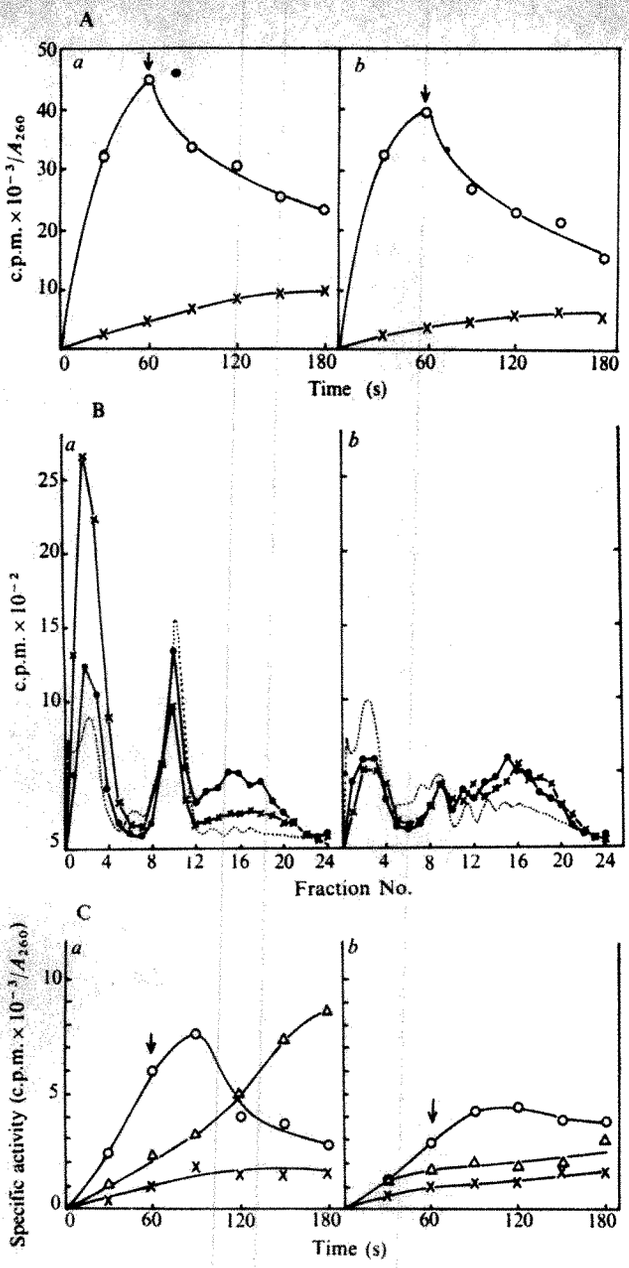

FIG. 3 Pulse labelling of proteins in amino acid-starved cells of both CP78 (*rel*⁺) and CP79 (*rel*⁻). A 60 ml culture, grown to log phase under the supply of twenty amino acids, was washed and resuspended in a glucose (0.4%)-M9 minimal medium without addition of any amino acid. After starvation for 15 min at 28°C, 10 μCi each of radioactive amino acids mixture (8.7 Ci mmol⁻¹ ³H-L-phenylalanine (G), 28.7 Ci nmol⁻¹ ³H-L-lysine-4,5 and 42 Ci mmol⁻¹ ³H-L-tyrosine-3,5 was added. After 60 s of labelling, unlabelled phenylalanine, lysine and tyrosine were added to the final concentration of 25 μM each. At 30 s intervals 10 ml portions of the culture were poured over ice containing 1 mg of chloramphenicol. The cell lysates were prepared and analysed by sucrose density gradients as in Fig. 2. For the determination of radio-activity, 0.2 ml fractions of the gradient were collected and precipitated with 2.5 ml of cold 4% perchloric acid. They were then filtered on Whatman GF83 glass filter papers, washed with 0.4% perchloric acid, 50% ethanol and dried. Radioactivity was determined by scintillation counting in a toulene-based mixture. *a*, CP78 (*rel*⁺); *b*, CP79 (*rel*⁻). *A*, Incorporation of radioactive amino-acids into cell lysate and its acid-insoluble fraction. The arrow indicates the time when unlabelled amino-acids were added. ○, Lysates were applied directly to glass filter papers, dried and counted; ×, lysates were precipitated with cold 4% perchloric acid and counted as described above. *B*, Sucrose density gradient pattern of incorporation. Dotted line shows optical density. ●, The radioactivities were chased for 30 s by addition of unlabelled amino acids after labelling with ³H-amino-acids for 60 s; ×, chased for 90 s. *C*, Release of radioactive polypeptides from polysomes to supernatant fraction. Specific activities of each fraction of polysome, ribosome and supernatant were calculated from the patterns of sucrose density gradients, which denote total counts of corresponding region per total A_{260} unit of that region. The arrow indicates the time when unlabelled amino acids were added. ○, Radioactivities in polysome region; ×, ribosome region; △, supernatant region.

The above results are consistent with those obtained from polysome turnover experiments. Thus, the translational defect in *rel*⁻ cells under the restriction of amino acid supply may be located in some processes involving ribosomal functions.

Many studies have been reported on the mechanism of induction or derepression of enzymes in bacteria. In most cases, the induction or derepression of enzymes is achieved by the regulation at the level of transcription, and the mechanism involved in this process is largely understood. The mechanism of translational control in enzyme formation during adaptation has not yet however been clarified.

From the study on the formation of β-galactosidase in amino acid-starved cells of *Salmonella typhimurium*, Engbæk *et al.*[21] have pointed out that a mechanism for successful use of a limiting supply of aminoacyl-tRNA must exist in the cells. We consider that the *rel* gene is responsible for this mechanism. As we have shown before[2], the mutation in the *rel* gene causes the impairment of formation of enzymes when the supply of amino acid is limited. We have observed that polysome turnover is suppressed in *rel*⁻ cells under amino acid starvation, whereas in *rel*⁺ cells polysomes actively turn over and the polypeptides synthesised on polysomes are transferred normally to the supernatant fraction. These results lend additional support to the view that *rel* gene product functions at the translational level during amino acid starvation. Hall and Gallant[22] have also found that an abnormal β-galactosidase with reduced specific enzymic activity and increased thermolability is formed in amino acid-starved *rel*⁻ cells.

Pedersen *et al.*[23] and Haseltine and Block[24] have reported that ppGpp and pppGpp, the compounds which accumulate in response to amino acid starvation in *rel*⁺ cells, are synthesised on ribosomes in a cell-free system of *E. coli*. The synthesis requires the presence of messenger RNA, deacylated tRNA, and a protein factor isolated from the ribosomal washing of *rel*⁺ cells[25]. Their results suggest that ppGpp and pppGpp are formed on polysomes, when deacylated tRNA is bound to the A site of ribosomes due to the unavailability of the appropriate aminoacyl-tRNA species.

As is shown here, polysomes in *rel*⁺ cells are able to continue to synthesise proteins after amino acid deprivation whereas in *rel*⁻ cells the movement of polysomes is inhibited. It would be of interest to examine whether there is any close correlation between the formation of the unusual guanine nucleotides and the successful use of limiting amount of aminoacyl-tRNA during deprivation of amino acids.

Selective pressure on HL-A polymorphism

THE advantages of heterozygotes is one of the most frequent explanations of the maintenance of a polymorphism. This advantage may have the form of a lower fitness of all homozygotes, whatever the allele they possess. According to observations on a small Tuareg isolate, such is apparently the case for the polymorphism of the histocompatibility system HL-A.

The HL-A system (human leukocyte antigen A) is immunologically detected by means of specific sera. It depends on two loci which lie close together on the same chromosome. At the present time (including the blanks), 15 alleles are well defined at the first locus (SD1) and 20 alleles at the second (SD2). Each combination of one allele at the first locus and one at the second is called a 'haplotype'. The number of these combinations is therefore 300. Because of the low recombination fraction between the loci (about 0.008) (ref. 1), the system can, for certain purposes, be considered as a single locus system with 300 alleles.

Homozygotes (having two identical haplotypes) are very rare since all the haplotypes have a lower frequency than 10% in Caucasoid populations. It is pointless to try to show a discrepancy between the observed frequency of homozygotes and that expected in a Hardy-Weinberg equilibrium. The only exception is in very small, isolated populations in which, because of founder effect or genetic drift, the number of haplotypes present in the genetic makeup of the group is greatly reduced.

This is the case with the Kel Kummer Tuareg tribe, of the South Sahara. This tribe was founded in the seventeenth century, since when it has lived entirely apart from surrounding populations and has rigorously respected the very strict rules of mating which require marriage with the mother's brother's daughter. At present it numbers about 300 people.

The genealogies, collected by A. Chaventré[2] give an exhaustive description of the descent of the tribe, and some of the process of transmission of the genetic heritage through three centuries. They cover a total of 2,500 individuals, and an example of such a genealogy is shown in Fig. 1.

These genealogies gathered from oral tradition, have been confirmed by many cross checks with written records (military registers and accounts of travellers), systematic research on paternity exclusion and research on common ancestors of individuals with rare genes. These verifications have shown the genealogical information to be reliable. The 2,500 individuals, dead or living, of the tribe all descend from a few ancestors, with extremely intricate lines of descent.

This inbreeding may be measured by the classical F coefficient[3]. It is possible to calculate the F values by computer taking into account all the possible paths between living individuals and their common ancestors (in some cases the number of paths is about 10^6). For the set of 106 individuals whose HL-A genotype is known, the mean of the computed F coefficients is 0.1108, which is extremely high. In two sibships it is even greater than 0.24 ($F = 0.25$ for offspring of sib-mating).

The homogeneity that results from this inbreeding is better shown by taking the 'probabilities of a gene's origin', that is, the set of probabilities that, for the various founders, a gene taken at random in the population is derived from him, where a 'founder' is an ancestor whose parents are unknown[3].

Classifying the 97 founders in order of decreasing importance, we obtain Table 1. This shows that 90% of the genetic makeup of the tribe comes from only 22 individuals. These individuals represent 44 haploid sets, some of which are probably identical since the founders certainly were related (but in a way we do not know). It is therefore evident that the Kel Kummer Tribe exhibits an uncommon genetic homogeneity.

To discover the HL-A genetic structure of the Kel Kummer tribe we tested for antigens: HLA1, 2, 3, 9, 10, 11, W29, W30+31 and W28 for the first locus (SD1), and HLA5, 7, 8, 12, 13, W5, W10, W14, W15, W17, W18, W21, W22, W27 and DA(6) for the second locus (SD2). The research[4,5] on the HL-A antigens of the Kel Kummer have shown that they possess only 21 haplotypes, two of which exist at high frequencies, namely: HL-A11/W21, 19%; W28/HL-A7, 17%.

Among the 106 individuals whose genotypes (the two haplotypes) are known, only one is a possible homozygote; but this cannot be ascertained since he may have a blank allele at both loci; a study of his genealogy gives the probability 0.50 of homozygosity.

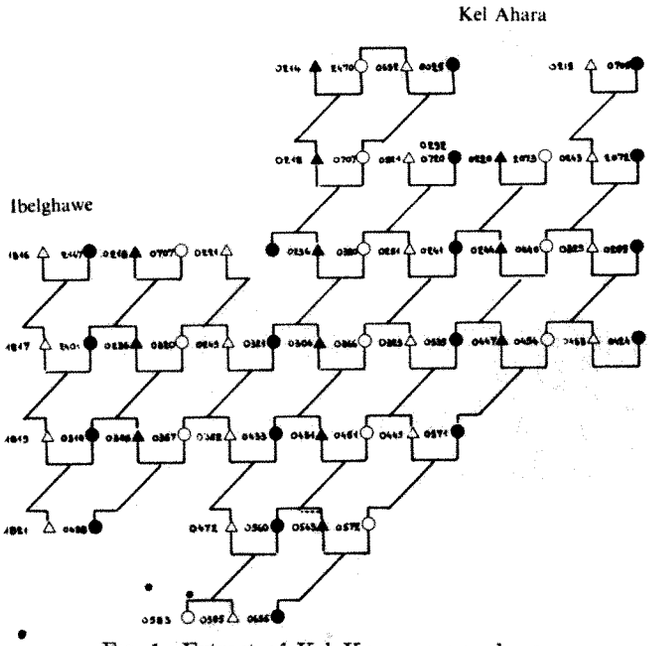

FIG. 1 Extract of Kel Kummer genealogy.

TABLE 1 Genetic make-up of the Kel Kummer tribe

Founder No.	Proportion of the genetic make-up (%)	Cumulative
1	10.6	
2–7	41.8	52.4
8–12	19.4	71.8
13–22	17.4	89.3
23–97	10.7	100

The number of homozygotes we expected is, however, significantly higher. If the population were in Hardy-Weinberg equilibrium for the HL-A loci, the total frequency of homozygotes, equal to the sum Σp_i^2 of the haplotypes' squared frequencies, would be 8.4%. Moreover we have seen that the rules of choice of mate are very strict and so the prohibition of sib-mating, which entails a small 'negative inbreeding', is largely counterbalanced by the preference for cousin mating (30% of the marriages) or for mating with a cousin once removed (15%). The mating behaviour for the whole tribe corresponds to a deviation from random mating measured by the δ coefficient[3], such that $\delta = + 0.01$. The frequency of homozygotes, knowing the present genetic structure and the mating behaviour should therefore be

$$h = \delta + (1 - \delta)\ \Sigma p_i^2 = 9.3\%$$

Under the hypothesis that the observed sample is a random sample, the expected number of homozygotes among the 106 tested individuals, is a random variable with expected value $E = 106 \times 0.093 = 9.86$ and standard deviation $\sigma = (106 \times 0.093 \times 0.907) = 2.99$. The observed number (1 or maybe 0) is thus largely outside the confidence interval ($P < 0.005$).

The mean inbreeding coefficient of the tested individuals is $F = 0.1108$. Each of them has therefore a probability of greater than 0.11 of being a homozygote. Because of the non-independence of the genes of the various individuals, one cannot consider the number of individuals with two identical genes as a binomial variable. There is an inconsistency between the expected number of such individuals ($0.1108 \times 106 = 11.7$) and the observed number of homozygotes.

This observation supports the hypothesis that the HL-A chromosome segment is maintained in a polymorphic condition by disadvantages to being a homozygote, whatever genes are possessed. A model of this kind has been proposed for the histocompatibility systems[6], but has not previously been supported by observation. The present data do not enable the role of HL-A system itself to be distinguished from that of a linked locus. It is probable however that HL-A antigens are present, in the haploid state, on the spermatozoa[7]: however, no disturbance on zygotic assortment for the HL-A system has been found in family studies[8,9].

Finally we note that the genes of the main system of histocompatibility, HL-A, are located on a chromosome segment which is very important for many immunological processes (locus of mixed lymphocyte culture, MLC, and probably locus of immune response, Ir). The detection of the presence of foreign cells (alloimmunisation) depends mainly of this segment; it is possible that it includes 'archaic' loci, which have remained unchanged during evolution, together with duplicated loci which have become more and more sophisticated. In plants there exist loci for detection of foreign cells, the 'self-sterility systems', which prohibit homozygous fertilisation and maintain polymorphism. It is possible that such genes still exist in man on the alloimmunisation chromosome segment, contributing to the maintenance of polymorphism. This interpretation of our observations is supported by the following argument: when non-related parents share the same allele for HL-A or for MLC loci, the offspring is homozygote with a frequency close to the expected proportion[10]; consequently the 'prohibition of homozygote' we have observed may correspond to a locus closely linked to HL-A but which is not HL-A itself nor MLC.

This homozygous deficit has not, however been found in studies of other relatively isolated populations[11]. This leads us to believe that the gene preventing homozygosity (which is not HL-A) may be at some distance from the HL-A loci on this chromosome. Nevertheless in the Tuareg tribe, which is extremely inbred, it is always transmitted with the HL-A loci because of the limited recombination opportunities. Another theory would be that the locus linked to HL-A possesses several alleles, not one of which allows homozygosity. This has been proven to be the case of T locus in mice which is linked to the major histocompatibility locus (H-2).

Stimulation of bone marrow haemopoietic stem cells by a factor from activated T cells

I present here direct evidence that a factor(s) produced by activated thymus-derived lymphocytes (T cells) enhances proliferation of pluripotent bone marrow stem cells.

T cells have been known as a source of humoral mediators which can regulate (enhance or inhibit) antibody response[1–5]. These mediators are released when T cells are stimulated with an antigen[6–9] or with mitogens (phytohaemagglutin (PHA) or concanavalin A) although direct evidence for the latter is not available[10]. With one exception[9], the effect of the mediator was reported to be non-specific, that is, factor that was induced by one antigen stimulated production of antibody to another non-cross-reacting antigen[6–8]. This implies that the factor stimulates proliferation and differentiation of immunocompetent bone-marrow-derived cells (B cells) in general.

TABLE 1 Activation of splenic haemopoietic c.f.u. by PHA *in vitro* and *in vivo*

Source of spleen cells	PHA*	Recipient mice: No. cells† injected, × 10^5	Recipient mice: c.f.u. per spleen‡, individual mice	c.f.u. per 10^6 injected cells (fresh or cultured)	^{3}H-thymidine pulse§ (d.p.m. per 10^6 cells)
Fresh suspension					
normal donors	−	2.0	3,3,4,4,5	19.0 (15–25)¶	
PHA-injected donors	+	2.0	9,12,13,14,15	63.0 (45–75)	
Cell culture	−	15.0	0,0,0,0,1,2,2,2,3	≤1.0 (<1–2)	1,950 (1,900–2,000)Φ
	+	10.0	2,2,3,3,3,3,4,7	3.4 (2–7)	117,500 (94,300–144,000)

Male Balb/c mice (Jackson Laboratory) were both donors (6–8 weeks old) and recipients (10–12 weeks old). Recipients received an X-ray dose of 700 rad (180 kV, 15 mA, 80 rad min^{-1}, with 2 mm Al and half-value layer 0.5 mm Cu, distance 51 cm) 6 h before cell transfer. A cell suspension (pooled from several donors) was prepared by pressing spleens through stainless steel wire screens in cold Puck's saline with antibiotics, followed by washing. Eagle's minimal essential medium was used for suspension cultures, containing 1% non-essential amino acids (100x), 2mM L-glutamine, lmM sodium pyruvate, 1% antibiotic mixture (100x) and 5% foetal calf serum. Cultures (2–3 ml, 10^7 cells per ml), in disposable tissue culture tubes, (Falcon No. 2051) were kept for 3 d at 37°C in air with 5% CO_2. Cells were then washed and injected into irradiated recipients in the numbers indicated. PHA was added at a concentration of 2.5 μg ml^{-1} of medium, at the beginning of cultivation. For *in vivo* experiments, donor mice were injected with 200 μg intraperitoneally 24 h before cell transfer.

† Nucleated cells (viability determined by trypan blue exclusion).

‡ c.f.u. is the number of macroscopic colonies visible on spleen surface 8 d after cell transfer. Colonies were counted using magnifying glasses (10x) after brief immersion of the spleen into acetic acid-ethanol (1:4). No colonies were found in spleens of control irradiated recipients which receive no cell inoculum.

§ Pulse labelling was done in 2 ml cultures containing 10^6 cells per ml of the medium with or without PHA (0.5 μg ml^{-1}). ^{3}H-thymidine (2.5 μ Ci ml^{-1} of culture) was added for 24 h between the second and third days of cultivation. Cells were then precipitated and washed with 0.2 N perchloric acid, the pellet resuspended in 0.1 N NaOH, aliquots (0.1 ml) pipetted into scintillation vials with 10 ml of Aquasol (New England Nuclear Corp.) and radioactivity determined in a Packard scintillation counter.

¶ Average number of c.f.u. per 10^6 of injected cells (range within the group).

Φ Mean of duplicates (range).

An obvious question arises. Is the effect of activated T cell factor(s) limited to the functionally specialised immunocompetent B cells, or could it also stimulate other bone marrow-derived cells and bone marrow cells? Precursors of antibody-forming cells represent only part of the bone marrow population; another large portion comprises undifferentiated stem cells, or cells engaged in haemopoiesis (erythropoiesis and granulopoiesis).

The answer was sought as follows. Activated T cells were obtained from cultures of spleen cells incubated with phytohaemagglutinin (PHA). The stimulatory effect of PHA was measured by pulse labelling with ^{3}H-thymidine. Haemopoietic stem cells were enumerated by the colony-forming unit (c.f.u.) assay[11]. A sample of the cultivated cell suspension in which the stem cells (c.f.u.) were to be detected, was injected into lethally irradiated syngeneic mice. Spleens of recipients were removed 8 d later and macroscopic colonies on their surface were counted. Each colony is a clone arising from a single pluripotent haemopoietic stem cell and contains cells of the same morphological character, either erythrocytic, megakaryocytic or granulocytic[11–14]. No lymphocytic colonies have been reported so far, even in spleens of mice that received cells from PHA-stimulated donors[15]. Colony-forming stem cells can be obtained from bone marrow, spleen, blood and lymph nodes (in decreasing order of frequency) but not from thymus or thoracic duct cells[15–18].

In my first experiment, normal spleen cells were cultivated *in vitro* for 3 d with or without PHA (2.5 μ ml^{-1}) and c.f.u. in the cultures was counted by the transfer of 10^6 cells to irradiated recipients. To verify that the tissue culture reflected the effect of PHA *in vivo*[15] some irradiated recipients were given freshly isolated spleen cells (10^5 to 10^6) of either normal donors or doners injected with PHA 1 d before the transfer. Table 1 shows that stimulation of spleen cells with PHA, either *in vivo* or *in vitro*, increased the number of haemopoietic cells (c.f.u) about three times ($P < 0.01$, by Wilcoxon's unpaired rank test, ref. 19).

The following experiments were performed to determine if the effect of PHA on stem cells is mediated by T cells. Spleen cells were treated either with anti-theta serum plus complement to eliminate T cells, or with normal serum and complement as a control. The cells were washed and cultured for 3 d with or without PHA. c.f.u. were enumerated as previously. Table 2 shows that the stimulation of DNA synthesis and the increase of stem cells (c.f.u.) observed in control cultures (containing T cells) ($P < 0.01$) did not occur in experimental cultures in which T cells were eliminated ($P > 0.05$).

To show that the effect of T cells on c.f.u. is mediated by a factor(s), supernatant fluids from previously described cultures were collected, filtered through 0.45 μm Millipore filters and stored frozen at −20° C. They were then tested

TABLE 2 Role of theta-positive cells (T cells) in increase of splenic colony-forming cells in cultures stimulated with PHA

Cell treatment before culture	PHA*	Recipient mice: No. cells† injected, × 10^5	Recipient mice: c.f.u. per spleen, individual‡	c.f.u. per 10^6 injected cells	^{3}H-thymidine pulse§ (d.p.m. per 10^6 cells)
Normal serum + C′	−	9.0	0,1,1,1,1,2,2,2	1.4 (<1–2)¶	2,955 (2,850–3,080)‖
	+	4.5	1,1,3,3,3,4,5	6.3 (2–11)	103,750 (103,500–104,000)
Anti-theta serum + C′	−	7.2	2,3,3,3,4,5,7,9,9	6.9 (3–12)	2,460 (2,360–2,560)
	+	6.3	2,3,3,5,5,9	7.1 (3–14)	2,310 (1,830–2,790)

Anti-theta serum was prepared by AKR mice given ten weekly injections of C3H thymocytes (10^7 cells per injection, intraperitoneally). 100 μg of a pertussis vaccine (gift from the Massachusetts State Laboratory) was given with the eighth injection. The serum was specific for thymus cells (titre 1:8,000) and killed 40–50% of spleen cells as determined by trypan blue exclusion. Normal guinea pig serum absorbed twice with mouse spleen and liver cells (5:1, v/v) was used as a source of complement (C′). Freshly isolated spleen cells were incubated, under sterile conditions, with anti-theta serum (5 × 10^7 cells per ml of Puck's saline, final dilution of antiserum 1:10) in a water bath at 37°C for 20 min. Guinea pig serum was then added as a source of complement (1:10) and left for another 20 min. Normal mouse serum (absorbed) served as a control. Cells were washed in Puck's saline and cultivated for 3 d as described in Table 1. As anticipated, specific killing of T cells resulted in a relative increase of c.f.u. per 10^6 viable cells remaining in the spleen cell suspension. The increase was expected to be two-fold but was actually higher (compare first and third row in Table 2). The possible stimulating effect of antigen-antibody complex on CFU might be considered.

Footnotes are explained in the legend to Table 1.

TABLE 3 Stimulation of bone marrow c.f.u. with a T cell product *in vitro*

Experiment	Culture medium	Recipients: No. cells† injected, × 10^5	Recipients: c.f.u. per spleen, individual‡	c.f.u. per 10^6 injected cells	^{3}H-thymidine pulse§ (d.p.m. per 10^6 cells)
A	MEM	4.3	3,3,4,4,5,6,6	10.0 (7–14)	10,500 (9,600–11,500)
	MEM + PHA	4.5	4,4,4,5,5,5,6,6	11.0 (9–13)	7,500 (7,500–7,500)
	S_{MEM} 1:20	8.4	4,5,6,6	6.4 (5–7)	12,300 (11,200–13,400)
		16.8	9,9,10		
	S_{PHA} 1:20	4.0	6,7,8,10	20.0 (15–24)	31,450 (31,300–31,600)
		8.0	14,14,16,19		
B	S_{MEM} 1:50	2.5	1,2,2,3,3,4	10.0 (4–16)	12,950 (11,200–14,700)
	S_{PHA} 1:50	2.5	10,10,12,14,15,18	53.0 (40–72)	31,000 (28,000–34,000)
	1:100	2.5	3,4,4,5,6,9	21.0 (12–36)	27,400 (24,000–31,000)
	$S_{anti\text{-}theta.MEM}$	2.5	3,4,4,4,5	16.0 (12–20)	15,500 (13,000–18,000)
	$S_{anti\text{-}theta.PHA}$	2.5	2,2,2,3,3,4,4,5,5	14.0 (8–20)	18,000 (16,000–22,000)

Bone marrow cells (pooled from several donors) were flushed from femurs with cold Puck's saline, washed and resuspended in the culture medium as described in Table 1. Supernatant fluids added to the medium at various concentrations were collected, in previous experiments, from 3-d cultures of spleen cells in the medium without (S_{MEM}) or with (S_{PHA}) PHA. Supernatants added in experiments *A* and *B* came from two different experiments in which the stimulating effect of PHA on splenic c.f.u. in the cultures was determined. '$S_{anti\text{-}theta.MEM}$' and '$S_{anti\text{-}theta.PHA}$' are supernatants from cultures shown in Table 2 (third and fourth row) in which spleen cells were pretreated with anti-theta serum plus C′ and then cultured with or without PHA in the medium. Splenic B cells (obtained by treatment of spleen cell suspension with anti-theta serum and complement before cultivation) were also used as the target for the factor. Results (unpublished) were comparable to those reported here with bone marrow cells.

MEM, minimal essential medium.

Footnotes are explained in the legend to Table 1.

for the presence of a cell-free substance able to stimulate haemopoietic stem cells *in vitro*. Bone marrow cells (which do not respond to PHA), rather than spleen cells, were the source of c.f.u. and the target for the hypothetical factor. This eliminated the possibility of stimulation of T cells by trace amounts of PHA in the supernatant fluids. Bone marrow cells were flushed from femurs of normal donors, washed and resuspended in the culture medium containing various concentrations of either control supernatants from normal, untreated spleen cultures (S_{MEM}) or active supernatants from cells cultured with PHA(S_{PHA}). Another set of control cultures included bone marrow cells with or without PHA in the medium. Cells were tested for the number of c.f.u. after 24 h of cultivation. Some culture tubes were kept for 3 d and were pulse-labelled with ^{3}H-thymidine.

PHA failed to stimulate DNA synthesis and c.f.u. ($P > 0.05$) in bone marrow cell cultures (Table 3, experiment *A*). In contrast, the presence of S_{PHA} in the culture medium increased DNA synthesis in cultures and increased the number of active c.f.u. two to three times compared with control cultures containing S_{MEM} (experiments *A* and *B*). The factor was active up to a dilution of 1:100 in the medium with an optimum concentration of about 1:50. Supernantant fluid from spleen cells pre-treated with anti-theta serum plus complement and then cultured with PHA did not contain any stimulatory activity ($P > 0.05$).

It can be stated that mouse splenic T cells activated with PHA *in vitro* release a substance(s) which can stimulate proliferation of bone marrow cells and activate haemopoietic stem cells *in vitro* and *in vivo*. The possibility of such a mediator was implied by previous observations that the administration of thymus-dependent antigens changed considerably the frequency of haemopoietic stem cells in blood and spleen[20–21]. A similar effect was observed by Micklem[15] after *in vivo* injection of PHA, a specific mitogen of mouse T cells[22–25]. My results provide direct proof of existence of such a factor(s).

The chemical nature of this T cell product is not known. I suggest, however, that it is related to immunoregulating factors induced in T cells by antigen[6–9] rather than to 'thymosine', a soluble substance obtained from normal thymus cells and able to promote immunological maturation of B cells[26–32]. The suggestion is based on the observation that the factor described here can be obtained from stimulated peripheral T cells only. Thymus cells, either normal or incubated with PHA, do not release an active substance that has this effect on stem cells (unpublished results of E. B. Waner and myself).

If upheld, my observations will offer a mechanism by which activated T cells can regulate not only antibody formation in specialised immunocompetent cells, as described by others, but also differentiation of more primitive stem cells and haemopoietic cells in bone marrow. This model will provide another test for comparative analysis of biological functions of humoral products from T cells.

I thank Ms E. B. Waner for technical assistance and Dr F. Modabber, Department of Microbiology, Harvard School of Public Health, for stimulating discussions and help in preparation of the manuscript. This work was supported by a grant from the American Cancer Society.

Animal longevity and protein turnover rate

THE life spans of various mammalian species differ but the biochemical mechanism of this regularity is unknown. In our opinion there is a sufficient amount of experimental data to solve this problem. We refer to the data presented in twelve investigations by different authors collated into one table (Table 1), and the data of the two works collated in another (Table 2)[1]. In these, the data on the protein plasma turnover for various species of mammals is presented. We have added a column on the maximum life span of the species[2] into each table.

Table 1 shows that the highest rate of protein turnover is observed in the rat, it is lower in the dog, and still lower in human beings. Table 2 shows that the small animals, such as mice, guinea pigs or rabbits, have the highest rate of turnover, and the turnover is lower for dogs, and still lower for cows, monkeys and human beings.

In terms of a life span there is a negative correlation between the longevity of animals and their protein turnover rate. The existence of such a regularity has attracted no attention so far. The protein turnover rate, however, does characterise the intensity of protein synthesis, and this in turn, depends on the intensity of DNA activity.

TABLE 2 Turnover of homologous proteins of various species labelled with ^{131}I (ref. 1, column reference indicates 262 and 263).

Species	Albumins: Time interval (d)	Albumins: Halflife (d)	γ globulin: Time interval (d)	γ globulin: Halflife (d)	Maximum lifespan (yr)
Human	7–28	15.0	4–21	13.1	110–115
Cow	2–30	20.7	6–27	21.2	20*
Monkey			4–24	6.6	30

Solubilisation of angiotensin II receptors in rabbit aortae membranes

HORMONE–RECEPTOR interaction is the first step of a chain of cellular processes leading to the hormonal response. Receptor sites are believed to be macromolecular components finite in number, possessing a genetically determined structure and capable of specific recognition and interaction with hormones with a high degree of specificity and affinity. Receptors of steroid hormones are intracellular, whereas those of neurotransmitters and polypeptide hormones are located in the cell membranes[1].

Angiotensin II is a polypeptide hormone which has, among many pharmacological actions, the basic property to contract smooth muscles[2]. The availability of a ^{3}H-angiotensin II having a high specific activity and possessing the full biological activity of the native hormone[3] allowed us to demonstrate the presence of angiotensin receptors in the intact rabbit aorta[4], in the microsomal membranes extracted from homogenates of intimal medial layers of rabbit aortate[5], and in a membrane fraction derived from the plasma membrane[6]. At the various levels of purification the binding sites were considered as hormone receptors, as the kinetic constants of angiotensin binding were identical to those of the biological responses induced by the hormone.

Here we describe the solubilisation of the above described angiotensin-binding components of smooth muscle cells of rabbit aorta, and provide some information about the molecular conformation of angiotensin required for its interaction with receptors.

The microsomal membranes were extracted from homogenates of intima media of rabbit aortae by differential centrifugation[7]. These membranes were considered to be essentially derived from smooth muscle cells because the contribution of intima was less than 1% total mass. Receptors were solubilised by suspending the 100,000*g* microsomal pellet in 50 mM Tris-HCl buffer, *p*H 8.0, containing 100 mM NaCl and deoxycholate (7-deoxycholic acid, Sigma; final concentration 0.2–1.0%). The membrane protein concentration[8] was 4.6 mg ml^{-1}. After a 30 min incubation at 0°C, the membrane suspensions were centrifuged for 1 h at 200,000*g* and the resulting soluble supernatants were assayed for angiotensin binding. After incubation of soluble material with ^{3}H-angiotensin II (specific activity 40 Ci mmol^{-1}), aliquots

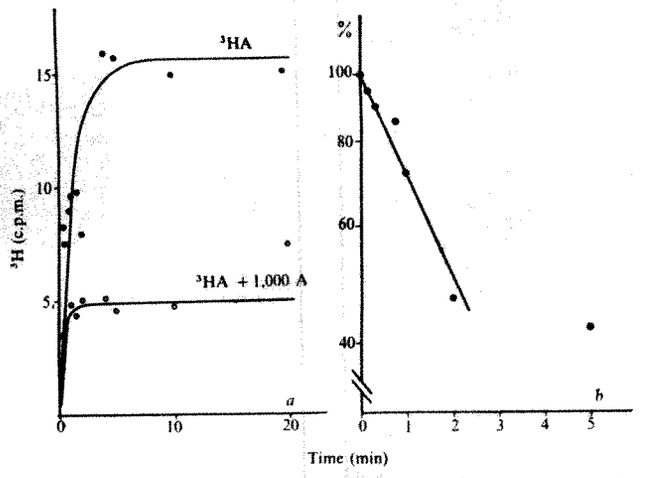

FIG. 1 *a*, Time course of binding of 2.5 × 10^{-8} M of ^{3}H-angiotensin II to solubilised material at 29° C in the absence (^{3}HA) and presence of 1000-fold excess of unlabelled angiotensin (^{3}HA + 1000 A) Results expressed as c.p.m. mg^{-1} (×10^3); *b*, displacement of bound radioactivity induced by addition of 1000-fold excess of unlabelled angiotensin to solubilised material after its incubation with 2.5 × 10^{-8} M of ^{3}H-angiotensin II for 5 min at 29° C. Results are expressed in % of bound radioactivity.

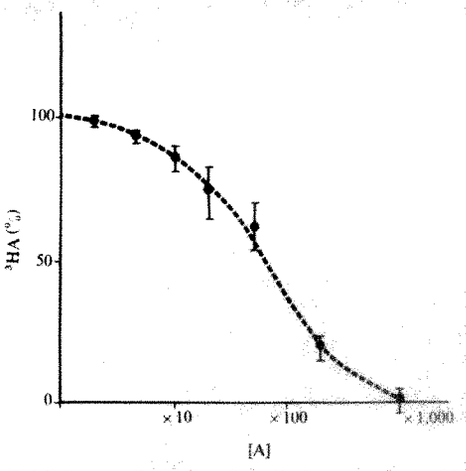

FIG. 2 Inhibitory effect of unlabelled angiotensin II (A) on the binding of 2.5 × 10^{-8} M of ^{3}H-angiotensin II to solubilised material. The various concentrations of unlabelled angiotensin II are indicated on the abscissa (10, 100 and 1000-fold excess compared to the ^{3}H-angiotensin II concentration). ^{3}H-angiotensin II and unlabelled angiotensin II were added simultaneously to the incubation mixture. The nonspecific binding (40% of bound radioactivity) was subtracted from each experimental value. ⧫, the mean and s.d. of 2–15 experiments.

(400 μl) of reaction mixture were placed on the surface of G-50 fine Sephadex columns (14.0 × 0.6 cm) equilibrated and run at 4°C with 50 mM Tris-HCl buffer *p*H 8.0 with or without deoxycholate. The eluates were added to scintillation fluid and counted in a liquid scintillation spectrometer. The validity of Sephadex for the separation of bound and free ^{3}H-angiotensin II was demonstrated in control experiments performed with buffer alone, showing that only 0.01% of ^{3}H-angiotensin II appeared in the void volume. Each experimental sample was corrected for the radioactivity appearing in the void volume in the control.

Treatment of microsomal membranes by deoxycholate solubilised 50% of membrane proteins and solubilisation was maximal at concentrations of deoxycholate greater than 0.2%. After treatment with deoxycholate 80% of the specific binding of ^{3}H-angiotensin II was recovered in the soluble supernatant and 20% in the pellet. The binding of ^{3}H-angiotensin to the solubilised material is proportional to the concentration of protein. Time course studies and concentration-dependent binding curves of ^{3}H-angiotensin II were performed in the presence and absence of 1000-fold excess of unlabelled angiotensin II. The specific binding is considered as the difference between the binding of ^{3}H-angiotensin II measured in the absence of unlabelled angiotensin.

The specific binding of ^{3}H-angiotensin II to the solubilised material reached equilibrium within 5 min at 29°C (Fig. 1). No significant specific binding was observed after 90 min of incubation at 4°C; in contrast the non specific binding was minimally affected by changes in temperature. The association rate constant at 29°C is $K_1 = 2.5 \times 10^5$ mol^{-1} s^{-1}. Dissociation of angiotensin–receptor complex was studied by adding 1000-fold excess native angiotensin to the samples preincubated for 5 min at 29°C with 2.5 × 10^{-8}M of ^{3}H-angiotensin II. The samples were then incubated for varying periods before being assayed for specific angiotensin binding. During the first 2 min dissociation of the ^{3}H-angiotensin binding was a first order kinetic reaction, the rate constant of which being $K_{-1} = 4.1 \times 10^{-3}$ s^{-1} (Fig. 1). A Scatchard plot[9] of the specific binding of ^{3}H-angiotensin II to the deoxycholate-solubilised proteins indicates that a single high affinity receptor site is apparently being measured with ^{3}H-angiotensin II concentrations varying from 2.5 × 10^{-9} M to 10^{-7} M. The number of specific binding sites is 2 pmol per mg of protein, and the apparent dissociation constant

The concentrations of ^{3}H-angiotensin II and other drugs were 2.5×10^{-7}M and 5×10^{-7}M, respectively. Conditions of incubation and expressions of results are as in Fig. 2. For each compound, six determinations of ability to compete were made. The elucidation of the structure of angiotensin derivatives has been detailed[15,16]. Data obtained on membranes are from ref. 6.

calculated from the slope of the plot is K_d 29°C $\sim 2.0 \times 10^{-8}$ M. The specificity of the angiotensin binding to the solubilised material was assessed by displacement experiments shown in Fig. 2 and Table 1.

The membraneous hormone receptors which have already been solubilised and partially characterised are those for insulin in liver and fat cells[10], for catecholamines in myocardium[11] and turkey erythrocytes[12], and for acetylcholine in the electric tissue of fish[13]. That the angiotensin receptors of the rabbit aorta smooth muscle membranes were solubilised as described here is supported by several lines of evidence: first, the kinetic constants of ^{3}H-angiotensin II binding obtained in our previous studies on intact aorta and microsomal membranes are similar to those measured on solubilised material (Table 2). These kinetic constants are very close to the kinetic constants of the biological response elicited by angiotensin, that is contraction of intact aorta[4] and release of calcium from microsomes[5,14]. It seems therefore that the binding sites of angiotensin may be considered as the major elements of the receptors responsible for the induction of the biological response. The binding capacity of the solubilised material is lower than that previously measured on microsomal membranes (Table 2). This is partially explained by the dissociation of the angiotensin–receptor complexes which occurs during chromatography on Sephadex: the amount of bound radioactivity was reduced two-fold by an additional gel filtration. Second, only the specific binding of angiotensin to solubilised material was temperature dependent, indicating that the specific binding process possibly involves a variation of conformation of the ligand and/or the binder, and also indicates the possible participation of hydrophobic groups in the binding process.

Third, solubilised receptor–angiotensin interaction is specific; ^{3}H-angiotensin II binding was only inhibited by native angiotensin II and some angiotensin derivatives. As shown in Table 1 the 2–8 and 3–8 angiotensin fragments had an inhibitory effect on ^{3}H-angiotensin II binding identical to that of the unlabelled angiotensin II; the 1–7, 4–8, 5–8 and 6–8 fragments had a partial inhibitory effect; the 1–6 hexapeptide, which has no biological activity, had no effect. The absence of inhibitory effect to the 1–6 fragment is a strong argument for the specificity of the binding as it shows that the binding of angiotensin to the solubilised material is not related to a nonspecific interaction between some hydrophobic part of the angiotensin molecule and deoxycholate molecules which may remain associated to any of the solubilised membrane proteins.

These results agree with those previously observed on membranes[6]. Fermandjian *et al.*[15,16] have demonstrated that the organisation of the angiotensin molecule in concentrated aqueous solutions and polar organic solvents, such as trifluoroethanol, was that of a cross-β type defined by two turns involving the 3, 4, 5 and 6, 7, 8 amino acids respectively, which was illustrated in our previous publication[6]. The present results indicate that binding to receptor sites does not depend upon the N-terminal as long as the amino acids responsible for the two turns are present. These results also indicate that the C-terminal turn alone allows a partial binding. It seems therefore that the interaction of the peptide with its receptor site requires its organisation in a cross-β conformation which has been shown to stem essentially from the His-Pro sequence (D. Greff, S. F., P. F., M. C. Khosla, R. R. Smeby, and F. M. B., unpublished). These considerations illustrate the extreme similarities of the interactions existing between angiotensin and the solvents which have been used in the physical studies, and those occurring between angiotensin and receptor sites. This demonstrates the validity of the angiotensin model established for such solvents. In addition to the cross-β organisation the Phe^8 is of major importance in the binding process: binding is halved by its removal. The maintenance of full competitive activity with ^{3}H-angiotensin binding when Ile^8 replaces Phe^8 may be ex-

Results on aorta and microsomal membranes are from ref 4 and 5.

plained by the similar hydrophobic properties of both terminal amino acids. In solution, however, the intramolecular interactions promoted by Phe[8] and Ile[8] respectively are somewhat different as observed by circular dichroism (D. Greff, S. F., P. F., M. C. Khosla, R. R. Smeby, and F. M. B., unpublished) which underlines the delicate variations of angiotensin II conformation with the environment.

The comparison of the inhibitory effects of the various angiotensin derivatives on the ^{3}H-angiotensin II binding with their biological activities is difficult because only some of them were tested on isolated rabbit aorta[17]. The marked inhibitory effect on ^{3}H-angiotensin II binding of the competitive antagonist (Ile[8])-angiotensin II agrees with its high affinity for receptor sites of rabbit aorta[18]. The inhibitory effects on ^{3}H-angiotensin II binding of the 1–7, 2–8, 3–8 fragments and of the Phe[4] analogue was expected on the basis that they all have some intrinsic contractile activity. At least for these latter two peptides, whose activities were measured on rabbit aorta[19], it seems that their affinity to receptors as measured in our study is higher than that expected from their contractile effect. This was also observed on isolated membranes[6]. A discrepancy between the binding to receptor sites and the contractile response might be easily explained if the biological response is considered as a complex phenomenon depending both on a good adjustment of angiotension to receptor 'cavity' (which would be, as discussed above, ensured by its cross-β organisation) and the interaction of specialised groups of the molecule with membrane components which would trigger the biological response. This discrepancy might also indicate a great complexity of the receptor site. One might speculate that the binding involves more than one macromolecule and the part concentrated in this preparation is specific for the C-terminal sequence of angiotensin II. It is interesting in this respect to note that in the case of catecholamines the part of the molecule responsible for binding was clearly distinguished from that responsible for the activation of adenyl cyclase[20].

We thank S. Hamon and S. Guichard for typing the manuscript and drawing the figures. This study was supported by the Institut National de la Santé et de la Recherche Médicale, the Centre National de la Recherche Scientifique, and the Délégation Général à la Recherche Scientifique et Technique.

Electrical coupling between afferent nerve terminal and intrafusal muscle fibre in the frog muscle spindle

FROM electronmicroscopic observations, Katz[1] has pointed out the existence of junctions between the afferent nerve terminal bulbs and the intrafusal muscle fibres in frog muscle spindle. It was suggested that the junction might play an important part in the transducing function of the receptor. Here we give physiological evidence for such a role in the simple-type spindle receptors.

Muscle spindles with intact afferent innervation were isolated from the sartorius muscles of Japanese frogs (*Rana nigromaculata*). The isolated spindle was placed at its *in situ* length in a pool of Ringer's solution (111.3 mM NaCl, 1.88 mM KCl, 1.08 mM $CaCl_2$ and 2.38 mM $NaHCO_3$) on a glass plate. The nerve fibre (2–3 cm) was passed into another Ringer's pool through a liquid paraffin pool. The two Ringer's pools were separated by an embankment of vaseline, which in turn was interrupted at its centre by the 1 mm wide paraffin pool. The pools of Ringer's solution were connected to calomel electrodes through Ringer-agar bridges. The potential between a microelectrode, used for recording from the spindle, and the calomel electrode of the same Ringer's pool, was led to a high input-impedance amplifier and displayed on one beam of a dual beam oscilloscope. The potential across the paraffin gap was fed into a high input-impedance differential amplifier and displayed on the other beam of the oscilloscope. Glass microelectrodes (resistance 20–50 MΩ, filled with 3 M KCl or 2 M NaCl) were manipulated under visual control, using an inverted microscope. Constant current stimuli (pulses of 0.05 ms duration or direct current) were given extracellularly to the axon terminal or intracellularly to the intrafusal muscle fibre.

The simple type spindles which were used had normal innervation: the parent axon divides into two myelinated branches; one of them again subdivides into two short myelinated branches, while the other does not[2]. Our experiments concern only the non-subdivided branch and the intrafusal muscle fibre innervated by it. Propagated and abortive spike discharges were defined, as usual[3,4], by recording across the paraffin gap.

Spontaneous spike discharges were recorded extracellularly by a microelectrode in contact with the surface of the nerve terminal. The amplitude was about 1 mV (negative). As the microelectrode was moved away from the nerve terminal in

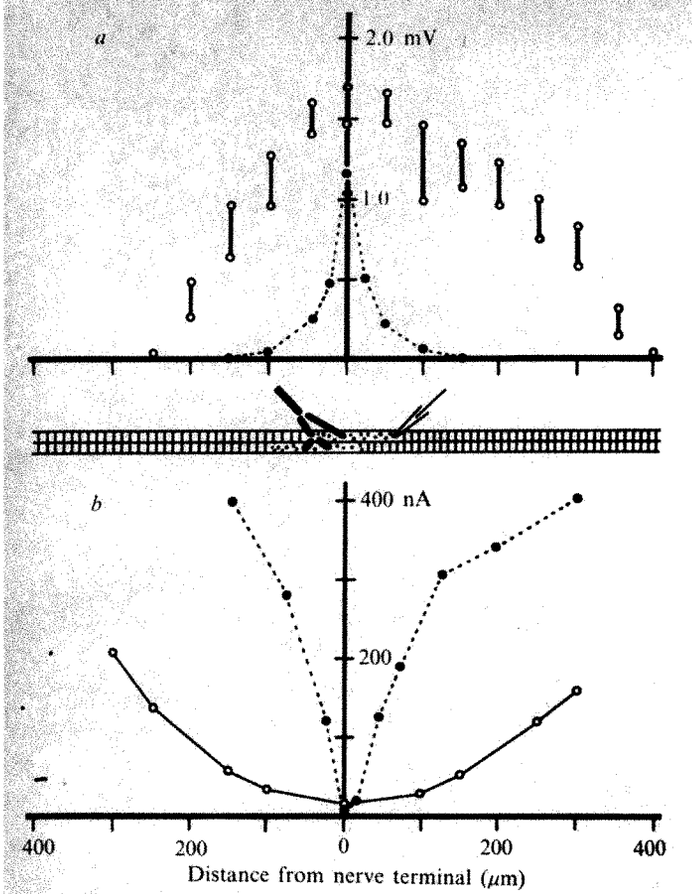

FIG. 1 Decrement of electrical events with increasing distance from nerve terminal. Glass microelectrodes for recording (*a*) and stimulating (*b*) were moved along the longitudinal axis of the intrafusal muscle fibre. ———, Intracellular results; – – – – –, extracellular results. Centre panel shows reticular area (stippled) and polar regions (striated), drawn to scale. *a*, Amplitude of fast potentials recorded from muscle, coincident with spontaneous propagated spikes. Microelectrodes were filled with 3 M KCl for intracellular recording and 2 M NaCl for extracellular recording. *b*, Current strength necessary to excite nerve terminal. Negative pulses were given extra- and intracellularly through glass microelectrodes. Efficacy of positive pulses (data not shown) was about the same.

either direction along the intrafusal muscle fibre, the spike amplitude decreased nearly exponentially, falling to 50% at a distance of 20 μm, and becoming undetectable at a distance of 150 μm from the terminal.

Insertion of the microelectrode into the reticular zone of the intrafusal muscle fibre revealed a resting potential of −50 to −60 mV, and negative spikes which were coincident with the propagated and abortive spikes. These spikes could be recorded intracellularly (solid vertical bars in Fig. 1*a*) at distances as great as 400 μm from the nerve terminal; by that point well-developed striations were present.

These results indicate the existence of a strong coupling between the axon and the intrafusal muscle fibre, allowing fast electrical changes to pass through easily. This coupling seems to have a capacitative component because the above mentioned spikes were transformed as if differentiated (data not shown). Such coupling was also indicated by the following experiments.

Electrical pulses were applied at various points along the surface of the muscle fibre through a microelectrode, and the current intensity necessary to excite the terminal was measured. The dotted line in Fig. 1*b* demonstrates that a negative current pulse of about 2 nA was required at the level of the nerve terminal, and that the current requirement increased steeply with lateral displacement of the stimulating electrode in either direction.

The same experiment was then conducted following penetration of the muscle fibre by the stimulating electrode (solid line in Fig. 1*b*). All stimuli were subthreshold for muscle twitching. When a negative pulse of 3 nA was applied at the level of the nerve terminal, a propagated spike response did occur along the parent axon. No muscle twitching was observed, of course. In sharp contrast to the extracellular stimulation, the current necessary to stimulate the nerve terminal increased only slightly over a longitudinal distance of 100 μm. Even at a distance of 300 μm from the terminal, a pulse of only 150 nA was still sufficient to excite the terminal. Electrical pulses of 100–200 nA, applied intracellularly to the polar region of the intrafusal muscle fibre, occasionally provoked muscle impulses and twitching.

Depolarisation of the intrafusal muscle fibre by means of current injected through an intracellular microelectrode increased the rate of spontaneous afferent discharge, and hyperpolarisation decreased it (Fig. 2). A quasilinear relationship between the current and the discharge rate was obtained in the range of +20 to −20 nA, during which no contraction could be observed. This suggests that the axon terminal may be coupled with the intrafusal muscle fibre by a relatively low resistance.

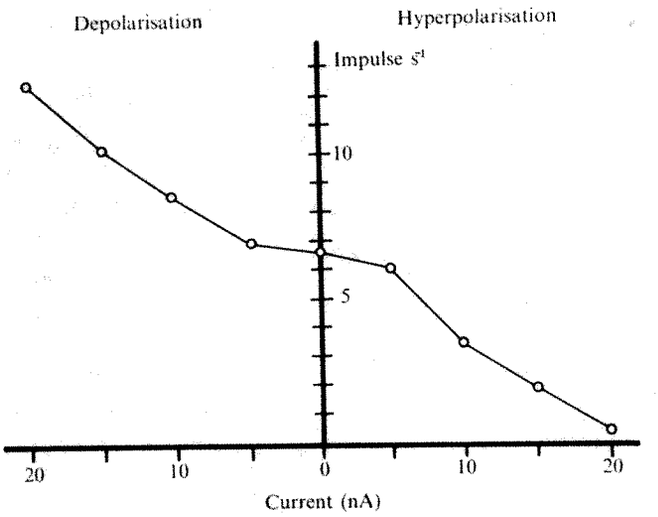

FIG. 2 Effect of direct current injection into muscle fibre upon propagated spike discharge rate of afferent nerve. The microelectrode was inserted into intrafusal muscle fibre 50 μm from nerve terminal.

In the muscle spindle, the afferent nerve terminal and the intrafusal muscle fibre may have electrical coupling through capacitance and resistance, arranged in parallel. Such an electrical coupling must contribute to the transmission of events from the axon terminal to the intrafusal muscle fibre and *vice versa*. It may play an important role in the transduction mechanism of the receptor. It is likely that the sensory nerve terminal is also activated by conducted muscle fibre impulses; it has been found that these 'early discharges' in turn precede the twitch of the intrafusal muscle fibre in mammalian spindles[5,6].

Mouse brain antigen detected by rat anti-C1300 antiserum

THE concept of the cell surface mediating specific cell–cell interactions is pertinent to neurogenesis in which the complex cell interactions known to occur may involve the recognition of specific cell surface components. Characterisation of neuronal cell surfaces is necessary to prove this idea and to elucidate functional mechanisms. Antisera raised against lymphoid cells have provided valuable information on the membrane constituents of lymphoid cells[1–3], and so I have used a similar approach to identify antigenic components expressed on cells of the nervous system of the mouse. The murine neuroblastoma C1300 can, in culture, give rise to cells which display many of the morphological, biochemical, and physiological properties characteristic of neurones[4–6]. Here, I present evidence indicating that rat antisera raised against C1300 tumour cells recognise a tissue antigen which is expressed predominantly on mouse brain.

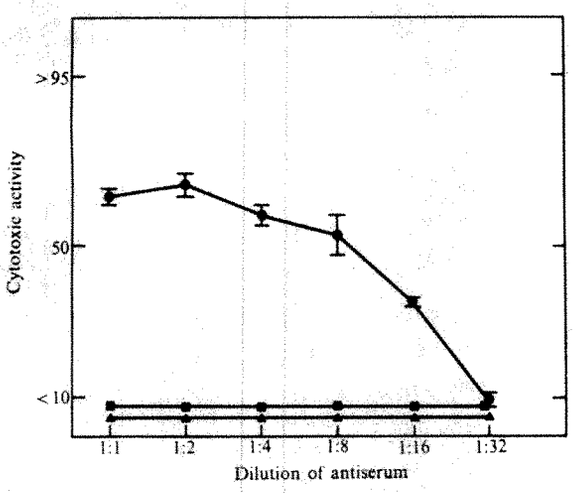

FIG. 1 Titration of rat anti-C1300 antiserum against C1300 tumour cells (●), lymph node cells (LNC) of A mice (■), or LNC of C57 mice (▲). To label the target cells, 0.5 ml of a cell suspension containing 5×10^7 cells ml^{-1} was incubated for 30 min at 37° C with 50 μCi of ^{51}Cr (Na_2CrO_4, Amersham) in medium containing 10% foetal calf serum (FCS). The cells were washed twice and resuspended to 3×10^6 cells ml^{-1} in medium containing FCS. A volume of 20 μl of cell suspension was incubated at room temperature for 30 min with 20 μl of various dilutions of antiserum. The cells were washed with 300 μl of medium and, after centrifugation at 800 r.p.m. for 7 min, the cells were resuspended in 50 μl of a 1:4 dilution of rabbit serum and incubated at room temperature for 30 min. Medium (150 μl) was added and the tubes centrifuged at 1,000 r.p.m. for 10 min. The radioactivity in 100 μl of supernatant from cells exposed to antibody and complement (ab) was measured and compared with that released from cells exposed to detergent (max) or complement alone (comp). Cytotoxic activity was calculated by the formula

$$(ab - comp)/(max - comp) \times 100.$$

In all experiments the absolute release of ^{51}Cr caused by complement was less than 10% of the maximum release. The antiserum tested at a 1:2 dilution in the absence of complement was not toxic. Duplicate or triplicate determinations were made in all cytotoxicity assays.

Although the plateau of maximum cytotoxic activity observed in the ^{51}Cr release cytotoxicity assay was 60% of the amount of ^{51}Cr released by detergent, trypan blue analysis showed that 90%–94% of viable ascites cells were killed by dilutions of antiserum up to 1:4.

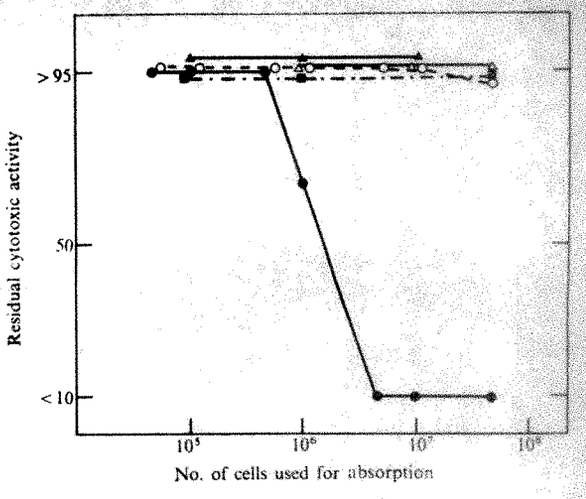

FIG. 2 Residual cytotoxic activity of rat anti-C1300 antiserum after absorption with C1300 ascites tumour cells (●——●), LNC of A mice (○- - -○), thymus cells of A (■-·-■), AKR (▲——▲), or 129 mice (△——△). Volumes (50 μl) of a 1:4 dilution of antiserum were incubated with varying numbers of cells for 30 min at room temperature. Volumes (20 μl) of antisera were assayed in duplicate as described in the legend to Fig. 1. The residual cytotoxic activity was calculated by the formula

(% lysis by absorbed antiserum/% lysis by unabsorbed antiserum) × 100.

The C1300 tumour is maintained in several laboratories by subcutaneous passage in strain A mice. For this study, the tumour was converted to an ascites form by repeated intraperitoneal passage of tumour cells into A_{sirong} mice, referred to subsequently as A mice. Two weeks after the intraperitoneal injection of 3×10^6 C1300 tumour cells, approximately 2×10^7 ascites cells could be obtained per mouse. The ascites cells used in these experiments were between 90% and 95% viable. Of the viable cells, more than 90% were C1300 tumour cells.

Antiserum was raised in adult Wistar rats by six intraperitoneal injections of 10^7 viable ascites tumour cells, at intervals of 14 days. The rats were bled 2 weeks after the last injection. Before absorption with mouse lymphoid cells the antiserum had a cytotoxic titre of 1:300 against both C1300 tumour cells and lymph node cells of A mice. The antiserum was absorbed five times for 30 min at room temperature with equal volumes of a mixture of spleen and thymus cells obtained from A, C3H/He, BALB/c, AKR, and C57BL (C57) mice. The absorbed antiserum was not cytotoxic for LNC of A or C57 mice. When tested against C1300 tumour cells, the antiserum had a cytotoxic titre of 1:16 (Fig. 1). In indirect immunofluorescence studies, using fluoresceinated sheep anti-rat immunoglobulin antibody, 93% of the viable ascites cells incubated with a 1:4 dilution of rat anti-C1300 antiserum demonstrated bright ring fluorescence. C1300 cells incubated with normal rat serum did not fluoresce. Less than 1% of LNC, thymus cells, or spleen cells of A mice were fluorescent after incubation with either rat anti-C1300 antiserum or normal rat serum. Aliquots of a 1:4 dilution of rat anti-C1300 antiserum were absorbed with varying numbers of C1300 ascites tumour cells, LNC of A mice or thymus cells of A, AKR, or 129 mice and tested for cytotoxic activity against C1300 tumour cells. A sample of 5×10^6 C1300 cells

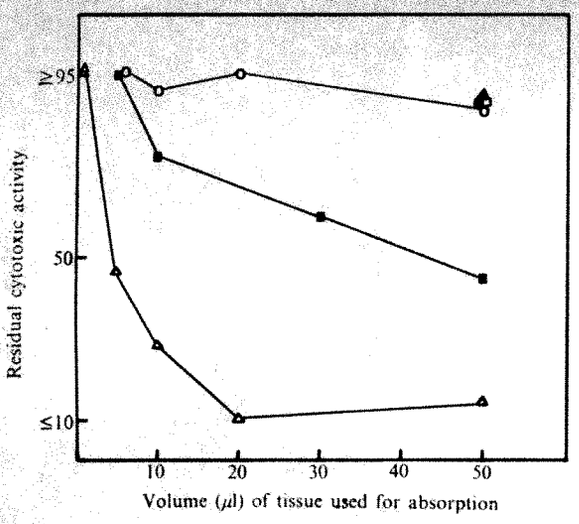

FIG. 3 Residual cytotoxic activity of rat anti-C1300 antiserum after absorption with various amounts of brain (△), kidney (■), liver (○), muscle (●), spleen (▲) and testes (□) of A mice. Volumes (50 μl) of a 1:4 dilution of antiserum were incubated with a measured volume of tissue at room temperature for 30 min. Volumes (20 μl) of absorbed antisera were assayed in duplicate as described in the legend to Fig. 1. The residual cytotoxic activity was calculated as described in the legend to Fig. 2.

removed all cytotoxic activity. No significant activity was removed by any of the other cell types (Fig. 2).

To investigate whether the antigen recognised by the rat anti-C1300 antiserum was a normal tissue antigen of A mice, aliquots of a 1:4 dilution of the antiserum were absorbed with various tissues of A mice and tested for residual cytotoxic activity against C1300 tumour cells. A putative anti-H-2^a antiserum raised in C57 mice by three intraperitoneal injections of 2 × 10^6 spleen cells of A mice was absorbed and tested in parallel. To control for dilution and possible non-specific absorption by the tissues, aliquots of the rat anti-C1300 and the C57 anti-A antisera were also absorbed with syngeneic rat tissues. The cytotoxic activity of the rat anti-C1300 antiserum was removed by brain and, to a lesser extent, by kidney of A mice. Brain tissue of A mice did not absorb appreciable amounts of antibody activity from the anti-H-2^a antiserum. Liver, lung, spleen, and testes of A mice, could remove cytotoxic activity from the anti-H-2^a antiserum, but did not remove a significant amount of cytotoxic activity from the rat anti-C1300 antiserum. Absorption with muscle from A mice did not significantly lower the cytotoxicity of either antiserum (Table 1). In further experiments, aliquots of antiserum absorbed at a 1:4 dilution with either brain, kidney, liver, muscle, or spleen were tested for residual cytotoxic activity at 1:4, 1:8, 1:16, and 1:32. Compared with Wistar rat tissues, only brain and kidney of A mice removed significant amounts of cytotoxic activity from the antiserum. To estimate the relative amounts of the antigen expressed on brain and kidney of A mice, 50 μl volumes of a 1:4 dilution of the rat anti-C1300 antiserum were absorbed with various amounts of these tissues. The results of these experiments indicated that there was at least 10 times as much of the antigen on brain as on kidney of A mice. Liver, muscle, spleen, and testes did not absorb appreciable amounts of the cytotoxic activity (Fig. 3). The antigen recognised by

TABLE 1 Residual cytotoxicity of absorbed antiserum

	Rat anti-C1300 antiserum		C57 anti-A antiserum

Testes	88	NT	58	80

Residual cytotoxic activity of rat anti-C1300 and C57 anti-A antisera absorbed with various tissues. Organs were removed from exsanguinated animals and chopped into pieces of roughly 1 mm^3. The chopped tissues were pressed through a 333 mesh nylon net and the filtered suspensions washed four to seven times with medium containing 10% FCS. Diluted antiserum (50 μl) was absorbed with an equal volume of packed tissue for 30 min at room temperature. Volumes (20 μl) of absorbed antisera were tested as described in the legend to Fig. 1. The residual cytotoxic activity was calculated as described in the legend to Fig. 2. The titre of the C57 anti-A antiserum was 1:40 against both C1300 tumour cells and LNC of A mice. A 1:10 dilution of the antiserum was used in the absorption experiments. NT, not tested.

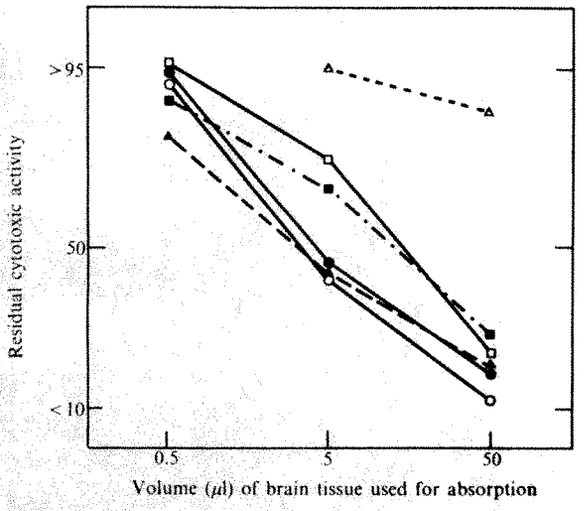

FIG. 4 Residual cytotoxic activity of rat anti-C1300 antiserum absorbed with various volumes of packed brain tissue of A (●——●), C57 (■-·-■), C3H/He (○——○), CBA (▲- - -▲), or DBA (□——□) mice or Wistar rats (△- - -△). The brain tissues were prepared as described in the legend to Table 1. Brains were removed from animals between 3 and 4 months of age. The residual cytotoxic activity was calculated as described in the legend to Fig. 2.

rat anti-C1300 antiserum was expressed in comparable amounts on the brains of A, C57, C3H/He, CBA, and DBA mice (Fig. 4).

C1300 tumour cells express several cell surface antigens present on brain as well as other tissues of certain mouse strains[10]. These antigens include H-2^a, the major histocompatability antigen of A mice; the θ-C3H alloantigen; Pc-1, the plasma cell alloantigen; GCSA, the Gross cell surface antigen; Sk-1, the skin alloantigen; and the NZB autoantigen. None of these alloantigens is expressed predominantly on nervous tissue or present on the nervous tissue of all strains of mice. The inability of LNC or thymus cells of A mice to absorb the cytotoxic activity of the rat anti-C1300 antiserum indicates that the antigen recognised by the antiserum is neither H-2^a, θ-C3H nor the NZB autoantigen. The inability of thymus cells of AKR or 129 mice to absorb the cytotoxic activity of the antiserum eliminates the possibility that the antigen is either GCSA or GIX[11], Gross virus-related antigens. The antigen detected by the rat anti-C1300 antiserum is not Pc-1 since Pc-1 is present on liver and spleen as well as brain and kidney of A mice. Nor is the antiserum directed against the serologically defined Sk-1 antigen expressed on the brain tissue of A mice since a different Sk antigen is expressed on the brain tissue of C57

mice. In addition, Sk has not been reported to be present on kidney tissue. Thus, the antigen recognised by the rat anti-C1300 antiserum is a normal tissue antigen of A mice present on brain and, to a lesser extent, on kidney, but not on liver, lung, muscle, spleen or testes and distinct from the alloantigens previously determined to be present on both C1300 tumour cells and A brain. In subsequent communications, this antigen will be referred to as mouse brain antigen-1 (MBA-1).

I thank Professor N. A. Mitchison and Dr M. C. Raff in whose laboratories these experiments were carried out. S.E.M. is supported by a US Public Health Service Grant.

Flagellar rotation and the mechanism of bacterial motility

BACTERIAL flagella are generally composed of three morphologically distinguishable regions: (*a*) the long flagellar filament which accounts for more than 95% of the flagellar protein; (*b*) the hook, which is generally 80–90 nm long and has a characteristic shape, and (*c*) the basal structure which is composed of an intricate set of disks and rods attaching the hook to the cell membrane and cell wall[1–3].

Explanations of how the flagella move[4] include the suggestion that helical waves are propagated along the filament[5,6], or that the filament behaves as a semrigid helical rotor[4,7,8]. Berg and Anderson[9] concluded that the evidence ". . . favours a model in which each filament rotates". The data presented here adds strong support to the existing evidence and provides a way to follow flagellar function that is independent of translational motility.

The methods that have been used to study motility depend on observation of the behaviour of the whole organism. This is a complex result of a series of events and is thus, at times, difficult to analyse and interpret. It would be useful to be able to follow the motion of a single flagellum or to assay for its activity in a way that does not depend on chemataxis or cell motility. To do this, a series of experiments was designed based on the observation that bacteria can be found which appear to be 'tethered' by their flagellum to a particle of debris or to the surface of the microscope slide[7]. These bacteria rotate rapidly. The rotation could reflect the motion of the tethered flagellum or it could result because the remaining untethered flagella cause the cell to move. To examine this motion in greater detail, we used 'polyhook' mutants of *E. coli*[10], which carry two mutations, one in the *hag* gene which eliminates the formation of the flagellar filament and another in the *flaE* gene which causes the loss of a function necessary to terminate the assembly of the hook structure. These cells make continuous polyhooks which can be 1–2 μm long and they are nonmotile. However, when dilute anti-polyhook antibody is added to a suspension of cells, they form clumps and begin to rotate rapidly. Several situations have been observed: the bacteria seem to be trapped or attached to the slide; the bacteria are bound to each other in pairs and counter-rotate or one rotates while the other is stationary; large groups of bacteria are cross linked and rotate or move with a jerking type of motion. Ten to twenty per cent of the bacteria in a microscope field can be found to be rotating. Figures 1 and 2 illustrate the first two situations. In Fig. 1, the cell seems to be attached to the surface of the microscope slide. It rotates 360° in a counterclockwise direction around an axis through one end of the cell body. The speed of rotation of an individual cell varies from two to nine revolutions per second. The cells can be observed to modulate their spinning in three ways: (*a*) by continuing to spin counterclockwise; (*b*) by stopping and then restarting in the same direction, or (*c*) by changing direction and spinning clockwise. The cells generally spin

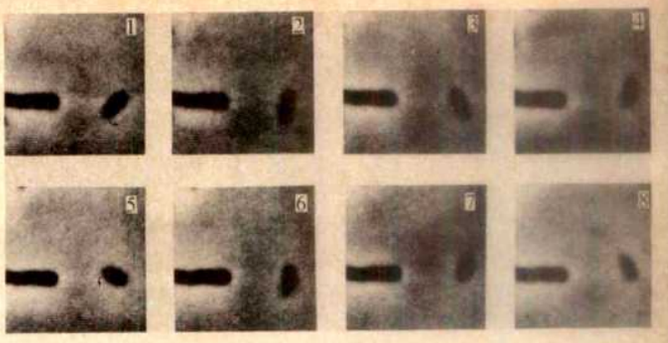

FIG. 1 The rotation of a cell bound to the microscope slide. *E. coli* strain MS1381 was grown on minimal medium with glycerol as the carbon source. Cells were put on a microscope slide and an equal volume of antipolyhook antibody diluted to 1:200 was added. After a 10 m lag, the cells began to spin. Their behaviour was recorded through a Zeiss phase contrast microscope onto video tape and then transferred to film. The pictures presented represent frames taken at intervals of 1/12 of a second. The cell at the left did not move during the sequence and it provides a reference point.

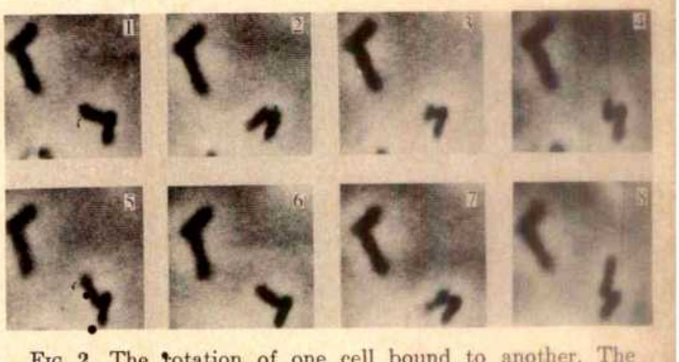

FIG. 2 The rotation of one cell bound to another. The preparation was the same as that described in the legend to Fig. 1. The cells in the upper left corner serve as reference.

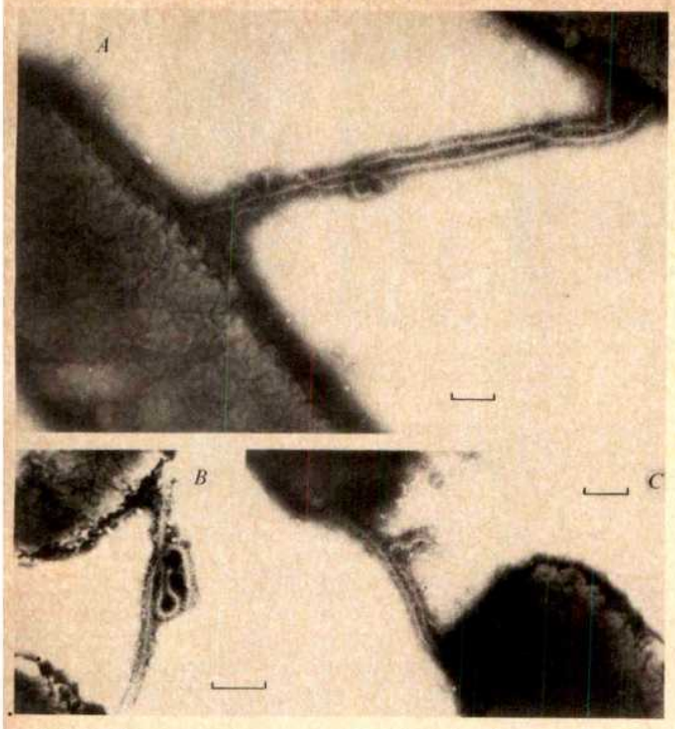

FIG. 3 Electron microscopy of cells bound together via their polyhooks. The cells were prepared as described in Fig. 1. They were placed on copper grids covered with carbon coated formover and stained with 0.5% phosphotungstic acid. The polyhook structure generally appears to be helical with a diameter of about 16 nm (ref. 10). These, however, are straightened and thickened as a result of the antibody molecules bound to them. The line in the photograph represents 0.2 nm. *A*, two cells held together by antibody bound to three polyhooks, *B* and *C*, cells held together by antibody bound to polyhooks derived from each of them.

counterclockwise and occasionally stop or reverse direction for one or two turns and then resume spinning counterclockwise. Individual cells tethered in this way have been observed to spin with intermittent short pauses for more than 30 m. Figure 2 illustrates the motion observed with a pair of tethered bacteria. Again the observations are most consistently interpreted as resulting from the complete rotation of one of the cells about a point of attachment to the other cell. The attachment appears as a narrow gap between the cells (Fig. 2, frame 4 and frame 8) which could correspond to the polyhook-antibody complex.

Thus, it is clear that the cells can rotate. However, it is possible that they rotate around the point of attachment, using the antibody as a swivel rather than rotating around the point of insertion of the basal structure into the cell body. Figure 3 shows electron micrographs of the tethered cells. It is clear that the polyhook structures are coated with antibody molecules, they bind the structures together at many points. The polyhooks have lost some of their characteristic helical appearance and are straightened, suggesting that they have some structural flexibility. The multiple attachment points along the surface of the polyhook appear to stitch them together and make it seem highly unlikely that the cells could rotate around the attachment site.

While these experiments were all done using the polyhook mutant, similar experiments were possible with bacteria that had flagellar filaments. *E. coli* strain W3110 which we used carries a mutation in the *hag* gene that results in the synthesis of straight flagellar filaments lacking the characteristic helical appearance. The cells are nonmotile. Nonetheless, indirect evidence suggests that the flagella are active[11]. To decrease the number of flagella per cell so that they would not tangle and crosslink, the bacteria were grown in minimal medium with glucose as a carbon source[12,13]. When dilute antiflagellar filament antibody was added to these cells they were tethered to the glass and to each other. They began to rotate in the same manner as the polyhook mutants. Thus, even with the straight flagellar filament the cell rotation is observed.

All these observations are concerned with the rotation of the cell, and the rotation of the filament is inferred. To observe the activity of the filaments themselves, we used small latex beads 0.7 μm in diameter (Dow), which were incubated with a 1:1,000 dilution of anti-flagellar antibody and then washed in 0.01 M Tris buffer, *p*H 7.8, and 0.1 M sodium chloride. They were added to suspensions of *E. coli* W3110 that had been grown in minimal medium with glucose. Beads were found attached 1–2 μm from the bacterium and they rotated very rapidly. In the same way, beads could be attached to flagella on wild-type bacteria and these were again observed to rotate rapidly, trailing behind motile bacteria.

All these observations, taken together, can be explained best if the hook is driven in a rotary fashion, probably by a mechanism anchored to the cell body at the base of the flagellum. This results in the rotation of the flagellar filament. Furthermore, the cell has the capacity to vary the speed and direction of rotation as well as the frequency of stopping and restarting. The ability to modulate the rotation of flagella may be the basis for the mechanism of chemotaxis.

Change in direction of flagellar rotation is the basis of the chemotactic response in *Escherichia coli*

BERG and Anderson[1] recently argued from existing evidence that bacteria swim by rotation of their helical flagella. Silverman and Simon[2] have now provided a clear demonstration of this. By means of antibodies specific for flagellar components, they tethered cells to microscope slides or to each other and observed rotation of the cell bodies. The cells were able to stop and to rotate in either direction. It seemed possible, as they proposed[2], that cessation or reversal of flagellar rotation might be involved in bacterial chemotaxis. Accordingly, we used wild-type and chemotaxis-defective mutant cells of

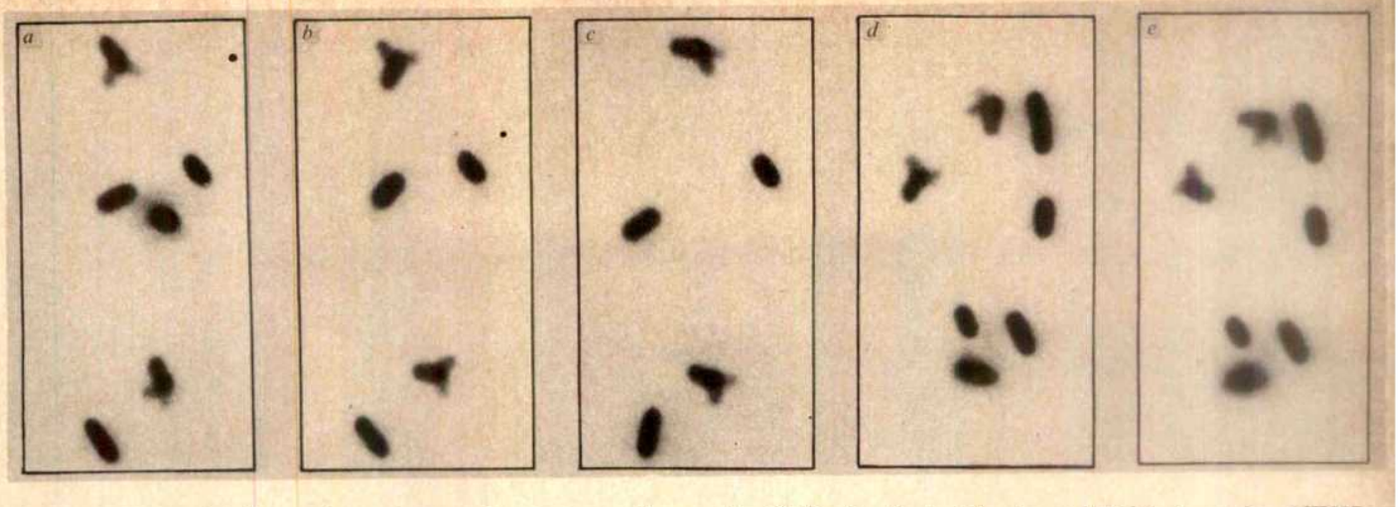

FIG. 1 Tethered cells rotating and responding to temporal chemical gradients. Rotating cells were adhered to glass slides by antibody-mediated fixation of a single flagellar filament. Bacteria were grown in glucose to reduce the number of flagella per cell[2,9,10]. (About 30% of cells had flagella with an average number of 1.5 per cell compound with 4.3 for glycerol-grown cells as counted by electron microscopy.) This was necessary for reproducible results, presumably because additional flagella could tangle and crosslink[2], or cause additional torque on the cells. Bacteria, grown in liquid glucose minimal medium[4] to logarithmic phase, were washed twice by centrifugation in chemotaxis medium (10 mM potassium phosphate, 0.1 mM potassium EDTA, *p*H 7.0), and resuspended in the same. A sample of bacterial suspension was mixed with 0.003 volumes of anti-filament antibody in chemotaxis medium (an amount just sufficient to produce rotation of cells), and then immediately placed on a glass microscope slide. After 2 min untethered cells were rinsed off with chemotaxis medium to improve the dark-field image of rotating cells. Addition of antibody eliminated the small proportion of free swimming cells; furthermore, less than 5% as many rotating cells were found in the absence of antibody as in its presence, and these readily washed away. A 5μl sample of chemotactic agent in chemotaxis medium was then added to the approximately 50 μl drop remaining over the tethered cells, using Drummond microcapillary pipettes. Photomicrographs were taken with three exposures, each of two-fold decreasing duration 1/20 s apart, generated by three slits of decreasing width in a rotating disk in the light beam. Negative prints of dark-field images are shown. Therefore, to determine directions of rotation, follow cell bodies from darkest, to intermediate, to most faint exposure. The same field of wild type (AW405) is shown with (*a*) no addition, (*b*) addition of 0.15 M L-leucine, and (*c*) subsequent addition of 0.1 mM L-serine. The same field of the tumbling mutant AW620 is shown with (*d*) no addition, and (*e*) addition of 0.1 mM L-serine. (Approximate magnification is ×2,600.)

Escherichia coli tethered to microscope slides in a manner similar to that of Silverman and Simon[2], and stimulated them by sudden increases of chemotactic agents. We found that changes in the direction of flagellar rotation indeed constitute the basis of chemotaxis: addition of attractants causes counter clockwise (CCW) rotation, whereas repellents cause clockwise (CW) rotation.

Historically bacterial chemotaxis has been identified[3] and measured[4] using an assay in which bacteria swim into a capillary tube containing attractant. More recently, chemotaxis has been studied by analysing the frequency of abrupt changes in direction of swimming (tumbles) of individual cells of *E. coli*[5,6] and *Salmonella typhimurium*[7,8] when they are presented with chemical gradients. Each tumble results in a new randomly chosen swimming direction[5] such that variation of the frequency of tumbles causes a net migration of cells during a spatial chemotactic response. In this report we conclude that tumbles are caused by CW flagellar rotation whereas smooth swimming is caused by CCW rotation.

In the absence of added attractants or repellents, rotation of tethered wild-type cells as viewed from above is biased to the CCW direction[2] (Fig. 1*a* and Table 1, strains AW607, AW405 and AW574). CCW rotation of the cell body corresponds to CCW rotation of the flagellum if viewed along the helix axis toward the point of insertion in the cell.

Changes in the direction of flagellar rotation are shown to be involved in chemotaxis by the following evidence. (1) Repellent additions (L-leucine) cause CW rotation of wild-type cells (Fig. 1*b* and Table 1). Note that mutants unable to respond to L-leucine in conventional tests for chemotaxis (AW608 and AW518) show no significant change. (2) Attractant additions (L-serine or L-aspartate) cause CCW rotation of wild type cells, and can even reverse CW rotation initiated by previous L-leucine addition (Table 1 and Fig. 1*a*, *b* and *c*). However, mutants with defective responses to L-serine or L-aspartate (AW518 and AW539 respectively)[11] show no response to a corresponding chemotactic stimulus (Table 1). These mutants respond normally to other chemicals (data not shown). (3) The generally non-chemotactic mutants (unable to respond to any known chemicals)[12,13], *cheA*593, *cheB*590, and *cheC*497, rotate only in the CCW direction, even following stimulation by L-leucine (Table 1). (4) Mutants which tumble incessantly when suspended in chemotaxis medium (for example, AW620), almost always rotate CW (Fig. 1*d* and Table 1). This tumbling mutant is capable of a subnormal but significant response to L-serine in a capillary assay (data not shown), and tethered cells reverse to predominantly CCW rotation when stimulated with L-serine (Fig. 1*e* and Table 1). (5) By adding chemotaxis medium to a drop containing tethered cells (AW405), we found that a forty-fold dilution of L-serine (from 20 μM) reversed the cells from CCW to predominantly CW rotation for 1–2 min. A similar dilution from 20 mM L-leucine immediately reversed their previous L-leucine-stimulated CW rotation. Thus decreasing temporal gradients have the opposite effect on rotation to that of increasing gradients.

The following experiments (data not shown) were performed to substantiate the above evidence. (1) Chemotactically inert agents (chemotaxis medium, 20 mM glycerol, 20 mM D-gluconate or 20 mM DL-lactate)[11,14] had no effect on the direction of rotation. (2) Other attractants (1 mM D-glucose, 20 mM glycine or 20 mM L-methionine)[11,14] also cause CCW rotation. (3) Other repellents (20 mM L-isoleucine, 20 mM L-phenylalanine or 0.4 mM potassium salicylate[14a] caused predominantly CW rotation. (4) Non-metabolisable attractants (20 mM α-aminoisobutyrate or 2 mM DL-α-methylaspartate)[11] elicited CCW rotation. Hence, availability of energy or metabolism of chemotactic agents is neither involved in chemotaxis[11,15] nor in the rotational changes we observe. (5) The effects with both attractants (even the non-metabolisable analogues) and repellents were observed to decay to the original state of rotation at times ranging from one-half to several minutes after the stimulus. Thus the effects are due to temporal stimulation and not simply

TABLE 1 Rotation of tethered wild-type and taxis-defective cells before and after chemotactic stimulation

Cells were grown and prepared for observation as described in Fig. 1, except that 'untethered' cells were not rinsed from the slide. Rinsing is recommended when increased reproducibility is required. Occasionally, a cell would appear to become stuck, or to change its centre of rotation during timing. Data from such cells were not included.

* All strains are derivatives of *E. coli* K12.

† Five or 10 μl of stimulant in chemotaxis medium were added to 20 μl drops covering tethered cells by using Drummond microcapillary pipettes.

‡ Each cell was observed for 30 s beginning immediately after stimulation. Times were determined manually with one stop clock for CW and another for CCW rotation. The infrequently observed short periods of no rotation were not included in the calculations.

§ See ref. 14a

¶ A *gal*$^+$, *su*$^-$ derivative of AW405.

to presence of the chemical. (6) Rotational responses of several strains before and after stimulation were confirmed by high speed microcinematography. (7) Tethered cells of the polyhook mutant[2] showed rotational responses to stimulation identical to wild-type cells. (8) Tethered cells of a paralysed mutant (flagellated but non-motile)[13] did not rotate even in response to attractants or repellents.

From the above results we conclude that changes in direction of flagellar rotation are the basis of both positive (toward attractants) and negative (away from repellents) chemotactic responses.

As mentioned above, chemotaxis occurs by means of variation of the tumbling frequency. Increasing attractant concentrations (whether encountered as temporal stimuli, or while swimming in spatial gradients) cause cells to tumble less frequently[5–8], while increasing repellent concentrations cause more tumbling[8]. On the other hand, decreasing concentrations cause the opposite effect (more tumbling for attractants and less tumbling for repellents)[7,8]. What, then, is the relationship between direction of flagellar rotation and tumbles?

The generally non-chemotactic mutants swim smoothly with virtually no tumbles[10] and, when tethered, never rotate in the CW direction (Table 1). On the other hand, mutants which tumble continually rotate their filaments in the CW direction most of the time (Table 1). Furthermore, these mutants swim smoothly and rotate their filaments predominantly in the CCW direction only when stimulated by attractants. From these observations, as well as the effects of attractants and repellents on rotation of wild-type cells (Fig. 1*a*, *b* and *c*, and Table 1), we conclude that tumbling occurs as a result of CW rotation of flagella.

Peritrichously flagellated bacteria swim by coordination of several helical filaments in a bundle behind the cell[16]. Bacteria with predominantly smooth swimming (wild-type, generally non-chemotactic mutants, and responsive strains when attractant was added) all rotate their filaments predominantly in the CCW direction. Conversely, bacteria induced to tumble rotate their filaments CW. We therefore conclude that to obtain the thrust required for smooth swimming from CCW rotating filaments in a bundle, the helical sense of the filaments of *E. coli* must be left-handed. It is significant that the helix of filaments of *Proteus vulgaris*, another enteric Gram negative peritrichously flagellated bacterium, is also left-handed[17,18].

Although it is possible that cessation of rotation or differential rates of CCW rotation of filaments could cause a tumble, we believe that CW rotation is the most likely, cause, because tethered cells of tumbling mutants rarely stop rotating and seldom rotate CCW; whereas, when not tethered, they tumble very frequently. The same can also be said for cells responding to repellents. Thus cessation of rotation does not correlate with tumbling. Although we have no evidence against involvement of differential rates of flagellar rotation in tumbling, it is not necessary to invoke them in the mechanism of chemotaxis. Clockwise rotation of one or more left-handed helical filaments can lead to tangling or, more probably, dissociation of flagellar bundles, and thereby generate tumbles.

Several interesting questions arise now that it is known that flagella can rotate in either direction[2] and that this ability is basic to chemotactic responses. As proposed by Berg and Anderson[1], the morphology of the flagellar basal complex and its association with the cell envelope[19,20] is suggestive of a cylindrically symmetrical rotary 'motor'. Are there separate motors for CCW and CW rotation, or does a single motor reverse? Do the motors rotate by step-wise molecular interactions, or as 'turbines' driven by ion fluxes? How do chemotactic stimuli, acting through chemoreceptors[15], control the direction of rotation? Do chemoreceptors communicate only with a nearby flagellum, or simultaneously with all flagella?

Dynamic properties of bacterial flagellar motors

TETHERED bacteria[1] rotate at the angular velocity at which the torque generated by the flagellar motor[2] is balanced by the torque due to the viscous drag. In general, $M = b\eta\Omega$, where M is the torque, η is the viscosity, Ω is the angular velocity, and b is a coefficient which depends on the size and the shape of the cell, the position of the axis of rotation, and the distance between the cell and the wall. For a sphere of radius a (not too close to the wall) $M = 8\pi\eta a^3\Omega$ (ref. 3). Viscous forces are so large in comparison with inertial forces[4] that Ω will change with M virtually instantaneously; any discontinuities in the one will be evident in the other. Consider a cell of radius a and uniform density ρ rotating at an angular velocity Ω_0; if its motor is suddenly disengaged, Ω will decay exponentially to 0 with a time constant $\rho a^2/15\eta$, and the cell will stop in $\Omega_0\rho a^2/15\eta$ radians. For *Escherichia coli* this is less than a millionth of a revolution. The cell also is subject to rotational diffusion, but this will be evident only if the coupling between the flagellum and the body of the cell is fluid. The root-mean-square deviation in the angular position is $(2Dt)^{1/2}$, where D is the rotational diffusion constant and t is the time. For a cell which can rotate freely, $D = kT/b\eta$, where k is Boltzmann's constant and T is the absolute temperature.

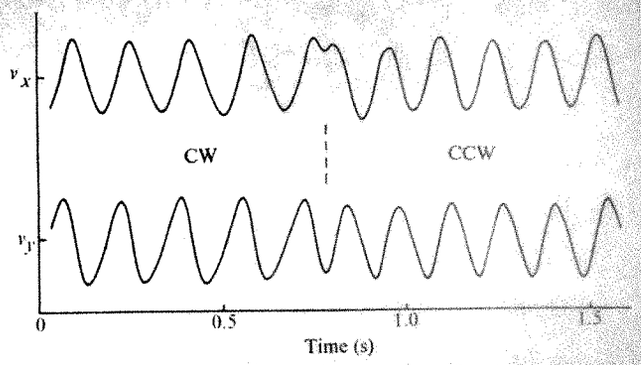

FIG. 1 The rotation of a polyhook mutant bound to the top window of the tracking chamber. The cell rotated clockwise (CW) at 6.2 r.p.s. and then counterclockwise (CCW) at 7.2 r.p.s. (The x velocity lags the y velocity for CW rotation but leads it for CCW rotation; the phase shift is 90°.) *E. coli* strain MS1381 was grown on minimal medium containing glycerol as described by Silverman and Simon[6], washed twice with a solution containing 10^{-2} M potassium phosphate (pH 7.0) and 10^{-4} M ethylenediamine tetraacetate, and suspended in a similar medium containing 0.067 M sodium chloride (10^8 cells ml^{-1}). Antipolyhook antibody was added to a dilution of 1:20,000, and the window was immersed in this mixture. It was removed 20 min later and inverted onto the top of a tracking chamber (filled with the suspension medium). The cells were tracked at 32°C. The microscope readout voltages (ref. 5, Figs 1 and 5) were amplified, differentiated, and displayed on a strip-chart recorder. The frequency response of this system was checked with sine waves of amplitude 0.05 and frequency 20 times that of the signals which generated the recording shown in the figure; the test signals were readily detectable. Note that the signals generated by the rotation of the cell are completely smooth.

The rotation of *E. coli* can be monitored with the tracking microscope[5], which follows the point on the surface of the cell closest to the centre of the laboratory reference frame. If the cell rotates counterclockwise ($\Omega > 0$), the transducer traces out a counterclockwise path. If the cell is seen from the side and is tethered near one end, the x and y velocities of the tracker vary with time roughly as $\Omega\sin\Omega t$ and $-\Omega\cos\Omega t$ (Figs 1 and 2). The exact shape of the waveform depends on the size and the shape of the cell and on the position of the rotation axis.

The motion can be remarkably smooth. If the motor makes one revolution in n discrete steps, I conclude from data of the kind shown in Fig. 1 (for cells rotating as slowly as 4 r.p.s.) that $n \gtrsim 25$. This probably rules out the mechanism envisaged earlier[2], in which a cycle is executed when each of three (or more) cross bridges takes nine steps. This mechanism could explain the data only if the motions of the different cross bridges were highly synchronised. If the response time of the tracking and recording system is τ, then the root-mean-square deviation in Ω due to rotational diffusion should be of order $(2D/\tau)^{1/2}$. Under the conditions of the experiment ($\tau \simeq 10^{-2}$ s), the value of the deviation expected for a freely rotating object the size of *E. coli* is about 6 s^{-1}. The data are much smoother than this (Fig. 1), so the coupling between the flagellum and the body of the cell is not fluid.

Changes in the direction of rotation[1] occur smoothly, yet abruptly (Figs 1 and 2), and they occur at different points in the cycle (Fig. 2 and data obtained with the polyhook mutant, not shown). The data at hand are consistent with a model in which the reversals occur at random[9]. The angular velocities for clockwise and counterclockwise rotation are generally different (Figs 1 and 2), but this does not necessarily mean that the dirve is asymmetric. When the motor reverses, the torque applied to the hook and the filament changes

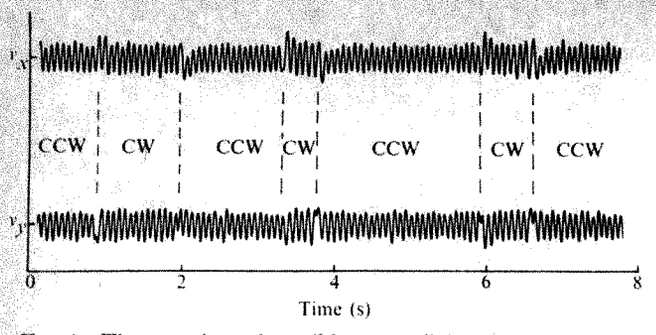

FIG. 2 The rotation of a wild type cell bound to the top window of the tracking chamber. In the interval shown the cell changed direction six times; it ran 71 cycles CCW at 13.2 ± 0.2 r.p.s. and 28 cycles CW at 12.4 ± 0.8 r.p.s. The reversals occurred at different points in the cycle. The cell was followed for a total of 6 min; the interval shown is typical of the entire record, except that the cell stopped occasionally for about 0.2 s and then started again in the same direction. *E. coli* strain AW405 (ref. 7) was grown, washed, and linked to the window by the methods of Larsen *et al.*[8] Other conditions were as described in Fig. 1.

sign; if either one changes its shape, the orientation of the cell (and thus the load) may be different. Note that the amplitudes of the signals (Fig. 1 or Fig. 2) are larger when the frquencies are lower.

Cells which rotate with larger radii of gyration tend to rotate more slowly, which implies that the motors slow down with increasing load. This was confirmed quantitatively in experiments with the polyhook mutant in which Ω was measured as a function of η (Table 1). When the motors run more slowly, they deliver somewhat more torque but less power. Since the torque is approximately constant, a cell tethered by an inert structure, such as a pilus (the point of attachment assumed fluid), and driven by a free helical filament (rotating rapidly on the opposite side of the cell) should rotate at about the same rate as a cell tethered by the flagellum itself (the point of attachment assumed rigid). I have seen this with wild type cells: in the absence of antibody, as many as 90% spin the wrong way (at the usual rates but predominantly clockwise on the slide, counterclockwise under the coverslip). As Silverman and Simon[1] note in the accompanying report, a distinction between rotation and other means of propulsion cannot be made with tethered cells unless they are non-motile when free.

Cells rotate perfectly well at high osmotic pressures, even when visibly plasmolysed (experiments with the polyhook mutant in 0.25 and 0.50 M sucrose). When the osmotic strength is increased, some cells slow down, but most continue to rotate rapidly (Ω in the range expected from changes in η). At higher osmotic strengths (0.75 M sucrose) most cells stop. These effects are reversible. The results are consistent with those obtained by Vaituzis and Doetsch[10,11], who found that flagellated spheroplasts swim in a medium isotonic to the cytoplasm provided that they retain remnants of the cell wall. Severe plasmolysis may cause reversible disruption of flagellar basal structures[12].

A model for a flagellar motor is presented in Fig. 3. The motor operates with two rings (the M and S rings), since only two have been found in Gram positive bacteria[13]. Four have been identified in Gram negative bacteria[13], but the outer pair probably serve as part of a bushing required for passage of the rod through the multilayered wall. The M ring has been shown to be associated with the cytoplasmic membrane in both Gram positive and Gram negative cells[14], but specific attachments of the S ring to known cell envelope structures have not been found. The motor must be attached to the wall somewhere, or else the torque which it can generate cannot be applied. If the rings are pulled away from the wall[12] or if the wall is dissolved away[11], the rings may continue to rotate relative to one another, but they will not drive the cell.

Lubrication does not seem to be a problem, the reason being that everything is very small. I have computed the torque due to the viscous shear in the space between the rod and the wall and in the space between the M and the S rings[3] and approximated the torque due to the rotation of the M ring in the membrane by half the torque on a sphere of similar radius. If the passage through the wall is 20 nm long, the gap between the M and the S rings is 0.5 nm thick, and the viscosity is 1 P (see Fig. 3 for the other dimensions), the internal drag is only 3×10^{-4} times as large as the drag on the body of the cell.

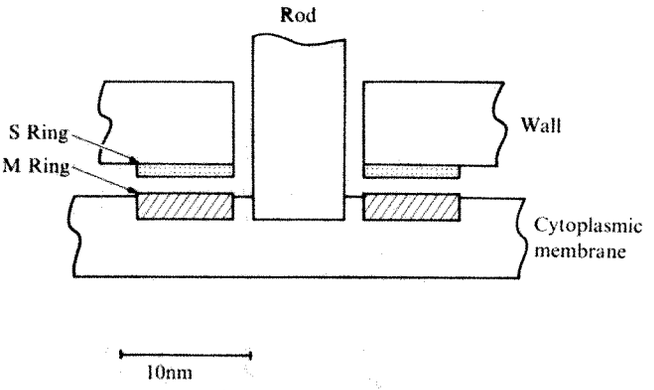

FIG. 3 A schematic representation of a flagellar motor. The rod is connected to a filament by a proximal hook (not shown). The torque is generated between the M ring and the S ring. The M ring, which is mounted rigidly on the rod (connections not shown), rotates freely in the cytoplasmic membrane. The S ring is mounted on the wall. The radius of the rod is 3.5 nm and the inner and outer radii of the rings are 5 nm and 11.2 nm, respectively[13]. (The wall thickness and the space between the M and S rings are not to scale.)

TABLE 1 Changes in angular velocity, torque and power dissipation resulting from changes in viscosity

Relative change in viscosity	2.42*	2.31†
Relative change in angular velocity	0.50 ± 0.08	0.51 ± 0.09
Relative change in external torque	1.21 ± 0.19	1.18 ± 0.21
Relative change in power dissipation	0.61 ± 0.22	0.60 ± 0.19

Cells were tethered to microscope coverslips by the method described in the legend of Fig. 1 and examined manually at 32°C. Cells rotating at uniform rates (0.3–3 r.p.s.) were clocked for about 1 min, the medium was replaced with one containing more (or less) methylcellulose (Dow Methocel 90 HG), and the measurements were repeated. Since the cells had different shapes and sizes and were tethered in different ways, the relative changes in Ω (and hence in the torque $b\eta\Omega$ and in the power dissipation $b\eta\Omega^2$) were computed for each cell separately. The data were obtained from twenty-one paired measurements on ten cells from four cultures. The standard deviations shown in the table were computed by weighting each pair of measurements equally. The viscosities were determined at 32°C with a Cannon-Ubbelohde viscometer.

* 0.776 to 1.88 cP.

† 1.88 to 4.35 cP.

The motor must bear both axial and radial loads, since the rod in a peritrichously flagellated bacterium rarely lies along the direction of motion. The forces are of order $6\pi\eta av$, where a is the radius of the cell (approximated as a sphere) and v is its speed; that is, of order 10^{-8} dynes. When an intact cell swims in a dilute solution, the axial load is more than balanced by osmotic pressure, which forces the M and S rings out against the wall (a force of order 10^{-5} dynes); when a spheroplast swims in a medium isotonic to its cytoplasm, the axial load is not balanced in this manner. As noted above, the coupling between the flagellum and the body of the cell

is not fluid, so the axial and the radial loads can be borne at the point of contact (between the M and the S rings).

How is the torque generated? Larsen *et al.*[15] have found that an intermediate in oxidative phosphorylation (but not ATP) is required for motility in *E. coli*. This suggests a mechanism in which the movement of one molecule down an electrochemical gradient (through the membrane) causes another molecule to exert a force on the S ring in a direction parallel to its face but normal to its radius. A force in the opposite direction could result from a change in the coupling between these molecules or from the action of an independent set. Since the power dissipation for an *E. coli* spinning 10 r.p.s. is of order 10^{-9} erg s^{-1} and the energy which can be gained from the transit of one molecule through the membrane is of order 10^{-13} erg, 10^3 such events could drive the cell through one cycle. The individual steps would be too small to be seen in the present experiments.

I thank Melvin Simon and Steve Larsen for mutants, antibodies and communication of results before publication, Pat Tedesco for technical assistance, and Edward Purcell for comments on the manuscript. This work was supported by a grant from the US National Science Foundation.

Presence of HCN in *Chlorella vulgaris* and its possible role in controlling the reduction of nitrate

NITRATE reductase of *Chlorella vulgaris* is present in crude extracts mainly in an inactive form[1–3] which may be converted to an active form by the addition of an artificial oxidant such as ferricyanide[4]. In crude extracts from which low-molecular weight substances have been removed by gel filtration, added NADH (or NADPH) causes a rapid conversion of the active form of nitrate reductase to the inactive form[5]. Losada and coworkers have also observed an inactivation of the nitrate reductase from *Chlorella fusca*[6] and *Chlamydomonas reinhardi*[7] by added NADH. A low-molecular weight fraction separated from crude extracts of *Chlorella vulgaris* also causes an inactivation of nitrate reductase when added back to the extract which had been treated with ferricyanide and passed through a Sephadex column to remove excess reagent[5]. In all cases the enzyme can be reactivated by the addition of the oxidant, ferricyanide[4–8]. On purification of the enzyme, Solomonson[9] found that two substances must be present simultaneously to cause the reversible inactivation: (1) a reducing substance, preferably NADH, and (2) a substance that behaves like HCN. The molar concentration of HCN needed to effect a rapid and reversible inactivation of the enzyme was of about the same magnitude as the enzyme concentration. Thus, activated, suitably purified nitrate reductase with added excess NADH, provides an exceedingly sensitive, though non-specific test for HCN, as shown in Fig. 1.

Although this bioassay could not be applied directly to extracts, it could easily be used to show that distillates prepared from *Chlorella* cells, or from extracts of *Chlorella* cells, contained something which behaved like HCN. The concentration of the unknown substance could be increased by redistillation until it came within the sensitivity range of specific chemical tests, which showed that the substance was, indeed, HCN. After many preliminary experiments, conditions were found for obtaining sufficiently high HCN concentrations in the first distillate to come within the range of a chemical test as well as of the bioassay. The results of a series of such experiments, given in Table 1, show that the amount of HCN which could be obtained from freshly collected *Chlorella* cells was somewhat greater than the amount of nitrate reductase present in the cells. Thus, the quantity of HCN found can account for the fact

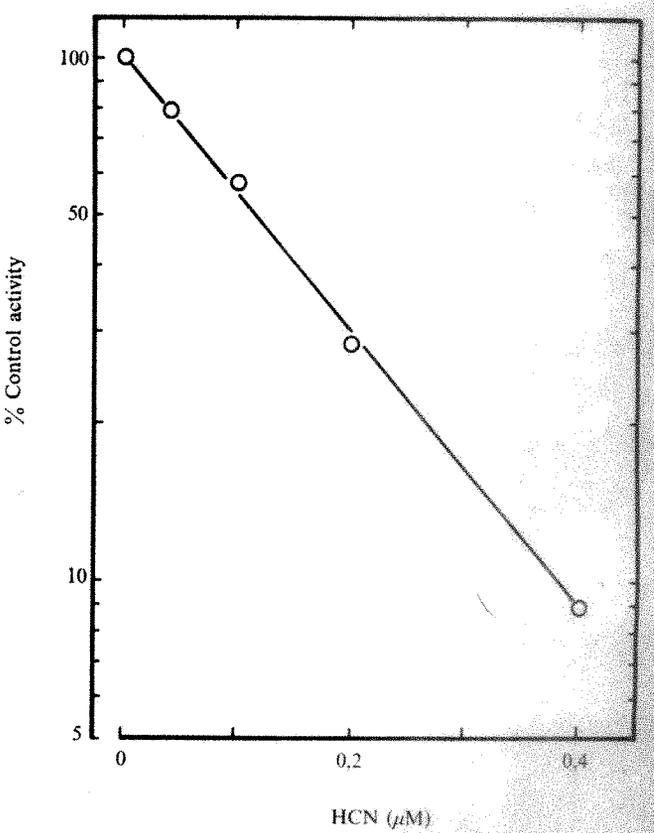

FIG. 1 A calibration curve for the bioassay for HCN. The percentage inactivation of nitrate reductase is plotted on a log scale against the initial HCN concentration. Incubation mixtures containing 0.05 M Na,K phosphate buffer (*p*H 7.6), 0.2 mM NADH, and the indicated concentrations of HCN were brought to 20° C. The inactivation was initiated by addition of activated enzyme to a concentration of 0.86 units ml^{-1}. After 6 min, aliquots were added to the enzyme assay mixture and activity was assayed as previously described[1,9]. A control inactivation mixture without cyanide, gave 95% of the initial activity. This was taken as 100% for calculation of the percentage inactivation. It is essential that all HCN be removed from the enzyme preparation, so that NADH alone gives a negligible inactivation. The preparation of the enzyme is described elsewhere[9]. The sensitivity of this bioassay can be increased by decreasing the concentration of enzyme.

TABLE 1 HCN from *Chlorella* cells

Cells (ml)	HCN (nmol per ml cells) Bioassay	Chemical assay
23.7	1.22	1.38
21.3	1.27	1.62
28.0	1.26	1.39
27.5	2.05	1.75
(Mean)	1.45	1.53

Chlorella vulgaris was grown under the conditions used for the preparation of nitrate reductase[1,5,9,23]. HCN was separated by simple distillation. In the first experiment, 23.7 ml freshly collected, packed cells were washed with 500 ml redistilled water and suspended in a distillation flask in enough water to give 0.5 ml cells per ml suspension. An equal volume of 1 N H_2SO_4 was added, and distillation was begun immediately. The condenser was well cooled, and the receiving flask was held deep in an ice bath. Several fractions of distillate were collected, until no further active material was obtained. Over 90% of the total yield of HCN was obtained in the first 17 ml of distillate. Other experiments were done with minor variations. Control experiments with known HCN showed that there was negligible loss of HCN under these conditions. Another control experiment with tracer $H^{14}CN$ showed that the ^{14}C distributed itself with the chemical assay and the bioassay. Addition of alkali to the receiving flask was unnecessary and was avoided because other substances present in the distillate reacted with the HCN at alkaline pH.

The cells used for these experiments generally gave about 1.4 units of activated enzyme per ml of sonicated extract, corresponding to about 200 μl of cells. This is a yield of 7.0 units per ml cells. From the turnover number[2], we estimate that one unit of enzyme is about 0.09 nmol, which gives 0.63 nmol enzyme per ml cells, compared with 1.2 to 2.0 nmol HCN. The estimate of the amount of enzyme present is not very accurate, since we have no reliable measure of the losses sustained during the extraction procedure.

The chemical assay was carried out according to Guilbault and Kramer[11], without addition of isonitrosobenzoylacetone. Since cyanide acts catalytically in this test, the rate of colour formation was measured at 23° C. HCN (0.1 nmol) added to the test system gave $\Delta A_{560nm} = 0.0365$ in 5 min (d = 1 cm).

that the nitrate reductase present is largely in the inactive form.

Our current procedure for purifying nitrate reductase began with a protamine sulphate fractionation. This was carried out on a small scale, to show that the protamine sulphate precipitate, containing the enzyme largely in inactive form, yielded an amount of HCN which was approximately equivalent to the amount of inactive enzyme present. Thus, 32.5 ml extract (frozen, thawed, and cleared by centrifugation), which is approximately equivalent to 6.5 ml of cells, contained 46.3 units of inactive nitrate reductase (measured after activation of a separate aliquot by ferricyanide) and 1.8 units active nitrate reductase. To this extract, 1 ml of 2% protamine sulphate (*p*H 7.0) was added, and the precipitate obtained was removed by centrifugation. Another 1 ml, and then 0.5 ml of protamine sulphate were added, the precipitate each time being removed by centrifugation. From the supernatant, essentially all of the enzyme was precipitated by further addition of 2 ml 2% protamine sulphate. This precipitate was washed twice with 0.02 M Tris buffer (*p*H 8.1), suspended in 4 ml of 0.1 M phosphate (*p*H 7.2) containing 0.1 mM dithioerythritol and 0.1 mM EDTA, and brought to 10 ml with redistilled water in a 100 ml distillation flask. An equal volume of 1 N H_2SO_4 was added, and distillation was carried out as described in the legend for Table 1. Special care was required because of foaming.

The first fraction of 1.0 ml and a second fraction of 0.9 ml distillate were collected. The bioassay gave 2.86 and 0.45 nmol HCN in the first and second distillates, respectively; the chemical assay gave 2.3 and about 0.36 nmol. The total of 3.3 nmol by bioassay compared with 2.7 nmol by chemical assay. The 46 units of inactive enzyme originally present are equivalent to about 4.2 nmol enzyme, some of which must have been lost or activated during the extensive manipulation. The value of 4 thus compares quite well with the value of 3 nmol HCN recovered by distillation. In a control experiment, an equivalent amount of protamine sulphate gave no detectable HCN.

In another experiment, the final supernatant from the protamine sulphate precipitation was distilled after acidification. Here, the HCN recovered amounted to 3.7 nmol HCN per ml *Chlorella* used to make the extract. Adding the 0.6 nmol HCN removed with the inactive enzyme, this gives a total of 4.3 nmol HCN per ml cells, recovered from the extracts of *Chlorella*, compared with about 1.5 nmol per ml as the average recovered from the intact cells (Table 1). This is presented as evidence that cyanide formation occurs in the extract. In these experiments, distillates were examined by the chemical method of Epstein[10] as well as by the bioassay and by the chemical method of Guilbault and Kramer[11]. All methods gave comparable results. By the use of similar procedures, HCN could also be obtained from spinach leaves and from the blue-green alga, *Plectonema boryanum* (Gewitz and Völker, unpublished). These and further experiments will be described in detail elsewhere.

It has long been a puzzle that cyanide-utilising enzyme systems are present in cells not known to make cyanide[12–14]. Thus, Conn and his associates found in 1963[15], that added $H^{14}CN$ is converted to the β-carboxamide group of asparagine by seedlings of some so-called non-cyanogenic plants and also of some cyanogenic plants. Tschiersch[14] made similar independent observations. Fowden and Bell[16] showed that *Chlorella pyrenoidosa* converted $H^{14}CN$ to β-cyanoalanine, and thence to asparagine or to the peptide γ-glutamyl-β-cyanoalanine. The literature on HCN metabolism has been reviewed by Blumenthal *et al.*[17], who noted particularly that enzymes for the metabolic conversions of HCN are widely distributed in bacteria, fungi, algae and higher plants. Most recently, Taylorson and Hendricks[18] have described a stimulatory effect of HCN on seed germination, and ascribed it to the specific synthesis of asparagine, which may be rate limiting in protein synthesis.

We propose that HCN may play an important part in a delicately balanced system which controls the activity of nitrate reductase. The nature of the chemical interaction between cyanide and nitrate reductase has not been firmly established (see ref. 9 for discussion). The fact that cyanide inhibits the enzyme has long been known[19]. Relimpio *et al.*[20] and Solomonson and Vennesland[2] observed that the inhibition by cyanide was enhanced by NADH. This cyanide inhibition was slowly reversed by nitrate[2] and rapidly reversed by added ferricyanide[5]. The reversal of cyanide inhibition by nitrate had at least a superficial similarity to the activation of nitrate reductase in fresh extracts of *Chlorella vulgaris*[2]. Maranville[21] reported an increase in nitrate reductase activity in extracts from sorghum when nickel salts were added to the extraction buffer. He postulated that the nickel acts by binding cyanide released by the hydrolysis of the cyanogenic glycoside, dhurrin. We also noted a similar increase in activity when $NiSO_4$ was added to fresh extracts of *Chlorella vulgaris*[2] but the stimulation of activity by nickel was small by comparison with activation achieved by other methods.

We note that when a plant is called non-cyanogenic, this only means that the amount of HCN present is less than the amount which can be detected by the test used, or that no cyanogenic glycosides have been found in the material[14,22]. Our experiments show that *Chlorella vulgaris*, previously considered non-cyanogenic, actually contains HCN in bound form, some of it complexed to an inactive form of the enzyme, nitrate reductase. Extracts of these cells contain considerably more HCN, which must be formed from an as yet unidentified precursor.

We thank E. E. Conn for a helpful stimulating corre-

spondence. We also thank K. Jetschmann for help with the preliminary experiments, W. Völker for help with distillations and chemical determinations, and Renate Borchers for help in preparing enzyme for analysis and bioassay.

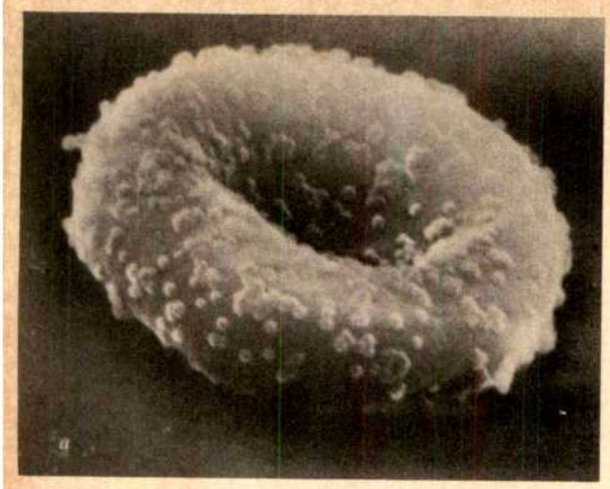
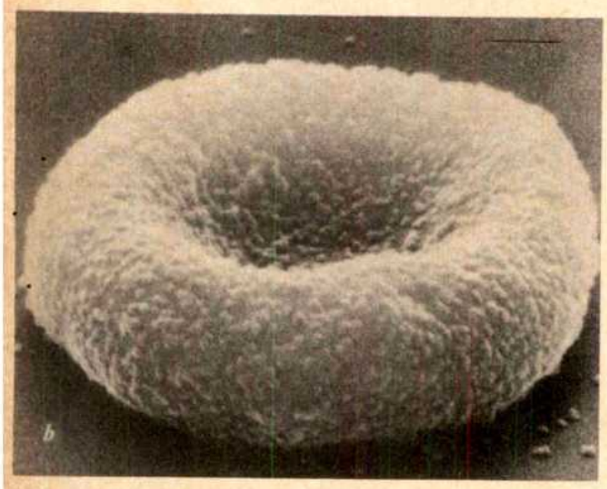
Latex spheres as markers for studies of cell surface receptors by scanning electron microscopy

THE distribution of antigens and carbohydrate residues on the surfaces of cells, notably erythrocytes and lymphocytes, can be determined by binding antibodies or lectins to such macromolecules as ferritin[1,2], haemocyanin[3,4] or peroxidase[2,5], which serve as markers for transmission electron microscopy. Improved techniques in high resolution scanning electron microscopy (SEM), however, make it possible to determine the topographical distribution of molecular receptors on the surfaces of cells and tissues by similar histochemical techniques involving markers resolvable by SEM. LoBuglio *et al.*[6] used commercial polystyrene latex particles, 2,300 Å in diameter, as immunological markers for SEM work. But applications of this reagent are limited because the hydrophobic surface of the particles makes them stick non-specifically to many surfaces and molecules.

We have developed a more useful technique, and report here: (1) the design and synthesis of latex spheres equal to or less than 1,300 Å in diameter; (2) the covalent bonding of antibodies and other molecules to these spheres, and (3) the application of antibody-tagged particles as specific cell surface markers for SEM.



The rationale for the design of polymeric latex is based on the need for small, stable particles which are biocompatible—that is, they do not interact non-specifically with cells or other biological components—and contain functional groups to which specific proteins and other biochemical molecules can be bonded covalently. A crosslinked copolymer of hydroxyethylmethacrylate (HEMA), methacrylic acid and methylmethacrylate has these characteristics: poly HEMA has blood compatible properties and is used in the manufacture of contact lenses[7]. The hydroxyl groups can be activated by cyanogen bromide[8,9] for covalent bonding of proteins to the polymeric latex. Methacrylic acid residues which impart a negative charge onto the particles prevent non-specific binding to cell surfaces and provide carboxyl groups to which various biochemical molecules can be bonded by the carbodiimide method[10]. Cross linking of the polymeric matrix is essential to maintain the stability and size of the particles in both aqueous solutions and organic solvents commonly used in the fixation and dehydration of biological specimens for electron microscopy.



Latex spheres were synthesised by aqueous emulsion copolymerisation of methylmethacrylate (MMA), HEMA and methacrylic acid (MAA) in the presence of the emulsifier sodium dodecylsulphate, the free radical initiator ammonium persulphate, and the cross linking agent trimethylol propane trimethacrylate. Polymerisation was carried out in closed tumbling containers, under argon at 98° ± 2° C, for 6 h. The chemical composition of the latex was: MMA, 57%; HEMA, 30%; MAA, 10%, and crosslinker, 3%. By varying the polymerisation conditions the diameter of the spheres could be changed from 600 to 1,300 Å. The emulsifier and other impurities were removed by passage over a mixed bed ion exchange column.

Proteins and other molecules containing amino groups were bonded covalently to the latex spheres by either the cyanogen bromide[8] or carbodiimide methods[10]. For use as visual markers in fluorescent microscopy or as reagents in quantitative studies, latex spheres (20–50 mg ml^{-1}) activated with cyanogen bromide (50 mg ml^{-1}) were tagged with the fluorescent dye, dansyl-ε-lysine, or ^{3}H-lysine (1 mM). Antibodies (0.2–1 mg ml^{-1}) were covalently bonded to latex spheres previously derivatised with ε-amino caproic acid using the coupling reagent, 1-ethyl-3-(3-dimethyl aminopropyl) carbodiimide (2 mg ml^{-1}) or spheres derivatised with diaminoheptane using glutaraldehyde (1.25%). Further details of the synthesis and coupling procedures will be described elsewhere.

The application of these immunochemical reagents as visual markers of cell surface components for light and electron microscopy was tested using the indirect or 'sandwich' technique[5]. Purified goat antibodies directed against rabbit γ-globulin (goat anti-rabbit) were coupled to the latex spheres. Unbound antibodies were removed by repeated centrifugation (35,000*g*, 30 min) and redispersion in phosphate-buffered saline (PBS). The immunochemical activity of the latex bound goat anti-rabbit antibody was verified by the agglutination of the latex in the presence of rabbit IgG.

Washed bovine red blood cells (RBC) sensitised with rabbit antiserum against bovine red blood cells (non-specific rabbit antiserum was used in the control) were incubated with goat anti-rabbit–latex conjugates (1–20 mg ml^{-1}) for 20 min at 20° C. After removal of the excess reagent by repeated centrifugation of the cells at 400*g*, the RBC were fixed in 1.25% glutaraldehyde and prepared for examination

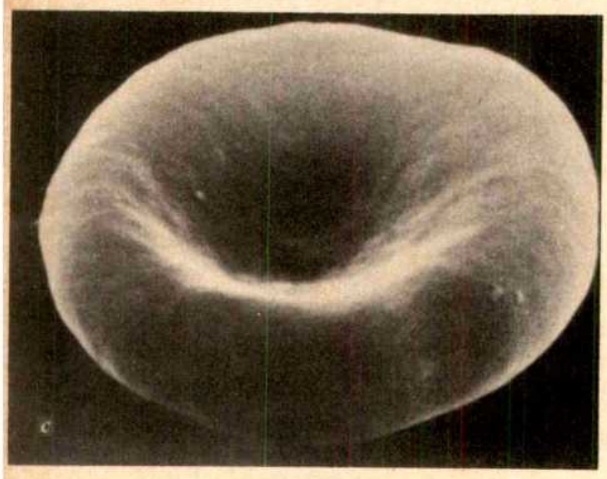


FIG. 1 Scanning electron micrograph of bovine RBC. *a*, Red blood cell labelled with rabbit anti-bovine erythrocyte antiserum followed by goat anti-rabbit antibodies covalently bonded to latex particles 1,300 Å in diameter. Only partial labelling of the cell is observed because of the low concentration of latex conjugate used. *b*, Red blood cell labelled as in (*a*) but with a higher concentration of latex particles 800 Å in diameter. (Horizontal bar represents 1 μm.) *c*, Control experiment. Red blood cell treated with non-specific rabbit antibodies followed by goat anti-rabbit antibodies conjugated to latex particles 800 Å in diameter. *d*, Mouse spleen lymphocyte labelled with rabbit anti-mouse lymphocyte serum followed by goat anti-rabbit antibodies conjugated to 800 Å latex particles. Sodium azide (5 mM) was present during labelling to prevent cap formation.

by SEM[11]. A scanning electron micrograph of a bovine red blood cell specifically labelled with a low concentration of immunolatex particles of average diameter 1,300 Å is shown in Fig. 1*a*. A red blood cell labelled with immunolatex particles of average diameter 800 Å is shown in Fig. 1*b*. The absence of significant non-specific binding of these immunochemical reagents is illustrated in the control experiment (Fig. 1*c*). A mouse spleen lymphocyte settled onto a glass cover slip and labelled first with rabbit anti-mouse lymphocyte serum and then with goat anti-rabbit–latex conjugate (20 mg ml^{-1}) is shown in Fig. 1*d*. The latex spheres coat the surface of the cell and line the microvilli.

These reagents have several advantages for studies in the mapping of specific cell surface components. They can be easily prepared and coupled to proteins and other molecules by standard chemical procedures, they are stable indefinitely, and do not bind non-specifically to cell surfaces. They can be synthesised in various size ranges and chemical compositions to suit particular requirements. For example, smaller spheres in the size range 200–300 Å in diameter can serve as molecular markers (1) in replica and shadowing techniques for high resolution transmission electron microscopy, and (2) in double labelling experiments in conjunction with larger latex particles or with such biological markers as haemocyanin distinguishable by its cylindrical shape[3]. For use with fluorescent microscopy and for quantitative studies, these reagents have the advantage that by binding fluorescent dyes and radioactive molecules to the latex instead of the antibody, a high degree of tagging can be attained without adversely affecting the antibody activity for studies requiring high sensitivity. These particles when tagged with metals or other suitable elements have application in electron beam microprobe analysis and related X-ray techniques.

The application of these multipurpose reagents in studies of antigens on the surface of more complex cell and tissue specimens is being investigated. Latex particles bound to certain hormones, lectins or toxins should prove valuable in the detection and localisation of various specific receptors on cell surfaces.

We thank S. Rosenberg for rabbit anti-bovine erythrocyte serum. This work was supported by grants from the President's Fund of the California Institute of Technology and from the National Institutes of Health. R. S. M. was supported on an American Cancer Society postdoctoral fellowship.

Calcium uptake by sarcoplasmic reticulum of muscle from vitamin D-deficient rabbits

RECENT rapid advances in understanding the metabolism and action of vitamin D have confirmed its primary effect on intestinal calcium transport and continue to elucidate its action on bone and kidney[1,2]. Biochemical research has, however, largely neglected the well-known clinical observation of proximal muscle weakness in most vitamin D-deficient states[3]. Those studies which have been done provide only indirect evidence of a link between vitamin D and muscle. Thus, autoradiography after pharmacological doses of radioactive vitamin D has shown its localisation under the sarcolemma[4], and when more physiological doses are given to rachitic animals, vitamin D and its metabolites may be found in significant amounts in muscle[5]. Skeletal muscle also contains a protein similar to the binding protein of kidney (but not of plasma) that binds 25-hydroxycholecalciferol[6].

We have recently measured the uptake of calcium by the isolated sarcoplasmic reticulum (SR) of the psoas muscles of vitamin D-deficient and vitamin D-supplemented rabbits and our results provide direct evidence of a biochemical effect of vitamin D deficiency on striated muscle.

Weanling Dutch rabbits were fed a vitamin D-deficient diet (General Biochemicals, Laboratory Park, Chagrin Falls, Ohio) from the age of 4 weeks (D− rabbits). Their litter mates were given the same diet supplemented with vitamin D providing 10–13 IU vitamin D_2 d^{-1} (D+ rabbits, 'controls'). The D− rabbits became weaker than the controls, and showed histological and biochemical evidence of rickets, (plasma calcium 7.9 ± 0.4 mg per 100 ml; control 12.8 ± 0.4; mean ± s.e.m.). At the end of the period on the diet (5–7 weeks), pairs of D− and D+ animals were killed and both psoas muscles were quickly excised from each animal and placed in ice-cold buffer (5 mM histidine, *p*H 7.0; 0.1 M KCl). Individual muscles were homogenised and an SR fraction isolated, sedimenting between 8,000 and 70,000*g*, by differential centrifugation, according to Martonosi, Donley and Halpin[7], except that only one extraction in 0.6 M KCl was carried out. The final SR pellet was resuspended in 5 mM histidine, *p*H 7.0, containing 0.1 M KCl and 5 mM dithiothreitol. Electron microscopy showed little contamination of the vesicular material by either sarcotubular fragments or mitochondria. The rate of calcium uptake by SR was measured on the day after isolation by Millipore filtration assay (Table 1)[8,9]. Preliminary experiments showed that calcium uptake was dependent on ATP. Its rate varied linearly with SR protein concentration (10–40 μg protein ml^{-1}), and with time for the first 90 s of the reaction. The rate of calcium uptake over the first minute by the SR from each muscle was measured in duplicate at three different protein concentrations. As the mean value obtained from the psoas muscle on each side of any individual animal was not significantly different, the result given in Table 1 is the average value for each animal and represents the mean of 12 measurements—6 on each psoas muscle.

TABLE 1 Rate of calcium uptake by SR isolated from the psoas muscles of D+ and D− rabbits

Pair No.	Calcium uptake (μ mole per min per mg SR protein)	
	D+	D−
1	1.94	1.42
2	2.13	1.88
3	1.88	1.68
4	2.06	1.55

Calcium uptake was measured in 3 ml of medium containing 20 mM histidine, *p*H 6.4, 100 mM KCl, 5 mM Mg^{2+}, 5 mM oxalate, 5 mM ATP, 100 μM $^{45}CaCl_2$ and 10–40 μg SR protein ml^{-1} at 25 °C. The reaction was started by the adding of $^{45}CaCl_2$ and stopped, after 60 s, by passing an 0.1 ml sample, diluted with 0.5 ml of 5 mM histidine, *p*H 7.0, 0.1 MKCl buffer, through an HA Millipore filter (pore size 0.45 μm). The rate of calcium uptake by the SR was calculated from the ratio of the amounts of ^{45}Ca, determined by liquid scintillation counting, retained on the filter and in the filtrate. Blank values were obtained in the absence of SR protein. The values for each rabbit are the average of twelve separate determinations (see text).

In the D− rabbits the rate of calcium uptake by the SR was lower in all experiments than in the D+ controls. The mean difference between the pairs of D− and D+ rabbits is significantly different from zero ($t = 7.27$; $P < 0.001$), and the difference between the mean rates of calcium uptake for the two groups is also significant ($t = 2.25$; $0.05 > P > 0.02$). In some experiments the SR samples were incubated for varying times at 37° C and the rates of calcium uptake subsequently measured (Fig. 1). The SR from the D−

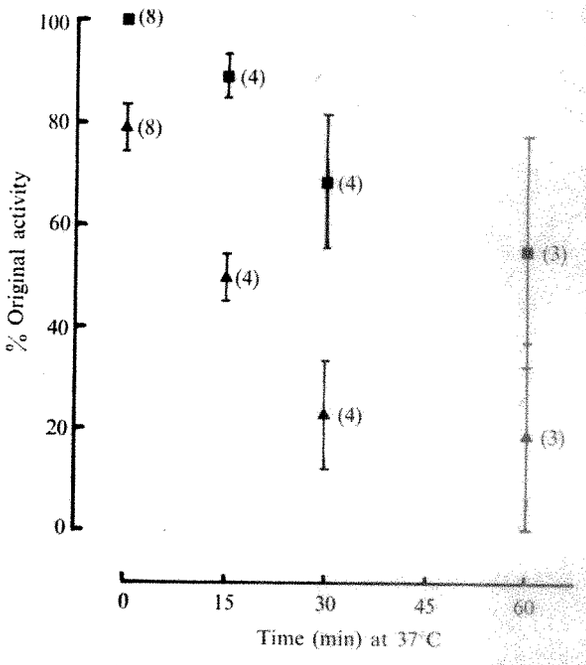

FIG. 1. Percentage of initial rate of calcium uptake by SR after incubation at 37°C. The results are expressed as a mean % ± s.e.m. of the rate of calcium uptake of the paired control when first measured. Numbers of animals are given in brackets. ■, D+; ▲, D−.

animals lost its ability to concentrate calcium more rapidly than that from the D+ controls.

No consistent differences were observed by the linked spectrophotometric assay of Horgan, Tume and Newbold[10] in the rates of either the Mg^{2+} or the Mg^{2+}–Ca^{2+}stimulated ATPase between the SR isolated from the two groups of animals. In an initial repletion experiment three oral daily doses of 100 IU of Vitamin D_3 were given to one of a pair of D− rabbits. The rate of calcium uptake by the SR from the repleted rabbit was higher than that of the D− rabbit (1.39 as against 1.09 μmol Ca per min per mg SR protein). The activities of the Mg^{2+} and Mg^{2+}–Ca^{2+} stimulated ATPase were again similar.

In rabbits up to the age of 8 d it has been shown that both muscular activity and age affect the rate of calcium uptake by SR[11]. The subsequent changes until maturity are not known. In our rabbits the animals in each pair were exactly the same age and this showed no apparent relation to the rate of calcium uptake by the SR; there was also no clear difference in their spontaneous muscle activity although the D− animals were weak and hypotonic. We consider that the difference in calcium uptake between the D− and the D+ animals is due to an effect of vitamin D deficiency on the muscle itself rather than on its nerve supply. In rats denervation may increase (rather than decrease) the rate of active calcium transport by the SR of slow muscle, but not of fast, to which group the psoas belongs[12].

How vitamin D deficiency affects SR is not known. As no differences were seen in the Mg^{2+} and Mg^{2+}–Ca^{2+} stimulated ATPase activities of the SR from the D− and D+ rabbits, the observed alteration in the rate of calcium uptake may be a result of changes in the calcium transport coupling system[11–14], and similar 'inefficient' SR has been isolated from dystrophic muscle[14].

There are clearly many possible calcium dependent mechanisms in muscle upon which vitamin D might have an effect. Our results provide support for the inclusion of muscle as another target organ for vitamin D.

This work was supported by a grant from the Muscular Dystrophy Group of Great Britain to R.S. We are grateful to Dr M. Owen for the D− and D+ rabbits.

Site and mechanism of water vapour uptake from the atmosphere in ixodid ticks

Uptake of water vapour from subsaturated atmospheres has been demonstrated in a variety of terrestrial insects and mites but no previous effort to identify the site and mechanism has been completely conclusive. The tracheal system, the rectum and the general body surface have variously been proposed in specific studies.

Noble-Nesbitt[1] found that occlusion of the anus of the insect *Thermobia domestica* (Packard) prevented recovery of an experimentally imposed body water deficit and he suggested that the site of vapour sorption is in the rectum. The tick *Dermacentor variabilis* (Say), however, was not impaired in this ability by blocking the anus[2,3].

The present investigation deals with the site of water vapour uptake in the ixodid tick *Amblyomma variegatum* (Fabricius) and considers a possible uptake mechanism. Unengorged adults, both males and females, were used between 8 and 20 weeks after ecdysis. During this period there were no waste products; weight and water content (60% of total weight on the average) showed no significant changes at constant conditions of 20° C and 93% relative humidity (r.h.) This humidity was well above the critical equilibrium humidity (found to be between 80% and 85% r.h.) of the adults. At 20° C, ticks could be handled without using carbon dioxide anaesthesia.

Ticks exposed to 33% r.h. and 20° C for 4 weeks lost 17%–19% of their initial weight or 28%–31% of their initial water mass. Subsequently, in groups of 10 ticks each, the following parts of the body were covered with paraffin wax (melting point 42° C–44° C): the anus, the complete dorsal surface and the mouthparts. A control group of 20 ticks remained without paraffin treatment. During the ensuing exposure to air of 93% r.h. and 20° C the body water mass increased at 3.0 ± 0.7% d^{-1} in the control ticks, 3.4 ± 0.6% d^{-1} in those with the anus covered, 3.1 ± 0.8% d^{-1} in those with the dorsal surface covered; those ticks with the mouthparts covered lost 0.3 ± 0.1% d^{-1} of their body water for a period of 4 weeks.

The effect of covering the mouthparts is also evident in hydrated ticks in equilibrium with 93% r.h. Of a group of 20 ticks, those untreated were able to maintain equilibrium weight in air of 93% r.h. and 20° C; but those with the mouthparts covered lost 0.2 ± 0.1% of their body water each day during an observation period of 7 weeks.

To show that the application of paraffin wax and the contact between the mouthparts and the applied wax had no adverse effects on water uptake, the following experiments were performed. In one group of ticks, dehydrated as above, only the distal half of the mouthparts was painted with paraffin wax such that both the dorsal space between the chelicerae and the lateral spaces between the hypostome and the chelicerae provided paths between the surrounding air and the buccal cavity. These ticks were able to increase their body water, comparable with that in the control group, at a rate of 2.9 ± 0.5% d^{-1} in air of 93% r.h. and 20° C. When the wax was removed manually from 10 ticks that had suffered loss of weight with their mouthparts sealed

with wax, vapour sorption commenced immediately in each. Moreover, in most ticks with sealed mouthparts, beginning after approximately 4 weeks the wax cover progressively softened from the inner surface (perhaps because of ejected saliva), gradually detached itself from the mouthparts and after about 5 weeks could be removed in one piece. Accompanying this process, the rate of gain of body water mass increased gradually from $\sim$ 0.5% d^{-1} in the early stages of loosening to $\sim$ 3.0% d^{-1} after the removal of the wax cover. From these experiments we can conclude that blockage of the mouth prevents net water gain from the atmosphere in *A. variegatum*.

That water vapour actually passes through the mouthparts was shown in an experiment which did not require blockage of the mouthparts with paraffin wax. For this purpose the mouthparts of a dehydrated tick were inserted through a wax-coated parafilm membrane up to the base of the palps. This membrane was clamped between the open ends of two glass tubes (inner diameter 5 mm, length 20 mm) such that the mouthparts projected into one tube and the rest of the body into the other. The contact line between the two tubes and the penetration point of the mouthparts through the membrane was carefully sealed with melted paraffin wax. The opposite ends of the glass tubes were closed by parafilm membranes coated with paraffin wax. By injecting the needle of a microlitre syringe through these parafilm membranes, 1 μl of saturated KNO_3 solution (which provided a humidity of 93% at 20° C) was placed on the wall of each glass tube, adjacent to but not touching the tick. The membranes were subsequently repaired. After 28 h the drop of KNO_3 solution adjacent to the mouthparts had changed to a moist crystal of KNO_3, whereas that in the tube containing the rest of the body seemed to be unchanged. The possibility that vapour inadvertently escaped to the surrounding air was completely precluded by holding the assembly in a container over KNO_3 solution. This experiment brought the same result when repeated with five different ticks. The rate of decrease in the the volume of the solution adjacent to the mouthparts was estimated to equal in magnitude the rate of net water gain from air of 93% r.h. and 20° C that had been measured in similarly dehydrated ticks.

Active uptake of water vapour, either to acquire or to maintain equilibrium water mass, takes place through the mouthparts in the ixodid tick *A. variegatum*. Since similar results have been obtained when these experiments were performed on adults of *Rhipicephalus bursa* (Can. et Fanz.), *Hyalomma anatolicum excavatum* (Koch) and *Hyalomma schulzei* (Ol.), it may be suggested that active uptake of water vapour proceeds through the mouthparts in all ixodid ticks.

There is some evidence for a significant role of the saliva in the mechanism of vapour uptake as shown by the following observations. Severely dehydrated adults of *A. variegatum* (desiccated to 50.6 $\pm$ 11.3% of their initial water mass) have been observed to secrete through the mouthparts a clear fluid which accumulated between the hypostome and the palps and quickly dried to a white crystalline solid in the desiccation chamber, but when these ticks were transferred to humidities greater than the critical equilibrium humidity the crystalline solid dissolved in absorbed water and the liquid was subsequently imbibed. These crystals occurred only between the hypostome and the palps and so the passage to the mouth remained open. Moreover, the clear fluid could be observed in the buccal cavity and the salivary ducts of all ticks (regardless of water status) after removal of the chelicerae and the dorsal part of the capitulum.

The crystalline solids, described above, were collected from the mouthparts of dehydrated ticks and exposed to a series of different humidities. The substance remained unchanged in humidities less than 75%; at 75% r.h. it became moist without dissolving, above 80% r.h., however, it took up substantial amounts of water within a few seconds and finally dissolved. Recrystallisation occured when the dissolved substance was transferred to relative humidities less than 75%. It should be noted that the lower limit of water uptake by the crystalline solids corresponds with the critical equilibrium humidity of the species.

Preliminary chemical analysis of the crystalline substance has identified high concentrations of sodium and potassium; anions have not yet been identified. To obtain greater amounts of secretion from the mouthparts 0.5 μl of a 3% isotonic solution of pilocarpin was injected into unengorged adults which were in equilibrium with 93% r.h. at 20° C. This immediately led to copious salivation. The secretion obtained was, however, different from that described above. It lost water only very slowly at low humidities and did not exhibit the dramatic water uptake at high humidities. Furthermore, it contained an immiscible viscous, milky cement substance which has been described for ticks in connection with attachment to a host.

This study shows that active uptake of atmospheric water vapour in ixodid ticks proceeds through the mouth. It may well be related to hygroscopic properties of salivary secretion. Resorption of the absorbed water could possibly take place in the gut, although the remarkable abilities of the salivary glands in handling water[4–8] should be kept in mind. Further experiments on the uptake of water vapour in ticks are in progress.

We thank Dr E. Schein, Institut für Parasitologie und Tropenveterinärmedizin der Freien Universität Berlin, for supplying the ticks, and Professor E. Wiesenberger, Institut für Anorganische Chemie der Freien Universität Berlin, for chemical analysis of the salivary secretion.

Is texture-density contrast an inhibition or an adaptation?

MACKAY'S recent experiments on texture-density contrast[1] are an interesting contribution to the current, rapidly-growing literature on 'feature-specific inhibition' in the visual system. There have been suggestions, based mainly on psychophysical evidence, that there is mutual inhibition between 'channels' selective for binocular disparity[2], orientation[3,4] and spatial frequency[5,6]. It is known that many neurones in the visual cortex respond selectively to particular values on these three dimensions[7–9] (as well as others, such as direction and velocity). Our knowledge of lateral inhibition at earlier levels in the visual pathway indicates that mutual inhibition between

such multi-channel neurons would account for a wide range of visual effects.

Following a previous suggestion[10], MacKay has proposed a new type of neurone, responding as a monotonic function of texture density, with inhibition between such units playing an important perceptual role in enhancing local density gradients (such as the edge between two surfaces of different material, or at different distances). Before accepting the existence of 'texture-density contrast' as an important phenomenon, however, we must be sure that MacKay's observations cannot be explained in terms of known effects.

Successive contrast between gratings or textures of different densities (the 'spatial frequency shift') is well documented[11–13]. After inspection of one pattern, a subsequently viewed finer pattern looks even finer, a coarser one even coarser. It is particularly important when doing experiments aimed at showing simultaneous contrast to show that the effects obtained are not simply the after effects of adaptation[14,15]. For example, when viewing MacKay's demonstrations[1] (Fig. 5 of ref. 1), if fixation drifted onto the background, even for a second or two, an after effect would be expected when the test pattern was refixated.

MacKay himself reported that the contrast effect was enhanced by moving the figure up and down while the eye was held stationary. This of course suggests an explanation in terms of adaptation, as fixation was alternating between the background and test patterns. Because MacKay presented no formal data, and little information on viewing conditions, it is impossible to assess the likely extent of adaptation in his experiments.

Turning to his demonstrations, the reader is faced with some difficulties in judging the phenomenon. Figure 5*a* cannot properly be assessed, as it contains a serious artefact. The two outermost lines in the left half of the test grating are in contact with lines in the background grating, and so actually are wider! Another error occurs in Fig. 2*a*, which contains three regions of supposedly equal frequency. On taking a ruler to it, one finds 8 cycles cm^{-1} in the central and right-hand regions, but about 8.5 cycles cm in the left-hand region. This difference of 6% is in the same range (5-10%) as the effect claimed. The reader cannot tell whether it is an error in photographic reproduction, or was present in the original display.

I have obtained reports from several observers, who agreed that the dot pattern of Fig. 5*b* gave a noticeable contrast effect on immediate viewing, but most were unable to make a judgment on the random texture of Fig. 5*c*.

About a year ago, I did some experiments also aimed at showing spatial-frequency contrast, with stimuli very similar to MacKay's Fig. 5*a*. The background patterns were vertical, high-contrast sinusoidal grating photographs of 3.5 and 7 cycles per degree. The two test patterns were of much lower contrast, at 5 cycles per degree, each subtending 1.5° × 1.5°, one vertically above the other, separated by a grey strip 0.25° wide. They were presented in a tachistoscope, with the test patterns either both vertical or both horizontal, for 0.5, 1, or 2 s with instructions to fixate a mark centred between the test gratings, and to report whether the upper or lower test grating appeared to have the broader bars and/or wider spacing.

In the first experiment, the background pattern was left unchanged over a sequence of 120 trials for each of four subjects. The result for vertical test gratings was an average of 78% reports in favour of contrast, while for the horizontal test, only 57% (where 50% represented chance).

Although the trials were brief, specifically to avoid adaptation, I then realised that adaptation to the background could have been building up over trials. Five more subjects were run, with 0.5 or 1 s presentations and the background patterns were interchanged after each trial to balance out any spatial adaptation. The results in this series were much more variable, and did not deviate significantly from chance (48% with test vertical, 37% with test horizontal). I concluded that a spatial-frequency, or texture contrast effect did not exist, when adaptation was properly controlled for.

In view of MacKay's demonstration with dot textures, it now seems possible that a texture-contrast effect may exist in some circumstances. Much more controlled experimentation is required, however, to demonstrate that it has any generality, and that it is not due to the after-effects of adaptation to the background pattern. Of course, the spatial-frequency shift (after effect) may itself play a role in enhancing a texture discontinuity, but it does not need a new type of neurone or process to account for it.

PROFESSOR MACKAY REPLIES: Dr Georgeson[1] could easily have disposed of most of his doubts.

The test strips in my demonstrations of simultaneous space-frequency contrast[2] had a subtense of between 1° and 2°. There is no difficulty in keeping one's fixation on the horizontal midline of such a broad strip, yet an effect of about 10% is then measurable even with Fig. 1, which has no background lines at the ends of the strip. Slight vertical oscillation of the figure enhances but is not at all essential to the effect.

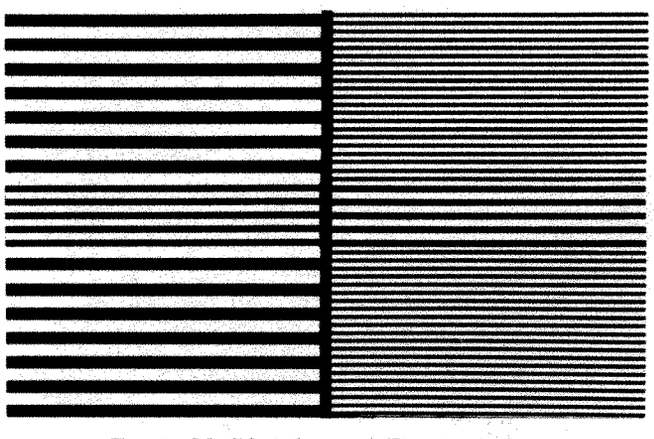

FIG. 1 Modified form of Fig. 5*a* (ref. 2).

The effects for some O's are stronger immediately on viewing than after a minute or so of inspection. This adaptation

is opposite to that which might be expected on Georgeson's hypothesis.

What Georgeson describes as a 'serious artefact' is easily evaluated. With movable test strips, the contrast effect is seen regardless of their location relative to the background stripes, and Fig. 1, free of the allegedly 'serious' artefact, is just as effective as my original figure (Fig. 5*a* ref. 2).

The distortion of the line-spacing on the left of Fig. 2*a* of ref. 2 is regrettable; but it need not prevent the reader from checking the points made, which depend an (i) comparing the perceived spatial frequency of the central panel with that of either side panel, (ii) observing the effects of masking the transition regions, and (iii) comparing Fig. 2*a* with Fig. 2*b*.

(i) Only the left-hand panel was distorted; yet covering over this panel as far as the transition region (or indeed the whole panel) does not abolish the illusory frequency contrast between the other two panels.

(ii) Masking the transition regions, on the other hand, does abolish the illusion.

(iii) In Fig. 2*b*, the centre frequency of the middle panel as printed (8.25 cycles cm^{-1}) is still higher than the average for the other two panels (7.75 cycles cm^{-1}); yet it is perceived as matching them when the transition regions are visible, and not when they are masked.

In view of all this, Dr Georgeson's own negative findings with different stimuli under different conditions scarcely justify his conclusion.

Mid-Precambrian prokaryotes(?) from the Belcher Islands, Canada

SPECULATION about the Precambrian biosphere and about evolutionary history is slowly being substantiated and modified by new palaeontological evidence from many regions. I present here more such evidence—a preliminary report of the discovery of a well preserved stromatolitic microflora from cherty dolostones of the Belcher Supergroup in Hudson Bay. This microflora may provide important information about the stage of algal evolution about 2,000 Myr ago, and about stromatolite genesis. Futhermore, the well preserved cellular biofabric facilitates description of the development of primary stromatolitic microstructure permineralised *in situ* by silica, and its subsequent modification (Fig. 1*a*) by carbonate diagenesis into a secondary microfabric, which is important in stromatolite taxonomy.

This fossil microflora contains the oldest known, well preserved palmelloid algal colonies, and their mode of growth and occurrence in stratiform and domanl stromatolites confirm that non-filamentous algae are important in the formation of Aphebian stratiform stromatolites. Cells have well differentiated morphological details, such as protoplast, cell wall, and a laminated envelope (Fig. 1). Moreover, two of the taxa in these colonies contain dark inclusions in the protoplast. In the Bitter Springs microflora[1] and elsewhere similar structures have been interpreted as nuclei, and the fossils as eukaryotic, and the same evidence could be used for a similar interpretation of the Belcher material. On the other hand, the dark bodies may be granular inclusions of prokaryotes, or plasmolytic artefacts[2] of prokaryotes or eukaryotes, or possibly diagenetic relics.

Microfossils and possible microfossils are already known from the Belcher Islands[3,4]. Those reported here occur in black chert layers and pockets in laminated, stromatolitic carbonates of the Kasegalik and McLeary Formations in the lower part of the Belcher Supergroup[5,6]. These rocks form part of an Aphebian miogeoclinal sequence of sedimentary and volcanic rocks belonging to the Belcher Fold Belt, part of the larger Circum-Ungava geosyncline, the principal phase of deformation of which embraces the period of the terminal Aphebian Hudsonian orogeny. The latest available isotopic age determinations[7], based on the Rb-Sr whole-rock isochron method ($\lambda^{87}Rb = 1.39 \times 10^{-11}\ y^{-1}$), indicate a minimum of 1800 Myr for the sequence yielding the microfossils. Basement is not exposed in the Belcher Islands, but correlative units along the Manitounuk-Nastapoka arc to the east lie on Archaean basement which is 2,500 Myr old[8]. The general geology and geological history of the Belchers has been described by Jackson[4,6]. A more detailed study of the stratigraphy, sedimentology and palaeontology of the Belcher rocks is in progress (R. T. Bell and H. J. H., in preparation); this should lead to a better understanding of the Aphebian record there.

The new Belcher microfossils were obtained from the upper parts of the Kasegalik Formation on an unnamed island at the northern end of Churchill Sound (56°29.5′N

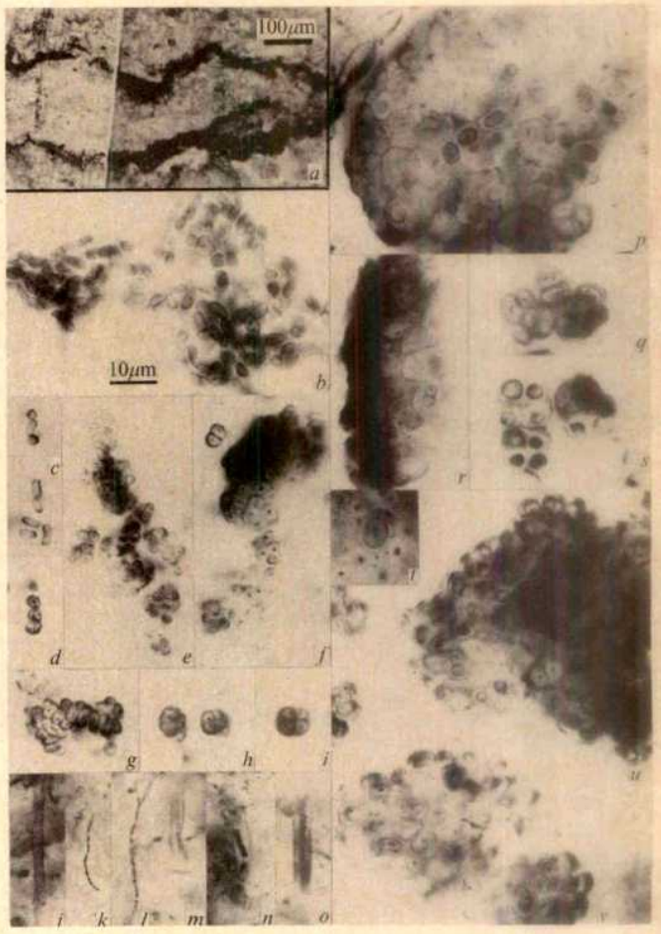

FIG. 1 Optical photomicrographs of stromatolitic lamellae and microfossils in thin sections from the Kasegalik Formation of the Belcher Islands. Compare the effects of carbonate diagenesis on dark, organic lamellae in the left third of (*a*) with the unaffected parts in silica matrix to the right. Magnifications for (*b*)–(*v*) are identical, and are ten times that for (*a*).

79°30.2'W), and from several levels within the McLeary Formation on Flaherty Island, along the south shore of Eskimo Harbour. Both formations show evidence of peritidal deposition. The geological setting of the stratiform and domal algal mats of the two formations, yielding the palmelloid colonies illustrated in Fig. 1, is probably a large sebkha/algal flat/shallow basin complex, as attested by abundant desiccation features, laminated structure and the presence of halite and sulphate casts[9].

In mode of preservation, level of organisation and palaeoenvironmental setting, the new Belcher assemblage compares with other Precambrian assemblages such as those in the Gunflint or Bitter Springs cherts, but it is distinguished from them by its relatively small diversity of species. This probably reflects its mature biocoenotic character of uniform, environmentally restricted algal mats, rather than a lack of diversity of organisms existing about 2,000 Myr ago.

The half-dozen new microfossils and the stromatolites will be described formally elsewhere after further investigations. For this report the microfossils are assigned to the following categories. (1) Loose aggregates of oblong bacterioid cells without inclusions and without envelopes, 1.5–2 μm wide and 3–4 μm long (Fig. 1*b* and *c*). (2) Colonial unicells in loose clumps; composed of spheroidal cells averaging 2 μm in diameter, with single dark inclusion and without envelope (Fig. 1*d–i*); some cells show evidence of division. (3) Compact, coherent colonial clusters and crinkled, pustulose stromatolitic layers composed of ellipsoidal to ovoidal cells with well differentiated protoplast, 3–5 μm in diameter, dark inclusions 0.5 μm across, cell wall, and a thick sheath which may be laminated around some cells and with an external form which is polyhedral because of close packing. (4) *Eomycetopsis*-like tubes 3–4 μm across, possibly representing empty sheaths of filamentous algae (Fig. 1*j*). (5) *Gunflintia*-like trichomes less than 1 μm across and up to 40 μm or more long, made up of a chain of dark spheroidal bodies (Fig. 1*k* and *l*). (6) Filaments composed of a chain of dark bodies 1 μm across, surrounded by a sheath 3–4 μm in diameter (Fig. 1*m-o*). This type may represent more nearly complete individuals composed of forms (5) and (6).

The biological affinities of these fossils are not known, although an algal origin for the colonies seems the most plausible. Nor is it established whether the different unicellular types are really different organisms or whether two or more represent different ontogenetic or degradation stages of the same species.

Of special interest are the types with dark bodies (Fig. 1*d–i*; *p–v*), with well defined protoplasts. Similar inclusions, though in larger microfossils, from the Late Precambrian have commonly been interpreted as nuclei[1]. Without these bodies, the size range and morphology would invite comparison with such modern blue-green algae as *Chroococcus*, *Microcystis*, *Entophysalis* and *Gloeocapsa*. Recent experimental evidence indicates that such dark internal bodies may be entirely plasmolytic artefacts[2]. However, this does not necessarily mean that all microfossils with internal dark spots so far described should be reassigned to the prokaryotes: it provides an alternative explanation. Other possibilities are that the structures are remains of metabolically-functional organelles, vacuoles, intracellular symbionts[10], or diagenetic artefacts. Present evidence, therefore, is inconclusive as to whether the structures are eukaryotic or prokaryotes preserved at different stages of plasmolysis. Evidence against the eukaryotic nature of the microfossils is the small size of the cells, and the lack of other unquestionable eukaryotes from rocks older than 1,000–1,200 Myr, although microfossils with attributes suggestive of eukaryotic organisation have been reported from the Aphebian[4,11]. Nevertheless, it is possible that the evolution of larger, chlorophytic algae with normal eukaryotic organisation began with the development of nuclear bodies and organelles in primitive, cyanophyte-sized, ancestors at least 1,800–2,000 Myr ago; the Belcher microfossils would represent such remains.

I thank Dr R. T. Bell, Brock University, for logistic support and advice in the field, Mr D. Krause, settlement manager of Sanikiluaq, for facilitating work in the Belcher Islands, and Dr S. M. Awramik, Harvard University, for a copy of the text and slides accompanying the abstract cited in ref. 2. This investigation was supported financially by the National Research Council of Canada.

Erratum

Unfortunately during preparation for the printer the axes of Fig. 2 were wrongly labelled in the letter "Ion fluxes in disk membranes of retinal rod outer segments" by W. T. Mason, R. S. Fager, and E. W. Abrahamson (*Nature*, **247**, 562; 1974). The corrected figure is now shown.

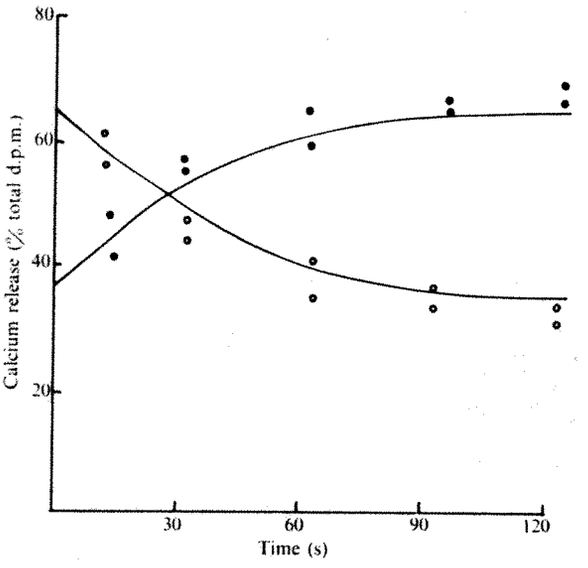

Fig. 2 Light-induced calcium release by sonicated bovine photoreceptor membranes over a time course of 120 s bleaching. Filled circles indicate percentage of Ca^{2+} in the extradisk space and open circles the percentage of Ca^{2+} in the intradisk space.

book reviews

Solid state

Theoretical Solid State Physics. By W. Jones and N. H. March. Vol. 1, *Perfect Lattices in Equilibrium*: pp. xvi+680; vol. 2, *Non-Equilibrium and Disorder*: pp. xv+681–1301. (Interscience Monographs and Texts in Physics and Astronomy.) (Wiley: London and New York, September 1973.) Each volume £14.75.

An introduction to Solid State Physics and its Applications. By R. J. Elliott and A. F. Gibson. Pp. xx+490 (Nature-Macmillan Physics Series) (Macmillan: London and Basingstoke, February 1974.) £5.95.

TEXTS on solid state physics are numerous. It is therefore pleasing to note the appearance of two new works for which substitutes are not already available. The two volumes by Jones and March give a comprehensive coverage of a large area of theoretical solid state physics and are directed toward professional theoreticians and postgraduate students. In contrast, the book by Elliott and Gibson is aimed at the undergraduate in the general area of material science and brings together the theory of solids and device applications.

The first volume of Jones and March includes band theory and crystal symmetry, collective effects in solids, lattice waves, spin and orbital magnetism, interactions of particles with a crystal. The second volume covers transport, optical properties, superconductivity, polarons and excitons, defects and disordered systems. Detail is developed in numerous appendices, and a set of problems and a basic bibliography are given.

In general the material is thoroughly covered and developed as far as more important current research papers. Techniques of many body theory are introduced in the text and developed in appendices, the fullest discussion being centred round the Coulomb interaction, though interactions involving phonons are also treated. The consequences of symmetry are also extensively discussed and an 83-page appendix on group theory is provided.

The chapter on band theory, typically, bridges the gap nicely between the limited treatment of a single volume treatise and the specialised monograph. Inevitably, for some sections, readers will prefer other texts. For an introduction to plasma effects and the electron-phonon interaction, I find Pines's *Elementary Excitations in Solids* clearer, although the present work does, with advantage, include detailed many body theory. Regarding the electron-phonon interaction, Pines's initial general survey establishes greater unity than the present separate discussions under phonons, transport and superconductivity.

A nice perspective is developed in the chapter on magnetism. The starting point is the general interacting electron Hamiltonian which leads to a study of the Heisenberg and Hubbard models and a clear appreciation of the approximations involved. The discussion of spin waves and magnetic phase transitions relates to neutron scattering theory which appears in the useful chapter on particles as probes for the study of solids.

Some topics have of necessity been omitted (polariton theory is one), and others chosen for only brief coverage: for example, infrared absorption under optical properties and the Kondo effect in the chapter on disorder. Otherwise this chapter is a full survey of a wide field of much recent activity.

This work, an extensive account of present understanding of solid state theory, is a valuable addition to the literature. The authors are to be commended for undertaking this mammoth task.

The opening two chapters of Elliott and Gibson discuss basic ideas of crystal structure and excitations. The reciprocal lattice is dealt with only briefly and the beginning student may need to refer to a more discursive text. The next two chapters cover lattice vibrations and electrons in bands. The basic theory of lattice vibrations is introduced, followed by neutron scattering results for various crystals, starting with the 'simple' rare-gas crystal and developing through more complicated types. The classification and comparison over a short space is particularly effective. Being of major importance in applications, the fifth chapter treats imperfections in some detail.

A survey of photon absorption over the range 10^{2}–10^{-3} eV in the section on optical properties puts the various absorption processes into perspective. The chapter finishes with optical emission and non-linear optics. The following two chapters deal with optical and microwave properties of free carriers, and transport which includes superconductivity and its applications. The ninth chapter is entirely device oriented (semiconductor junction devices) and the book concludes with theory and applications of magnetic materials. Problems and answers are provided.

Many students will find this book too demanding because of its conciseness in presentation of some basic theory. Hence it is unlikely to replace books such as those of Kittel or Dekker as a basic teaching source, although I expect it to be used widely in conjunction with these. On the other hand, the terseness in style does give the reader an excellent connected impression of the subject. The wood stands out clearly but the student may have to refer elsewhere for a delineation of some of the trees.

J. A. BLACKMAN

Unicellular eukaryotes

Protozoology. By Karl G. Grell. Pp. viii+554. (Springer-Verlag: Berlin and New York, 1973.) 107 DM; $43.90.

IN former times protozoology was considered to be a suitable subject by which students could be introduced to biology, presumably because, being single-celled animals, protozoa were thought to be simpler than so-called higher organisms, and from an evolutionary point of view they seemed primitive. Extensive courses describing many types of protozoa were commonly given and a number of solid textbooks were available, mainly in German, and largely, of course, of a taxonomic nature. Now all that is changed and few university courses treat protozoology in depth.

Protozoa are, however, important objects of study from a number of points of view. They provide admirable experimental material for many types of work, in genetics, nutrition, sexuality, behaviour, and so on. They combine the advantages of being single cells and also of being undoubted eukaryotes, that is, basically the same as cells of higher organisms. They can be used as models for the formulation and experimental testing of theoretical systems of cell organisation involving nuclei, various cytoplasmic components and the external surface. Finally, some protozoa cause exceedingly unpleasant diseases, some still very common and almost uncontrolled in large regions of the world.

The book by Karl Grell is, therefore, very welcome as it is the only one which attempts to discuss the subject in a modern context. Only about a quarter is given to taxonomy, the remainder

being devoted to a general treatment of morphology, cytology, genetics, nutrition, behaviour and so on. Sometimes indeed it seems that protozoology is really a non-subject, a miscellaneous assortment of different types of study on an extraordinarily diverse collection of organisms.

The excellent section on genetics, for example, is based mainly on studies with *Chlamydomonas* and *Paramecium* and includes a great variety of topics. The only feature which stands out is the relatively large amount of attention given to non-Mendelian heredity, involving chloroplasts, mitochondria, kappa particles and other odds and ends. A particularly detailed account of work on Foraminifera is given, reflecting the special interests of the author. On the other hand, important parasitic protozoa, such as the malaria parasites, trypanosomes, *Leishmania* and so on, seem to get rather less attention than they deserve.

The book is extremely well printed and beautifully illustrated, and can be thoroughly recommended to those who can afford it. English-speaking readers must be grateful to the author for writing the book in their language, (earlier versions were in German), though some, may find themselves, as I was, at times irritated and even baffled by some linguistic idiosyncrasies. On such occasions a little knowledge of German still helps.

G. H. Beale

Atmospheres of planets

Physics of Planetary Ionospheres. By Siegfried J. Bauer: Pp. viii+230. (Physics and Chemistry in Space: vol. 6.) (Springer-Verlag: Berlin and New York, 1973.) 78 DM; $35.10.

Dr Bauer has worked in the field of planetary ionospheres for more than fifteen years. Working at the NASA Goddard Space Flight Center he has been closely associated with many of the recent developments in the subject.

His book, intended as an introduction, develops logically from a discussion of neutral atmospheres, ionising radiations, chemical processes and plasma transport. In this respect it follows the pattern of many recent books on ionospheric physics. It differs from these in that at each stage it extends the discussion to the planets, particularly Mars, Jupiter and Venus. The space devoted to the other planets seems to be related (quite reasonably) to the thickness of their atmospheres.

In later chapters Dr Bauer discusses models of planetary ionospheres, wave propagation and experimental techniques. The treatment of the last two subjects is rather synoptic and the student may find it necessary to consult the many references for enlightenment. The last chapter gives details of the observations of planetary ionospheres and includes electron density profiles for Mars and Venus measured by the Mariner spacecraft. It is perhaps surprising that only nine pages are devoted to the discussion of these interesting results.

This book has many excellent qualities: the diagrams, tables and general layout are attractive and there is a comprehensive list of up to date references. The author is familiar with the Russian literature and his explanation of some of the Russian terminology will be useful to many. It has become standard practice in the United Kingdom to use SI units in scientific texts. Dr Bauer uses a mixture of c.g.s. and practical units but I found this no great disadvantage.

The author intended his book "to be an introduction to the subject for a new generation of space scientists and a compendium for the old". In my view he has been largely successful. But even at today's prices fifteen pounds is inordinately expensive for a book of 230 pages.

A. R. W. Hughes

Atomic time

The Measurement of Frequency and Time Interval. By L. Essen. Pp. v+55. (National Physical Laboratory: Teddington, December, 1973.) £1.

The rapid development of increasingly precise methods for the generation of specific (atomic) frequencies and their measurement has had a resounding impact on a vast range of theoretical disciplines and practical applications. Accurate control of frequency is a fundamental requirement of radio and it makes possible, for example, the Doppler measurement of rate of change of distance required in navigation and space research. Since 1967 the SI unit of time has been defined in terms of the frequency of a particular transition of the caesium atom, thus giving rise to the integrated reference time scale of International Atomic Time (TAI), obtained by the continuous summation of time intervals deduced from measures of frequency. Coordinated Universal Time (UTC), an approximation to UT1 (or GMT) and which differs from TAI by an integral number of seconds, is now the basis for civil time in most of the world; it provides direct synchronisation to about a millisecond, but individual atomic clocks may be compared with much higher precisions (tens of nanoseconds) making possible, for example, the almost direct verification of the predicted relativistic dependence of clock rate on speed and gravitational potential. A rather more practical application is Loran C for navigation.

This monograph, written by the acknowledged pioneer in the field, describes the basic principles and practical applications of the use of atomic transitions (or spectral lines) as standards of frequency. The treatment is simple and straightforward; the descriptions of the methods used at the National Physical Laboratory, given with explanatory diagrams and photographs, are exceptionally clear even to a layman in the field. Determinations of precision and stability are fully covered. Understandably the main emphasis is on the caesium definitive standard, but Dr Essen also covers working standards (commercial standards, which are portable, are now available with precisions of the order of 1 part in 10^{11}), standard frequency radio transmissions, and the techniques of the comparison of frequencies. His final chapter is devoted to the design and performance of resonance (particularly cavity resonator) frequency meters. It thus provides invaluable background information for the many concerned with the applications of these fascinating developments. But it seems that much of the text was written in 1972 so that those more directly interested in the latest work, especially at laboratories other than NPL, should refer to the technical journals.

Dr Essen devotes one short chapter to atomic and astronomical time, and refers briefly to the modified form of UTC introduced as from January 1, 1972. Although he refrains from saying so, it must now be generally agreed that the adoption in 1956 of the ephemeris second as the SI unit of time was a grave mistake: the astronomers were over-optimistic as regards the practical and theoretical difficulties of its determination, whereas the physicists were not agreed as to which of several possible atomic transitions should be used as the standard. Apart from confusion and change, the second of Ephemeris Time (introduced purely as a theoretical astronomical time scale) is not an approximation to the current value of the second of UT (which varies with the speed of rotation of the Earth), so that the preservation of its value in the 1967 unit results in an unnecessarily large rate of departure of IAT from UT. This has perhaps led Dr Essen to imply that the introduction of leap-seconds into UTC on the preferred dates of 30 June and 31 December would enable the modified time signals to be maintained within ± 0.7 s of UT1—so drastically contradicted on January 1, 1973.

In spite of this misunderstanding (due mainly to the shortcomings of CCIR Report 517) Dr Essen has a right to be proud of his contributions and of his readable and informative monograph.

D. H. Sadler

Attacking viruses

Selective Inhibitors of Viral Functions. Edited by William A. Carter, Pp. 376. (CRC: Cleveland, Ohio, 1973.) $39.95.

IT is the opinion of many animal virologists that, with one or two isolated exceptions, the successful treatment of virus diseases with specific anti-viral drugs is a subject which falls into the pipe-dream category. Optimists can be found, however, and the editor of this multi-author work clearly defines himself as one in his introductory remarks. He has assembled here a collection of reviews concerned with both laboratory and clinical aspects of specific anti-viral agents together with accounts of host reactions to viral infections and of immunisation against viral infections.

The natural recovery process from acute viral infections is dealt with comprehensively and concisely by W. E. Stewart. He clearly points out that it is still difficult to assess the relative importance of circulating antibody, cell-mediated immunity, interferon, and non-specific defence mechanisms. In the chapter on immunisation against viral infection, L. W. Marshall briefly discusses theoretical aspects and describes the viral vaccines and passive immunisation procedures currently used in human medicine.

A speculative article "Active Sites of the Animal viruses: Potential Sites of Specific Chemotherapeutic Attack" by W. M. Mitchell follows. I feel that this author's enthusiasm has rather carried him away from reality, and that non-specialist readers might imagine, for example, that the synthesis of biologically active human interferon by solid-phase methods was just around the corner. This impression, is, however, corrected by a chapter on interferon structure by R. Weil and F. Dorner. Other chapters on the effects of interferon, the molecular requirements for interferon induction, interferon induction by polynucleotides and non-nucleotide interferon inducers are contributed by E. De Clerq and W. E. Stewart, M. D. Johnston and D. C. Burke, A. K. Field and E. De Clerq respectively. It is apparent that one of the most important aims of interferon research—its purification to homogeneity—is proving an intractable problem.

The remainder of the book is concerned largely with synthetic and semi-synthetic anti-viral compounds and antibiotics. Amantadine hydrochloride and related compounds, arabinosyl nucleosides and nucleotides, and halogenated pyrimidines are discussed, largely in a clinical context, by C. E. Hoffmann, L. T. Chien, F. M. Schabel and C. A. Alford, and J. Sugar and H. E. Kaufman, and comprehensive accounts of the anti-viral properties of thiosemicarbazones, guanidine and 2-(α hydroxybenzyl) benzimidazole, rifamycin SV derivatives, and streptovaricins are given by W. Levinson, L. A. Caliguiri and I. Tamm, B. Moss, and D. M. Byrd and W. Carter. The book concludes with a short article by P. M. Pitha on the possibility of inhibiting virus growth by the use of viral genome analogues.

The quality of the contributions in this volume is generally high, although one or two early chapters show evidence of sloppy proof reading and reference checking. The book can be recommended as an up to date account of its subject, the comprehensive bibliographies which conclude most chapters being particularly useful.

T. H. PENNINGTON

Food for ruminants

Chemistry and Biochemistry of Herbage. Edited by G. W. Butler and R. W. Bailey. Vol. 1: pp. xx+639; vol. 2: pp. xiii+455; vol. 3: pp. xii+295. (Academic: London and New York, October 1973 and January 1974.) Vol. 1: £12; $36; vol. 2: £8; $25; vol. 3: £6; $17.

THESE volumes provide for the first time a comprehensive source of information on the chemistry and biochemistry of herbage defined as plant material excluding seeds or roots grown for feeding herbivorous animals.

Chapters 1-11 deal mainly with organic constituents of plants, free and bound amino acids, amines and ureides; proteins and nucleic acids; non-structural carbohydrates; structural carbohydrates; lipids; plant phenolics; lignin; alkaloids; cyanogenetic glycosides and glucosinolates; chlorophyll, carotenoid pigments and sterols; forage saponins. Most chapters follow a similar pattern describing chemical nature, classification, extraction from tissues and estimation of these compounds, amounts present in plants and their component parts, biosynthesis and amounts of components, for example amino acids in proteins and fatty acids in lipids.

Perhaps it would have been more logical to include chapters 1 and 2 of volume 2 on vitamins, and water in herbage, in volume 1, and chapters 12 and 13 in volume 1 on mineral composition of herbage and nutritional aspects of soil ingestion by grazing animals in volume 2, along with four chapters on mineral absorption and composition of herbage, mineral biochemistry of herbage, organic acids and their role in ion uptake, and cycling of minerals in ecosystems.

Commendably, a good deal of attention has been given to linking treatment of subject matter, for example in the above chapters on minerals, and in chapters on physiology of light utilisation by swards, growth senescence and stress, and organic reserves and regrowth. Further chapters in volume 2 deal with the biochemistry of photosynthesis, symbiotic nitrogen fixation by legumes, the nitrogen cycle of pasture ecosystems and genetic variation in herbage constituents, this last chapter making a fitting end to volume 2 and prelude to volume 3, in its consideration of problems encountered in breeding improved varieties and emphasis on the need to evaluate results against animal performance.

The more applied chapters of volume 3 deal with conservation of herbage as hay and silage, leaf protein as an animal and human foodstuff, digestion of pastures by ruminants and other herbivores, the feeding value of herbage and its evaluation by laboratory methods, and limitation to the productivity of the herbage-fed ruminant that arise from diet, including the effects of toxic components and metabolic diseases.

Advanced students, teachers and research workers will find here an invaluable source of information, for example on assessment of methods of extraction of compounds from tissues, and on areas where, because of paucity of information on herbage plants, recourse has been made to non-herbage tissues, thus pointing to the need for further research. Examples of this are the description of biosynthesis of lipid components in spinach, chorella and bacteria, detailed studies of isolated cellulose from wood and commercial fibres, the need to assume that *in vivo* formation and interconversion of carbohydrates in leaves and stems are probably similar to those in seeds and tubers, and the belief that protein synthesis in plant cells is essentially similar to the mechanism worked out for bacteria and mammalian cells. Attention is constantly focused on the need for further research, for example, in comparing information available on temperate and tropical herbage and in the search for methods of measuring the nutritive value of herbage.

An attractive feature of the work is that agronomists and plant breeders will find useful biochemical treatment of several subjects such as ensilage and ruminant digestion, biochemists will find limitless avenues for research, while the ruminant, the ultimate beneficiary, is frequently brought into the picture. A worthwhile attempt, attended by considerable success, has been made to bridge the all-too-wide gap which frequently separates pure biochemists and workers in agricultural science.

On the whole the work is readable and, bearing in mind the diverse nature of topics covered in what are, for the most part, review chapters with appropriate lists of references, a reasonably even standard of treatment is achieved.

A good deal more attention could have been given to some topics however. The vitamins, for example are covered in only 11 pages, with no mention of important modern aspects such as vitamin D metabolites and the tocotrienols, and little consistency in description of symptoms of deficiencies of individual vitamins. Again, although commendable efforts have been made to take examples from many countries, this has not always been achieved: in chapter 27 all tables of hay composition are taken from the United States.

The volumes are attractively produced and the text contains few typographical errors. Minor blemishes noted in volume 2 include reference to "some mineral, possibly pectin" (page 110) and an obvious omission on page 119 (par. 2). Arrangements of some tables could also be improved.

W. M. Ashton

NMR for enzymes

Nuclear Magnetic Resonance in Biochemistry: Applications to Enzyme Systems. By Raymond A. Dwek. Pp. xviii+395. (Clarendon: Oxford; Oxford University: London, December 1973.) £8.

During the past ten years many attempts have been made to apply nuclear magnetic resonance (NMR) techniques to problems of biological interest and the subject has reached the stage when a comprehensive textbook is required to summarise and appraise the advances in this area. Thus Dr Dwek's book is opportune and is all the more welcome because this first comprehensive text on the subject is also a very good book.

In the chapters devoted to protein spectra, protein-ligand binding and the use of paramagnetic probes in such systems, the book indicates the extent to which NMR spectroscopy can be used to obtain three-dimensional structural information in enzymes, to identify functional groups involved in enzymatic reactions and to investigate the role of metal ions and coenzymes in enzyme systems. Dr Dwek's book attempts to provide a balanced view of the usefulness of the NMR technique in some of these areas by considering both its possibilities and limitations.

Adequate background NMR theory is given to allow for the understanding of the many applications considered. Emphasis is given to the theory of relaxation, exchange and paramagnetic shifts and relaxation because many of the more successful applications rely heavily on these aspects of magnetic resonance. Fortunately, Dr Dwek's research interests are in these areas and this is evident in his authoratitive coverage of relaxation effects related to paramagnetic metals and spin-label probes.

The book is well illustrated throughout with clearly labelled diagrams (although the labelling on the AMX spectrum in Fig. 2.14 is incorrect).

It is a pity that the chapter on protein NMR spectra was not introduced with a detailed section on amino acids and peptides. The problems encountered in trying to determine conformational information for small peptides would have put into perspective Dr Dwek's statement that "in principle, it should be possible to obtain from the spectrum the complete structure of a protein in solution".

The chapter on carbon-13 studies neglected to indicate the potential for studying strongly bound ligands in slow exchange (using ^{13}C enriched ligands to overcome the protein background spectrum) and also the advantages of studying ^{13}C relaxation times.

These are however relatively minor criticisms of an excellent book which can be recommended to anyone interested in learning more about enzyme systems.

J. Feeney

Echo technology

Radar, Sonar and Holography. By Winson E. Kock. Pp. xvii+140. (Academic: New York and London, December 1973.) $9.50; £4.45.

This book is intended to introduce high school and college students to the technology of radar and sonar, the principles of holography, and the impact of holography on echolocation. Its explanations successfully avoid the use of mathematical concepts or formulations. The opening chapters introduce waves, coherence, interference, diffraction, near and far fields and zone plates, radiators and collimators. But the author does not, for example, derive the diffraction beamwidth of a slit from interference between its left and right halves, or explain the Rayleigh distance as the intersection of the near-field projected aperture and the divergent far-field beam.

Next the book outlines the principles of echolocation, and gives examples of conventional radars and sonars. There is, however, no mention of surface ducts, self or radiated noise, reverberation, or the uses of Doppler in sonar. There is a chapter on Doppler radar, but the Doppler effect is not explained. Though no reference is made to normal pulse-Doppler radars, dual-frequency systems are mentioned—without indicating that their Doppler effect is determined by the difference frequency.

Next the book introduces monochromatic optical, acoustic holograms, lucidly explained as a generalisations of the zone plate. This leads on to synthetic-aperture side-scanning aircraft radars, which are well described by analogy to sequentially-generated holograms. The basic commonality of different configurations could, however, with advantage, have been explained in terms of reciprocity and symmetry. The use of coherent optics to synthesise the high-resolution near-field radar picture is clearly delineated.

Thereafter the author introduces some rather dubious material: he implies that large-aperture real arrays are a special case of synthetic-aperture systems, and have become possible only with the advent of holographic processing. He suggests that the number of elements in a given array aperture can be reduced without loss. (A reduced hologram can cover the same total picture, but only with an appropriately reduced resolution and/or contrast.) He fails to equate the gain from a synthetic-aperture end-fire system to that from a conventional coherent Doppler integrator; indeed there is no reference to the equivalence of coherent integration in the space and time domains. After recognising the equivalence between moving target indication (that is velocity null generation) and end-fire directivity (that is, rearward directional null generation), the author spoils it by stating that MTI is restricted to targets moving directly towards the radar.

The book describes pulse compression —but fails to distinguish between power and energy, or to indicate how 'chirp' frequency modulation is handled in practice. The elegant technique of 'zone-plate' amplitude modulation for optical pulse compression is explained, but not the more usual pseudo-random modulation and correlation detection. In discussing phased-array systems, the author extols holographic techniques for receiver beam forming, without reference to the range dimension (echo delay), within-pulse scanning, real-time processing, or adaptive beam steering.

Though open to such criticisms in detail, the book is very readable and well illustrated. It gives clear concise explanations of some modern concepts which are not well covered in popular technical literature. There are a few slips in proof reading, editing, history and theory—but probably no more than usual.

I feel the link between holography and echolocation has been overemphasised. I would also have opted for a less catholic coverage of 'with-it' technology and assorted applications, to make room for more explanation of physical principles and practical constraints. But this may merely reflect my preference for a book aimed at a somewhat more sophisticated readership. The author has probably met his own objectives and those of his senior high school readers well enough.

Ralph Benjamin

matters arising

Calibration of the radiocarbon time scale

SIR,—The recently published paper by Clark and Renfrew[1] on calibration of radiocarbon dates is the latest in a series on this topic[2–5] by archaeologists who are rightly concerned by the uncertainties now involved in interpretation of data. Central to those papers has been the attempt to 'smooth' the bristlecone calibration curve of Suess[6] to negate 'kinks' and thereby ease interconversion of radiocarbon and calendar ages. Here I sound a cautionary note on such practices and question the validity of the smoothing methods. There is no dispute here over the detailed statistical techniques invoked by the various authors. The issue in question is the overworking of experimental data. There is little doubt that the methods employed are justified neither by the quality of the ^{14}C results nor by the present understanding of ^{14}C geochemistry.

The key issue is centred on the vital difference between the absolute accuracy and analytical precision off the ^{14}C measurements which comprise the bristlecone pine calibration curve. It is important to consider the inequality of these parameters. The error terms reported with ^{14}C data are derived essentially from the statistical ^{14}C counting error alone. To assess the real accuracy of the measurements, however, requires an answer to each of the following questions:

(1) Is the ^{14}C level of wood grown at an altitude around 8000 feet indicative of concentrations at sea level and at all other latitudes?

(2) Is the ^{14}C content of wood fractions other than the cellulose component necessarily a precise measure of atmospheric ^{14}C levels during wood growth?

(3) Can experimental unknowns, such as counter behaviour, contamination effects, human error, standardisation and half life uncertainty, be totally neglected? Furthermore, are systematic differences between ^{14}C laboratories possible?

To each of these questions there can, as yet, be no ideal answer. Comment can, however, be made:

(1) At the extreme altitudes where the Bristlecone Pine grows, the ambient cosmic ray neutron flux is approximately one order of magnitude higher than at sea level. Since these neutrons are the source of ^{14}C through the reaction $n + {}^{14}N \rightarrow {}^{14}C + p$, it is feasible that bristlecone pine wood could be non-representative of normal organic material. Whether through *in situ* ^{14}C production or variable atmospheric mixing, bristlecone pine ^{14}C levels could experience localised effects. Furthermore, there is already preliminary evidence that atmospheric ^{14}C levels may be latitudinally dependent. Thus Jansen[7] and Lerman *et al.*[8] have observed depletions of 0.5% to 2% in ^{14}C concentrations of southern relative to northern hemisphere wood.

(2) It has been shown with fair certainty that some chemical components of wood can be transported between tree rings[9]. Cellulose is chemically the most inert constituent of wood and, to minimise cross contamination, should be selected for precise ^{14}C analyses. Perhaps due to the limited size of samples, the major American laboratories engaged in time scale calibration do not take this precaution.

(3) It would be unrealistic to imagine that either systematic differences between laboratories or occasional freak results within one laboratory do not occur. There are many potential causes of such deviations.

The factors discussed here cannot be quantitatively assessed at present because of incomplete evidence. Only future research can clarify the situation and, for this reason, independent calibrations of the radiocarbon time scale, such as now being developed at Queen's University, Belfast, are of major significance. In the meantime a realistic approach to the available ^{14}C data is essential. In other words, besides the analytical error reported for each bristlecone pine ^{14}C analysis, there exists a further major error term to be considered. At present we cannot quantify it. Nevertheless, in view of the geochemical aspects of the factors mentioned, it would be unwise to attribute a degree of absolute accuracy less than $\pm$ 2% (2σ) to the bristlecone calibration curve (unless the archaeological specimen in question is a pinewood sample from an American mountain top and is pretreated and analysed by Suess). A 1% error in ^{14}C content corresponds to a radiocarbon age error of 80 yr so that, including reported analytical errors, it seems at present unjustified to attribute an accuracy of less than $\pm$ 200 yr to the calibration curve. In essence then the curve should be imagined not as a line but as a probability band of considerable spread (400 yr). Through this approach a realistic interpretation can be performed. Admittedly, the value of the calibration curve is severely reduced but this is the real situation which no mathematical manoeuvring should obscure.

Finally, I note that the simple approach of Suess, in adjoining ^{14}C data by hand, is in many respects preferable to smoothing operations by computer. Our need at present is for awareness of the limits of available data and for an increased availability of such results. Smoothing operations, in their role of rendering the experimental data remote, are contrary to this requirement. In addition, given the major error terms inherent in the curve, there is little reason for sophisticated mathematics. Kinks may well exist. The real existence of one such anomaly is beyond dispute[10]. It is questionable therefore whether at this time it is objective to smooth them out.

So I urge patience and restraint. Calibration, if performed at all, cannot yet be as quantitative as would be desired. There can be no justification for the delusion that major uncertainties do not exist. Over interpretation of the calibration curve for archaeological purposes is, for the time being, unwarranted.

Yours faithfully,

M. S. BAXTER

SIR,—Clark and Renfrew[1] state that "the hypothesis of a common calibration curve for the bristlecone pine and Egyptian data over the time period 3100 BC to 1800 BC is not contradicted and suggestions to the contrary are not well founded". But according to Fig. 2 of ref. 1, all but two of the 14 Egyptian data points for the period 2200 BC to 1800 BC indicate ^{14}C dates that are less recent than indicated by the curve shown for the bristlecone pine, on average by one or two centuries. Consequently the statistical conclusion is difficult to accept; this viewpoint was put to one of the authors of ref. 1 by McKerrell at the 1973 Oxford Archaeometry Symposium, in support of his contention[2] that the bristlecone pine calibration is not consistent with the Egyptian data; but no explanation of the apparent paradox was then offered.

A close inspection of the figure gives an explanation. In the period 2100 BC to 1900 BC there is a substantial difference between the bristlecone pine curve and the tree ring data points that were used for the statistical analysis; this difference is in the same sense as for the Egyptian data. So the analysis by Clark and Renfrew cannot be held to contradict McKerrell's contention.

The tree ring data were taken from the unpublished thesis of Houtermans[3] and comparison of these with the data points shown by Suess on the bristlecone pine curve[4] confirms that there are differences between the two sets; since both sets originate from the same measurements one must presume that corrections have been applied to one set which have not been applied to the other. In the absence of other indications it seems reasonable to accept the published data rather than the unpublished. It is also relevant that using either of the bristlecone pine curves put forward by the Pennsylvania[5] and Arizona[6] radiocarbon laboratories (which incorporate the Suess data with later measurements) the Egyptian ^{14}C dates shown for ~ 2000 BC are still significantly less recent than bristlecone pine ^{14}C dates, though by not quite so much.

Yours faithfully,

M. J. AITKEN

Research Laboratory for Archaeology, Oxford University, 6 Keble Road, Oxford

DRS CLARK AND RENFREW REPLY: We agree with many of the points made by Baxter and in a paper now in the press[1] discuss the substantial statistical problems involved in constructing an adequate calibration curve from the data available. But the construction of a calibration curve was not, as Baxter seems to imply, the purpose of our recent paper[2]. Instead an evaluation was sought of the general applicability of the bristlecone pine data and their associated radiocarbon dates. The radiocarbon dates obtained from dendrochronologically dated bristlecone pine samples will match radiocarbon dates from historically/archaeologically dated Egyptian samples only if satisfactory answers could be given to his three questions: a precise equivalence would give exactly the independent corroboration which he is seeking. In fact, although the two sets do not contradict within the limits of their associated errors, the match is an inexact one because of the magnitude of those associated errors.

There should be no question here of overworking experimental data. The procedure used was to present, apparently for the first time, a formal analysis of the consistency of the determinations from different laboratories, working always through a consideration of the measurement errors involved (both as reported by the laboratories themselves, and as established from replicate analyses). Is this not in fact the only acceptable way of comparing two independent data sets?

The geophysical problems which Baxter indicates are not new, and will only be answered by statistical analysis of existing data and by the gathering of new data in such a way that it will be susceptible to statistical analysis. He is certainly right to stress that the appropriate form of the calibration curve is not yet clear, and that an error of perhaps ±200 yr is to be associated with the curve[3].

Aitken is correct that the data presented by Houtermans and by Suess are not in precise agreement: we chose to use the former because they were more recent and did not have to be read from a graph. Aitken's reference to Fig. 2 of our paper is not, however, to the curves used by us to compare the bristlecone pine and Egyptian data, but to Suess's original curve presented there for purposes of comparison only. If the data points of Fig. 2 are compared with the curves derived from those data, there is no contradiction. Consider, for example, the least-squares straight line. If the hypothesis (of a common calibration curve) is correct, one would expect roughly half of the data points to lie below this line. Inspection of Fig. 2 shows that, between 2200 and 1800 BC: (i) 5 of the 14 Egyptian points are below this line; (ii) 10 of the 19 bristlecone pine points are below this line.

Such a distribution of the 14 Egyptian points is not unusual; the probability of five or fewer points out of 14 being below the line is about 0.20 (from the Binomial distribution), so that there is no reason to doubt on this basis that the Egyptian points satisfy the same calibration relationship as the bristlecone pine data. The same argument could be applied to the entire interval from 3000 to 1800 BC. Figure 2 shows that 23 of the 52 Egyptian points lie below the fitted straight line, whereas 27 of the 57 bristlecone pine points lie below this line. One could hardly expect to get much closer to 50% than that.

It remains our conclusion that, on the basis of the available data considered, and within the error limits discussed (themselves unfortunately wide), there is no contradiction between the Egyptian and bristlecone pine data. This is an important conclusion since for some parts of prehistoric Europe the calibrated radiocarbon chronology differs by as much as 2,000 yr from archaeological chronologies put forward before the application of radiocarbon dating. At the same time, as Baxter rightly stresses, the error limits are large, and much more work will be needed before the form of the appropriate calibration curve will be known with precision.

Na^+ transport defect in cystic fibrosis

SIR—Using the technique of ^3H-ouabain binding to isolated cells Quissell and Pitot concluded that the Na^+–K^+ ATPase functions normally in fibroblasts from cystic fibrosis patients[1]. However this finding may not be very revelant to the Na^+ transport defect occurring in this genetic disease.

The Na^+ transport abnormality in cystic fibrosis seems to be confined to exocrine glands[2]. It is unknown at present whether the defect resides in an active or passive transport step of the cation. At least with isolated sweat

gland tissue[3] and erythrocytes[4] from cystic fibrosis patients, Na^+–K^+ ATPase activity has been found to be normal. However a decrease in the ethacrynic acid-sensitive efflux[5,6], a Na^+ exchange mechanism[5], has been reported in cystic fibrosis erythrocytes[6,7]. These findings suggest that there is no fundamental abnormality in the Na^+–K^+ ATPase enzyme in the disease, but there may be a defect in an ethacrynic acid-sensitive transport step. Therefore in order to obtain a better understanding of the cation transport defect one should measure the binding of labelled ethacrynic-acid rather than ouabain.

It is possible, however, that there is no basic abnormality in the mechanism of Na^+ transport in cystic fibrosis but in the action of agents regulating this process[8,9]. Membrane transport of this cation is controlled by hormones and cyclic AMP in a tissue specific manner[10]. Failure of a Na^+ transporting system in exocrine glands to respond to a specific hormone or cyclic AMP could explain why the defect is confined to these organs. Isolated model systems like fibroblasts and erythrocytes might not therefore show up this defect.

Yours faithfully

M. J. DUFFY

Biochemistry Department,
University of Dublin,
Trinity College,
Dublin 2

Drs Quissell and Pitot respond:

Due to the pathophysiology of cystic fibrosis, conclusions derived from data obtained from intact patients with the disease or from biopsy material obtained from CF patients must be carefully scrutinized. Several factors, such as anoxia, infection, malabsorption, liver and pulmonary involvement, and the nutritional and hormonal status of the patient complicate the interpretation of these data.

The Na^+ transport defect could be closely related to the genetic defect or the Na^+ transport defect could be secondary. The small salivary glands and the eccrine sweat glands are affected by the electrolyte defect in cystic fibrosis[11] but the submaxillary and parotid glands secrete normal levels of sodium[2,12].

The decrease in the ethacrynic-acid-sensitive efflux observed in cystic fibrosis erythrocytes[6] is difficult to interpret[13]. Lapey and Gardner[7] observed a normal sodium efflux in heterozygotes and in younger females with cystic fibrosis. The mechanism of action of ethacrynic acid on the overall membrane transport process is not known. In fact, the inhibitory process may involve one or several intracellular metabolic events rather than events on the membrane *per se*[14,15]. Ethacrynic acid does not seem to bind specifically to the membrane but to all cellular fractions[16]. Cystic fibrosis patients seem to have normal kidney function except for a lower metabolic clearance rate and a higher plasma aldosterone level which is probably due to the excessive loss of sodium in the sweat and a subsequent decrease in the intravascular volume[17].

If an alteration in the hormonal response in cystic fibrosis exocrine tissue is observed, the alteration could be intimately related to the primary defect in the disease but the alteration could be secondary to its pathophysiology. Careful evaluation will be required but the results should be very interesting.

obituary

Sir Charles Dodds

SIR CHARLES DODDS, Bt., biochemist and physician, who died on December 16, 1973, was at the time of his retirement in 1965 the senior professor in the University of London, having been elected at the age of 25 to the newly created Courtauld Professorship of Biochemistry at the Middlesex Hospital Medical School. Two years later, when the Courtauld Institute of Biochemistry was built he was its first Director, an appointment that he was to occupy with the highest distinction for 38 years. His originally tiny staff of three graduates expanded steadily so that due to his stimulating and inspiring leadership the Institute has acquired a fine reputation for both teaching and research.

Edward Charles Dodds was born on October 13, 1899, brought up in Darlington and moved with his parents to London, where he was educated at Harrow County School and the Middlesex Hospital Medical School, supporting himself by various scholarships and, later by tutorials. He was entirely a 'Middlesex man', who never seemed to wish to work elsewhere. Very early he showed his life-long interest in hormones, developing a method which proved useful for preparing insulin for the Hospital.

When they were both 25, he and F. Dickens wrote *Chemical and Physiological Properties of the Internal Secretions*. Dodds meanwhile was in charge of the Chemical Pathology and pioneered in this country the colorimetric methods of analysis which Folin had recently introduced in the United States. He was called in during the illness of King George V and, then aged 29, received the MVO. With George Beaumont he produced *Recent Advances in Medicine*

which ran to 14 editions. In more recent years, he was one of the first to introduce automation into clinical biochemical analysis in this country.

Dodds own research reached its highest point in the discovery of the highly potent artificial oestrogenic hormone, diethyl stilboestrol and its relatives. With Wilfrid Lawson, he explored the weak activity which they had detected in a range of simple non-steroidal compounds, until they found a highly active by-product arising in the demethylation of the simple phenolic ether anethole. They discovered the structure and synthesis of the compound, in work with Sir Robert Robinson, in 1938. Stilboestrol was even more active than the natural hormone, could be manufactured in quantity, and was effective when given orally. In addition to its value in gynaecology, it proved, following the lead of Charles Huggins, to be the first oral drug to be able to control a form of cancer—carcinoma of the prostate—even when the disease was disseminated.

The honours and decorations conferred on Dodds over the years occupy a whole column of Who's Who, but among these were his Knighthood in 1954 and Baronetcy 1964. He was elected FRSE. 1941; FRS 1942 (Vice-President 1957-9); FRCP 1933 (Harveian Librarian later) and President of the Royal College of Physicians in 1962—unique for a professor of biochemistry to be so honoured. He held honorary degrees from universities all over the world, was widely travelled and had lectured—though this did not come easily to him—in many countries. He succeeded Lord Horder as Chairman of the Scientific Committee of the Cancer Research Campaign; an excellent chairman, he was in constant demand in this capacity, serving on numerous Government and other scientific committees. His medical school owes to him the revolutionary reorganisation of the teaching of biochemistry, and of chemistry, which he insisted should be integrated subject; he built up a devoted staff of gifted teachers.

Though somewhat shy by nature, he was never aloof with his colleagues, always ready to discuss their problems, tempering his shrewd advice with a nice touch of humour. It delighted him when he became Master of the Society of Apothecaries in 1947–9, and nothing pleased him better than entertaining his many friends to good food and good wine, on which he was something of an authority.

His marriage in 1923 to Constance Elizabeth Jordan of Darlington was a happy one and he never seemed to his close friends quite to recover from her death in 1969. Their only son Ralph succeeds to the baronetcy.

Announcements

Corrigendum

In the article "Heavy ion transfer reactions in nuclear astrophysical processes" by T. W. Conlon (*Nature*, **247**, 268; 1974) the third paragraph from the end should read as follows. "A study of the α-transfer reaction $^{12}C(^{16}O,^{20}Ne)^{8}Be$ at energies in the region of the Coulomb barrier has been made possible by the development of a particle identification system based on position-sensitive counters mounted in the focal plane of a Buechner spectrograph. Preliminary results indicate that significant amounts of ^{20}Ne are produced with respect to ^{24}Mg, which results from the principal compound nucleus channel (Table 2)."

In the same article, the following corrections should have been made; para. 1, line 12 should read "corresponds to the transfer of an α particle, . . ."; para. 10, line 5, "available for later evolutionary . . ." and the last column in Table 1 should be "Q optimum (MeV) corresponding to (E_{min} to E_{max})".

APPOINTMENTS VACANT

KENNEDY INSTITUTE OF RHEUMATOLOGY

Have you seen our notice on page xv?

(1606)

PAPUA NEW GUINEA UNIVERSITY OF TECHNOLOGY

LECTURER IN CIVIL ENGINEERING

Applications are invited for the above-mentioned position in the Department of Civil Engineering. The work of the Department is organised into the sub-disciplines of Structures, Soils, Transport, Hydraulics, Public Health and Local Government Engineering.

Applicants must possess a good first degree and, preferably, a higher degree together with appropriate professional experience. The successful applicant in addition to lecturing duties will be required to undertake research and consultative work in one or more of the above-mentioned fields.

The academic establishment of the Department is 10 staff from the level of Technical Instructor to Professor. Laboratories are equipped to Australian University standards and each has supporting technical staff. Computer facilities are available in the form of two Nova 1200 series mini-computers for batch and time share processing and an ICL 2903 computer is to be ordered.

The Department is involved in consultancy, has a substantial practice in commercial testing and is becoming increasingly active in development projects to benefit small communities and small industries in this developing country.

Salaries within the range $A7,570 to $A10,205. In addition $A360 per annum is normally paid to a married male member of staff. Moderate rental housing is provided by the University. Superannuation may be provided.

Applications in duplicate should include particulars of age, nationality, marital status, family, if any, qualifications, experience, present post and the names and addresses of three referees from whom confidential enquiries may be made. They are required by July 1, 1974, and should be forwarded to The Registrar, The Papua New Guinea University of Technology, P.O. Box 793 LAE, P.N.G. An additional copy should be sent to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further particulars may be obtained. (1693)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF GENETICS

POST-DOCTORAL RESEARCH ASSOCIATE

Applications are invited for the position of Post-doctoral Research Associate. The successful applicant will be expected to take part in a study of the genetic fine-structure of the alcohol dehydrogenase locus in *Drosophila melanogaster*. This study, which aims to clarify the control of gene-action in eukaryotes, is supported by the Medical Research Council, and is carried out in collaboration with the Universities of Cambridge and Edinburgh. The appointment will be for three years, and the starting salary will be £1,923 (by £158). Preference will be given to candidates with a strong background in *Drosophila* genetics, or in studies of prokaryote fine-structure.

Applications, including a curriculum vitae and the names of three referees, should be sent to the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD, before Friday, May 17, 1974. (1712)

The Delft University of Technology

Chair in Biology

Applications are invited for a vacant chair in biology in the Department of Chemistry and Chemical Engineering. Appointee will be trusted with the following duties:

Teaching: The organization of an introductory course in biology for all students of the department and a course in computer simulation of biological systems.

Research: The initiation and direction of research devoted to one or both of the following themes:

(i) energy balances in biological systems

(ii) mixed cultures of two or more organisms.

Applicant should have experience in the formulation and experimental verification of quantitative models of biological systems. He should be willing to co-operate with biological and technological research groups in the department.

Applications, including biography, giving full details of qualification, experience, publications and names of two referees should be addressed to: Prof. L. L. van Reigen, c/o Bureau van de Afdeling der Scheikundige Technologie, 136 Julianalaan, Delft-2208, The Netherlands.

(1658)

NEW ZEALAND

Department of Scientific and Industrial Research

Applications are invited for the undermentioned vacancies:

SCIENTISTS

Botany Division of the Department of Scientific and Industrial Research, Lincoln, has vacancies for two Scientists.

(a) The Department is currently engaged in taxonomic work in all plant groups except fungi. Two volumes of the "Flora of New Zealand" have been published and other volumes are in preparation. A scientist is required to conduct taxonomic revisions of Dicotyledons in New Zealand Flora.

Qualifications: Honours degree or Ph.D.

(b) A botanist is required for the general services section to undertake taxonomic and ecological work on adventive flora in New Zealand. Knowledge of aquatic plants an advantage.

Qualifications: Honours degree in Science of Agriculture, Ph.D. or equivalent experience.

Salary for both positions: up to NZ $10,232 p.a. depending on qualifications and experience.

Passages: Fares for appointee and his wife and family, if married, will be paid.

Incidental expenses: Up to $120 for a single man and $800 for a married man can be claimed to cover the cost of taking personal effects to New Zealand.

Application forms and general information are available from the **High Commissioner for New Zealand, New Zealand House, Haymarket, London, SW1Y 4TQ,** *with whom applications will close on 13 June 1974.*

Please quote reference 2/151 when enquiring.

(1646)

Graduates and Technicians– Anti-Viral Research

G. D. Searle & Co. Ltd., is a research orientated ethical pharmaceutical organisation, based at High Wycombe in Buckinghamshire. The Research and Development Division is engaged on fundamental work in the fields of biochemistry, biophysics and immunology. Currently there is an expansion of our Anti-Viral Research programmes, creating vacancies for both scientists and technicians.

The scientific posts will be filled by graduates holding a Microbiology, Biochemistry, Zoology or Virology degree. Technicians should have at least an HNC in a Biological Science (or equivalent), coupled with laboratory experience in biochemical techniques. Attractive commencing salaries will be offered, and conditions of employment include 4 weeks' holiday, Pension Scheme and active Social Club. Assistance with relocation expenditure will be given in appropriate circumstances.

Initially please contact Mr H. W. Cooke, Personnel Manager, Research and Development Division, G. D. Searle & Co. Ltd., Lane End Road, High Wycombe or telephone High Wycombe 21124 extension 130 quoting reference ST/129.

TWO RESEARCH TECHNICIANS

Whitchurch Hospital, Cardiff

Applications are invited for the above two posts in the Addiction Unit Research Laboratory of the above hospital, to assist Dr M. Evans and Dr A. Badawy in investigating tryptophan metabolism in animals and man under conditions of drug dependence and treatment with other drugs. The laboratory is undertaking an interesting programme with both national and international activities, and the successful applicants will, therefore, be expected to show competent technical skill. They must be interested in biochemistry, and to preferably possess experience in enzymology, liver and brain biochemistry, chromatography, spectroscopic techniques or cell fractionation and tissue handling in general.

The posts are:

(a) JUNIOR TECHNICIAN/TECHNICIAN, on the N.H.S. scale of £708 to £2,292 per annum. Initial placing is according to age, qualifications and experience.

(b) TECHNICAL ASSISTANT for THREE YEARS ONLY, supported by a grant from the Medical Research Council carrying a salary of £1,263 rising in the third year to £1,395.

Application forms are obtainable from The Administrator and should be completed and returned to him within 14 days from the date of appearance of this advertisement.

(1708)

SOUTH-WEST THAMES REGIONAL HEALTH AUTHORITY IN CO-OPERATION WITH THE UNIVERSITY OF SURREY

offers training posts as BASIC GRADE BIOCHEMISTS with the opportunity to study for an M.Sc. in Clinical Biochemistry by means of a 2-year sandwich course commencing October 1, 1974. Applicants should have a degree in Biochemistry or Chemistry (or its equivalent).

During the parts of the course spent away from the University, students will work in a specified hospital laboratory within the Region. Probationary scale for new entrants to the service, £1,797 or £1,497, depending on class of degree, plus London Weighting Allowance where applicable rising by annual increments. Successful in-service applicants will retain their existing conditions of service. Students will be responsible for meeting the cost of University fees, currently £114 payable in three instalments during the two years, after which period they should be willing to serve a further year within the Region if posts are available.

Interviews are expected to be held in London in late May.

Further details and application forms obtainable from the Academic Registrar, University of Surrey, Guildford, Surrey GU2 5XH, to whom they should be returned by May 10, 1974. (1695)

SOUTH-EAST STAFFORDSHIRE HEALTH DISTRICT

THE GENERAL HOSPITAL

BIOCHEMIST (Basic Grade) required to work under the Principal Biochemist in well equipped laboratory at the above hospital. Attractive bed-sitting room available for female applicants.

Further information from the Principal Biochemist, The General Hospital, Burton-on-Trent.

Applications, stating experience and naming two referees, to Personnel Officer, Burton District Hospital Centre, Belvedere Road, Burton-on-Trent DE13 0RB. (1696)

NORTH-EAST LONDON POLYTECHNIC

Enquiries are invited for the post of:

SENIOR TECHNICIAN IN PHYSIOLOGY T4

in the Department of Biological Science based at our West Ham Precinct, Romford Road, Stratford E15 4LZ.

The Physiology Section of the Department comprises a wide range of laboratories and specialist rooms dealing with teaching to honours degree level and research in physiology. The successful candidate will be second in charge of the section and applicants must have appropriate qualifications and experience at a responsible level in the field of physiology.

Salary on a scale ranging from £1,749 to £2,031 per annum inclusive.

Further details and application forms from the Staffing Office, Ref. S/CF 129, North East London Polytechnic, West Ham Precinct, Romford Road, Stratford E15 4LZ. Telephone: 01-555 0811.

Please contact: Technicians Unit, Ext. 33.

Closing date May 17, 1974. (1694)

UNIVERSITY OF SOUTHAMPTON

FACULTY OF MEDICINE

LECTURESHIP IN HUMAN MORPHOLOGY

Applications are invited from biological graduates, preferably with a Ph.D., or from medical graduates for a teaching and research appointment in Human Morphology. Previous teaching experience is not essential; good research facilities are available in a variety of fields and experience in electron microscopy would be an advantage. Salary scale £1,929-£4,548 per annum (by 16 increments) subject to review. Initial salary will depend upon qualifications and experience. Enquiries should be directed to Professor D. Bulmer or Professor D. Mayor, Medical and Biological Sciences Building, Bassett Crescent East, Southampton, from whom further particulars may also be obtained.

Applications should be addressed to the Deputy Secretary (Ext. 2804), The University, Southampton SO9 4NH (7 copies from applicants resident in U.K. and one from others) not later than May 31, 1974. Ref. Na. (1637)

UNIVERSITY OF MALAYA

DEPARTMENT OF GEOGRAPHY

Applications are invited for the post of ASSOCIATE PROFESSOR in the Department of Geography. Candidates should have high academic qualifications and wide experience in teaching and research in the field of either Physical *or* Human Geography with special reference to South-East Asia. Subject to academic suitability and experience preference will be given to candidates who are competent in Bahasa Malaysia (Malay).

Salary scale (approximately sterling equivalent) £2,278 by £89 to £2,814/RP/£2,919 per annum. In addition the following allowances are payable: Variable Allowance £243 min., £649 max. per annum; Supplementary Housing Allowance £503 per annum and medical benefits.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

The closing date for the receipt of applications is **May 31, 1974.**

(1701)

AGRICULTURAL RESEARCH COUNCIL

POULTRY RESEARCH CENTRE

Applications are invited for a post within the SCIENTIFIC/HIGHER SCIENTIFIC OFFICER GRADES in the Ethology Section of the Poultry Research Centre, for work on reproductive behaviour. The project involves a certain amount of surgical work and the person appointed should be prepared to supervise technical staff.

Candidates should have a pass degree or H.N.C. in an appropriate biological subject, but specialisation in Ethology is not a necessity.

Salary within the scales £1,435 to £2,329 or £2,221 to £2,854 per annum, with placement according to qualifications and experience. A minimum of five years' post-qualifying experience is required for appointment in the higher grade. The post is superannuable with a non-pensionable allowance to offset contributions.

Application forms, which may be obtained from the Secretary, Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh EH9 3JS, should be completed and returned to him not later than May 21, 1974.

(1680)

WELSH NATIONAL SCHOOL OF MEDICINE

(UNIVERSITY OF WALES)

DEPARTMENT OF MEDICAL MICROBIOLOGY

Applications are invited for a

RESEARCH ASSISTANT

for Professor J. F. Watkins (who will be taking up his appointment on October 1, 1974). The appointee will work on the Cell Biology of Tumours and Tumour Viruses.

Previous experience not essential. Post suitable for a new graduate in biological sciences who would not wish to work for a higher degree.

Salary either on the scale £1,380 to £2,112 or on the technical scales depending on qualifications and experience.

Applications, with the names of two referees, to the Registrar, The Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN, within three weeks of the appearance of this advertisement. (1670)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

LONDON W1P 5PR

COURTAULD INSTITUTE OF BIOCHEMISTRY

A position as RESEARCH ASSISTANT in the Steroid Unit is vacant. Applicants should be at Doctoral level and should have a sound basis in Chemistry and Biochemistry.

Applications giving details of academic achievement and the names and addresses of two referees should reach the director of the Institute at the above address not later than Friday, May 17, 1974.

Salary, according to age, qualifications and experience, up to the maximum of £4,548 per annum plus £162 per annum London allowance plus superannuation under F.S.S.U. The appointment will be for a period of three years in the first instance. (1663)

JAMES COOK UNIVERSITY OF NORTH QUEENSLAND

LECTURER IN CIVIL ENGINEERING

Applicants should possess a higher degree and have teaching and research experience in the field of structural engineering; experience in wind engineering and an interest in low rise buildings and environmental aspects would be an advantage.

Salary range $A8,698 to $A11,982 per annum plus locality allowance of $A142 per annum for a married male, or $A71 for a single appointee. Conditions of appointment include superannuation, five weeks annual leave and an allowance for travelling and removal expenses.

Additional information and application forms may be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close on **May 24, 1974.** (1664)

RESEARCH AND DEVELOPMENT

New opportunities in Ulster

The R. & D. Division of Gallaher Limited, based in Belfast, is carrying out vital work in improving the health characteristics of smoking. Increasing the impetus of this work creates a number of new posts for able scientists, who will have excellent facilities for the work and opportunities for rapid personal development. The Laboratories work a 4½ day week.

GROUP LEADER—BIOLOGY GROUP

The Group of about fifteen people works broadly in Biochemistry, Toxicology and Cell Biology. It devises and develops biological systems for assessing the properties of new materials that may be smoked and for predicting their long-term effects. The Group Leader reports directly to the Research Manager. He must have a good Honours Degree and relevant biological research experience. He will also be involved in co-ordinating research projects in Europe. Therefore knowledge of French and/or German would be advantageous. We seek an exceptional scientist (age group 30–40) and offer him or her an exceptional opportunity.

BIOLOGICAL SCIENTISTS

Two new posts for graduates in their twenties are available in the above Biology Group, one in biochemistry, the other in tissue culture.

PHYSICISTS AND CHEMISTS

Several posts are now available for scientists interested in

The physical chemistry of combustion
Materials science of combustible materials (including tobacco)
Synthetic chemistry and
Analytical chemistry

Both long term and development problems are dealt with in inter-disciplinary groups. Applicants should be keen to apply scientific skill to commercial problems.

STATISTICIAN/BIOMETRICIAN

An Honours Graduate in mathematics, statistics and/or computing to develop techniques for the collation, analysis and interpretation of research data, particularly those from biological evaluations.

The Company offers first class conditions of service and initial salaries will be negotiable.

Applicants, male or female, may be graduates with suitable experience. For posts other than that of Group Leader—Biology Group, 1974 graduates may apply. Please write giving details of relevant academic and practical experience to :—

W. H. Forsythe, Manager, R. & D. Laboratories,
GALLAHER LIMITED, R. & D. Division,
Virginia House, Henry Street, Belfast BT15 1JE.

(1651)

UNIVERSITY OF TASMANIA

LECTURER IN AGRICULTURAL MICROBIOLOGY

Applications are invited for the above-mentioned appointment within the Faculty of Agricultural Science. The University would particularly welcome applications from people with training and experience in soil microbiology but the appointee will be expected to participate in teaching of general microbiology. He will be required to participate in supervision of honours and postgraduate students, and to undertake a personal research programme.

The salary scales are: Grade I $A10,575 to $469 by 3 to $11,982: Grade II $A8,698 to $470 to 1 to $469 by 2 to $10,106. Appointment will be offered within these grades according to qualifications and experience.

Further particulars and application forms from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close on **May 24, 1974.** (1673)

UNIVERSITY OF NEW SOUTH WALES

SCHOOL OF ELECTRICAL ENGINEERING

LECTURER

In field of communications. High academic qualifications in area of either high-speed digital systems or circuit applications of solid state devices. The School has well equipped research laboratories and particular research areas are optical communications, UHF and microwaves, communications systems, solid state devices and circuit applications, acoustics and biomedical engineering.

Salary: $A8,698 range $A11,982 per annum. Commencing salary according to qualifications and experience.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close June 28, 1974. (1691)

Wellcome

Senior Technician for Pharmaceutical Research

The Clinical Pharmacology Departments is looking for a Senior Technician to support an integrated clinical research group.

The work will initially involve drug assays primarily utilising gas chromatographic methods. An awareness of modern laboratory methodology and a good sense of organisation especially in the day-to-day running of an efficient laboratory will be necessary. Applicants should have a biochemical background and practical laboratory experience at H.N.C. or graduate level.

Our laboratories are situated in pleasant parkland surroundings within easy reach of Bromley and Beckenham and about 12 miles from Charing Cross.

Conditions of employment are attractive.

Please write quoting reference U.451 and giving brief details of qualifications and experience to the

Senior Personnel Officer,
THE WELLCOME RESEARCH LABORATORIES,
Langley Court, Beckenham, Kent BR3 3BS.

(1699)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF MEDICINE

Two posts: **SENIOR TECHNICIAN** and **TECHNICIAN/GRADUATE RESEARCH ASSISTANTS** for the Immunology Laboratory, Professorial Medical Unit. Responsibility will be in general laboratory immunology and will include service, research and teaching.

Applications, in writing, as soon as possible to Mr. R. S. Lloyd, Senior Chief Technician, Professorial Medical Unit, Royal South Hants Hospital, Fanshawe Street, Southampton SO9 4PE.
Tel. Southampton 34288, Ext. 336.

(1649)

OXFORD UNIVERSITY

THE DYSON PERRINS LABORATORY
(ORGANIC CHEMISTRY)

Applications from CHEMISTRY GRADUATES are invited for two S.R.C.-C.A.S.E. Studentships, tenable from next September, for research (leading to the degree of D.Phil.) on the synthesis of peptides of pharmacological interest, under the academic supervision of Dr. G. T. Young and in collaboration with industrial pharmaceutical research laboratories. The terms and conditions are similar to those for S.R.C. Research Studentships; undergraduates taking Finals this summer are eligible.

Apply immediately to Dr. G. T. Young, The Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY. (1697)

Biochemist

A leading British pharmaceutical Research Organisation has a vacancy for a Senior Biochemist to initiate and direct research projects in the areas of pharmacokinetics, drug metabolism, molecular pharmacology and enzymology in association with the design and development of new medicines.

Persons with appropriate experience are invited to apply in writing for further details to: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB, marking the envelope CONFIDENTIAL.

(1688)

North East London Polytechnic

Applications are invited for the post of:

Senior Technician T4 (3 posts)

based at our West Ham Precinct.

Psychology

This post in the Department of Psychology involves working with children and parents at the Department's Child Study Centre and responsibilities include security and maintenance of equipment in the Centre and care of a small animal house.
Candidates should have some relevant experience and preferably a knowledge of recording equipment.

Biochemistry

This position in the Department of Applied Biology involves responsibility for the satisfactory servicing of degree level practical classes in biochemistry including supervision and training of junior staff. Candidates should possess Final City and Guilds, HNC or equivalent. Experience of the use of advanced biochemical instrumentation will be considered an advantage.

Physiology

The physiology section of the Department of Biological Science comprises a wide range of laboratories and specialist rooms dealing with teaching to honours degree level and research in Physiology.
The successful candidate will be second in charge of the section and applicants must have appropriate qualifications to HNC or equivalent level and experience at a responsible level in one or more areas of Physiology

Salary on a scale ranging from £1,749 to £2,031 per annum inclusive.

The West Ham Precinct houses the Faculties of Science and Human Sciences and provides an extensive range of advanced facilities for teaching and research. Sports, canteen, library and other facilities are also available.

Further details and application forms from:
The Staffing Office, Ref: S/CF128
North East London Polytechnic,
West Ham Precinct,
Romford Road, Stratford E15 4LZ
Telephone: 01–555 0811

Please contact: Technicians Unit Ext. 33

Closing date 10th May, 1974. (1674)

OXFORD UNIVERSITY

Applications are invited from organic chemists for POSTDOCTORAL RESEARCH ASSISTANTSHIPS to work in the Dyson Perrins Laboratory with Drs. J. A. Barltrop and A. C. Day on the photochemistry of heterocyclic aromatic systems. Two such appointments are offered, each for a maximum period of 3 years, commencing not later than October 1, 1974. Previous photochemical experience is not essential. Applications will be accepted from those expecting to complete doctoral work this summer. The salary will be in the range £1,821-£2,223 plus F.S.S.U.

Applications, including curriculum vitae and the names of two referees, should reach the Administrator, The Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, as soon as possible, and not later than May 31, 1974. (1566)

UNIVERSITY OF GLASGOW

DEPARTMENT OF ZOOLOGY

Applications are invited for the post of RESEARCH ASSISTANT to work under Dr. P. Calow on triclad energetics. The appointment will be for not more than 3 years. Salary will be £1,475 (by £75) to £1,625 per annum.

Applications, with the names of two referees, should be sent, not later than June 30, 1974, to the Secretary, Zoology Department, The University, Glasgow G12 8QQ, from whom further particulars can be obtained. In reply please quote Ref. No. 3447M. (1686)

SCIENTIFIC SECRETARY

A part-time position of Scientific Secretary to the Eugenics Society will become available in August. The Society is concerned broadly with the biosocial aspects of human populations and the post would be suitable for a social scientist with an awareness of biological problems or a natural scientist with inter-disciplinary interests.

This new position will give the individual time for developing his own research interests, as well as being involved in the organisation of annual symposia and the Society's quarterly publication. Encouragement will be given to the person appointed to extend the scientific work of the Society. Support would also be given in any application for funds to transform the position into a full-time appointment at the Society's premises. Previous administrative experience would be an advantage. Salary according to age and qualifications within the range £1,500 to £2,500 for 3 days per week or the equivalent and superannuation cover will be arranged.

Further details may be obtained from the General Secretary, The Eugenics Society, 69 Eccleston Square, London SW1V 1PJ, to whom applications should be submitted not later than May 31. (1668)

THE WELSH NATIONAL SCHOOL OF MEDICINE

DEPARTMENT OF HAEMATOLOGY

TECHNICIAN OR SCIENTIFIC OFFICER

Technician or Scientific Officer required in the above Department to perform established tests of neutrophil function in leukaemia and allied disorders and to develop new techniques in this field.

Candidates should possess B.Sc. of H.N.C./A.I.M.L.T. in Haematology.

Salary according to qualifications but in the range £1,380 to £2,517.

Application forms available from the Registrar, The Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN, to whom they should be returned two weeks after the appearance of this advertisement.

(1709)

UNIVERSITY OF MALAYA

FACULTY OF SCIENCE

Applications are invited for the posts of LECTURERS/ASSISTANT LECTURERS in the Departments listed below. Subject to academic suitability and experience, preference will be given to candidates who are competent in Bahasa Malaysia (Malay). Candidates should have at least a good Honours degree with suitable teaching and research experience. For a Lectureship, a doctorate is normally required.

DEPARTMENT OF MATHEMATICS: Vacancies exist in the fields of Pure Mathematics, Applied Mathematics, and Statistics.

DEPARTMENT OF PHYSICS (two posts).

Salary scales (approximately sterling equivalents): Lecturer £1,524 to £2,441; Assistant Lecturer £1,330 to £1,460 per annum. In addition the following allowances are payable: Variable Allowance £243 min., £649 max. per annum; Supplementary Housing Allowance £503 per annum and medical benefits.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

The closing date for the receipt of applications is **May 31, 1974.** (1700)

UNIVERSITY OF OTTAWA

Applications are invited for a staff position at the associate or assistant professor level from individuals having a strong background in research in Organometallic Chemistry. Applicants with research interests in a related interdisciplinary field will also be considered. The applicant will be expected to participate in the teaching of General Chemistry as well as giving instruction at the advanced undergraduate and graduate levels. Ability to lecture in French, in addition to English, would be a distinct advantage. Salary will be up to $17,500 depending on the applicant's experience. The date of appointment is negotiable but September 1, 1974, is preferred.

Applicants should send a complete curriculum vitae and addresses of referees to: Professor H. H. Baer, Chairman, Department of Chemistry, University of Ottawa, Ottawa, Canada K1N 6N5. (1520)

Council for Scientific and Industrial Research South Africa

The Council for Scientific and Industrial Research consists of 15 national research laboratories and institutes. The CSIR undertakes and promotes scientific and industrial research into matters affecting the utilisation of the natural resources of the Republic; on the development of its industries and on the proper co-ordination and employment of scientific research to these ends.

The following vacancies are available in its NATIONAL CHEMICAL RESEARCH LABORATORY, PRETORIA.

BIOCHEMISTS

(ref 73/60/289) required for research on structure-function relationships of biologically active macromolecules. The programme envisaged includes the interaction of phospholipase A, cytotoxins, toxalbumins and other lectins with biological membranes. Excellent facilities and expertise in protein isolation, structure determination and physico-chemical characterisation are already available.

Posts are available on two levels, according to qualifications and experience:

Salary A: Between R8 300 and R10 700 (£5500 and £7150 approx) p.a.

Salary B: Between R5 000 and R7 950 (£3300 and £5300 approx) p.a.

Applicants with extensive experience in leading a research team will be considered for a position on the level of salary scale A.

CONDITIONS OF EMPLOYMENT: The many benefits include medical benefit scheme, assisted housing loan scheme, housing subsidy scheme, annual leave bonus, pension and group insurance scheme and annual leave up to 35 days. Successful candidates will receive assistance with travelling expenses and a contribution towards transportation of household effects. They will be required to make use of the Government immigration scheme and to serve the Council for two years in return for financial assistance.

Please apply to the following address:
The Office of the Scientific Counsellor,
Chichester House, 278 High Holborn,
London WC1V 7HE.
Telephone: 01-242 9641

Further details and application forms may also be obtained from this address.

(1661)

STATISTICIAN

FOR A MEDICAL RESEARCH COUNCIL UNIT IN EDINBURGH

A statistician, who will be senior amongst several on the scientific staff of the Unit, is required to work on the design and analysis of experiments in cell biology and genetic linkage, to advise on the biomathematical aspects of cell behaviour and to assist in studies on the epidemiology of human chromosome abnormalities.

Substantial in-house computing facilities, a high speed link to the Edinburgh Regional Computer Centre and programming support are available.

Applicants should have suitable academic qualifications and considerable experience in applied statistics, preferably in the biological sciences. The position offers excellent opportunities for collaborative work in a wide range of biological and medical projects, especially for someone whose interests include the biomedical field as well as statistical theory and technique. Commencing salary in the range £1,830 to £4,548 with possible promotion to Senior Grades.

To apply, or for further information, please contact the Director, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU. (1627)

We require a

RESEARCH ASSISTANT

to work in the

Chemotherapy and Biologics Department of our Central Research Laboratories

This is a new vacancy arising from expansion of our research activities. We are looking for someone to join the Antimicrobials project team. This team is involved in an increasing range of Bacteriological techniques including diagnostic work, tissue level studies etc. Candidates should have considerable experience in Bacteriological work and the ability to supervise junior staff.

This job would probably suit someone who has recently passed the final examination in Bacteriological techniques of the IMLT. Conditions of employment include non-contributory pension and death benefit schemes, canteen and social club facilities. Assisted travel is available from towns in the surrounding area. Our research Laboratories are situated on the Kent coast with easy access to London and the Continent.

Pfizer

If you are interested in this position please write for an application form to: G. Marshall, Personnel Officer, Central Research, Pfizer Limited, Sandwich, Kent.

(1669)

MINISTRY OF AGRICULTURE AND FISHERIES

SCIENTIST

WHATAWHATA HILL COUNTRY RESEARCH STATION, HAMILTON

NEW ZEALAND

Salary payable up to $11,986 depending on qualifications and experience.

Duties: Studies in the reproductive physiology of sheep and beef cattle with particular reference to the influence of nutritional and management factors affecting the fertility of hill country flocks and herds. Large numbers of genetically different sheep and cattle are available for study.

Qualifications desired: Masters or higher degree in agricultural or veterinary science, preferably with research experience in the general field of reproductive physiology.

Passages: Fares may be paid for appointee and if married for his wife and children to New Zealand.

Incidental Expenses: Up to NZ $120 for a single man and NZ $800 for a married man to cover the cost of taking personal effects to New Zealand.

Application forms and general information are available from the:
High Commissioner for New Zealand, New Zealand House, Haymarket, London, SW1Y 4TQ
with whom applications will close on 13 June 1974.

Please quote reference 2/14/59 when enquiring.

(1648)

UNIVERSITY OF BATH
SCHOOL OF BIOLOGICAL SCIENCES
POSTDOCTORAL RESEARCH FELLOW
RESEARCH ASSISTANT

Applications are invited for the above posts for work on the fish populations of the Severn Estuary supported by the Leverhulme Trust and the C.E.G.B., and based mainly on sampling from Power Station intakes.

The Postdoctoral Fellow will be expected to carry out a critical examination of sampling techniques and the analysis of seasonal changes in terms of environmental factors. In addition, studies will be carried out on the biology of the more important estuarine species and the successful candidate will be expected to initiate laboratory studies where these may be relevant to an interpretation of field data. Adequate training in statistical techniques and the computerised handling of data is desirable in addition to suitable research experience in the general field of freshwater or marine ecology.

The duties of the Research Assistant will include the collection of Power Station samples, the identification, examination and storage of specimens. Candidates should have an honours degree in zoology and preferably some experience of ecological and statistical techniques. A current driving licence is essential.

Both appointments are for a three-year period and the salary ranges are: Postdoctoral Fellow, £1,929 to £2,553; Research Assistant, £1,440 to £1,608.

Application forms, available from Registrar (S), The University, Bath BA2 7AY, quoting reference number 74/57, should be returned before May 22, 1974. (1666)

UNIVERSITY OF SOUTHAMPTON
FACULTY OF MEDICINE
PHARMACOLOGY—TEMPORARY LECTURESHIPS

Applications are requested from registered medical practitioners or from science graduates with appropriate qualifications for two Temporary Lectureships in Pharmacology on a full- or part-time basis for the academic year 1974/75. Experience in teaching medical students an advantage. Salary within range £3,588 to £5,091 (clinical) or £1,929 to £4,548 (non-clinical). Superannuation.

Further particulars may be obtained from the Deputy Secretary, The University, Southampton SO9 5NH, to whom applications (seven copies from U.K. applicants and one from others) should be sent not later than May 24, 1974. (1657)

THE EDINBURGH SCHOOL OF AGRICULTURE

POST-DOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a research assistantship in the Department of Agricultural Biochemistry for work on embryo development in higher plants. Candidates should be qualified in biochemistry or a related discipline.

The appointment, financed by the A.R.C. (salary scale £2,221 to £2,413, with F.S.S.U. benefits), is tenable for three years from October 1, 1974, and will be associated with a small group working on seed development and maturation.

Further details and application form from the Secretary, Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (1683)

UNIVERSITY OF TASMANIA

LECTURER IN AGRONOMY

Applications are invited for the above-mentioned appointment within the Faculty of Agricultural Science.

The salary scales are: Grade I $A10,575 to $469 by 3 to $11,982; Grade II $A8,698 to $470 by 1 to $469 by 2 to $10,106. Appointment will be offered within these grades according to qualifications and experience.

The particular field of interest of the Senior Lecturer in Agronomy (Dr. J. J. Yates) is the ecology of pastures. The faculty is particularly interested in applications from people with training and research experience in applied Genetics, including both plant and animal breeding. The appointee would also be required to lecture in some aspects of general Agronomy and it would be of great assistance if he could also assist in lectures on biometry in the fourth year compulsory unit, Agricultural Research and Extension Methods. The appointee would be expected to participate in the supervision of honours and postgraduate students and to undertake a personal research programme.

Further particulars and application forms obtainable from Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close on **May 24, 1974.** (1672)

MONASH UNIVERSITY

DEPARTMENT OF GENETICS

SENIOR TEACHING FELLOW

Applicants should normally have completed a M.Sc. or Ph.D. degree and will be responsible for the preparation and presentation of practical classes in Genetics in various years of the science course. The successful applicant will be expected to start late in 1974 or early in 1975. Facilities will be available for the successful applicant to undertake research in collaboration with the staff members of the Department.

Salary range: $A7,270 to $A8,698 per annum with superannuation based on an endowment assurance scheme, the employee and employer contributing 5 per cent and 10 per cent respectively.

Benefits: Travelling expenses for appointee and family, removal allowance, temporary housing for an initial period, repatriation after three years' service if desired.

Further general information and details of application procedure are available from the Academic Registrar, Monash University, Wellington Road, Clayton, Victoria 3168, Australia. Enquiries may be addressed to Professor B. W. Holloway, Chairman of the Department, from whom a detailed statement of current departmental research interests is available. Applicants should quote reference No. 30713.

Closing date: **May 31, 1974.**

The University reserves the right to make no appointment or to appoint by invitation. (1659)

THE DEPARTMENT OF CHEMISTRY, UNIVERSITY OF NEW BRUNSWICK, will make an appointment at the ASSISTANT PROFESSOR LEVEL, effective July 1, 1974, at the earliest. Duties will involve the teaching of general and physical chemistry courses in the undergraduate programme, and supervision of graduate students in M.Sc. and Ph.D. programmes. Research interests of the applicant should be compatible with the present interests of the Department and might include, for example, the fields of electrochemistry, nmr-esr spectroscopy, mechanisms of reactions in solution.—Applications, together with a research proposal, should be sent to: Chairman, Department of Chemistry, University of New Brunswick, Fredericton, N.B. E3B 5A3, Canada. (1655)

UNIVERSITY OF CALGARY, GRADUATE Teaching and Research Assistantships are available for students proceeding to the Ph.D. or M.Sc. degrees in all branches of Chemistry and Biochemistry. The Assistantships are valued from $4,100 to $5,000 per annum and carry remission of programme fees and travel allowance.

For further information write to: Department of Chemistry, Calgary, Alberta T2N 1N4, Canada. Please indicate field of interest. (1654)

NORTH-HOLLAND PUBLISHING COMPANY

(member of Associated Scientific Publishers, publisher of scientific journals and books).

has an immediate opening in AMSTERDAM for a full-time

editorial assistant physics

Description:

- preparation of manuscripts for printing
- correction of proofs
- language correction of contributions written by non-English speaking authors.
- supervision of free-lance workers.

Requirements:

- Degree, or equivalent in physics
- English mother tongue
- meticulous eye for detail.
- experience in proof reading preferred.

We offer responsible and variable work in a congenial atmosphere.

Handwritten applications, giving details of education and previous experience and an indication of salary expected, should be addressed to:

The Personnel Department,
Associated Scientific Publishers
P.O. Box 2400, Amsterdam
The Netherlands.

UWIST CARDIFF

University of Wales Institute of Science and Technology

Department of Applied Biology

RESEARCH ASSISTANTS (or RESEARCH STUDENTS)

required for the following appointments:

1. **For experimental study of effects of dust and sulphur dioxide on plants (3 years).**
2. **To study biological recovery of a polluted stream in South Wales (2 or 3 years).**

Applicants for this post should hold a car driving licence.

Salaries: Post 1: £1,318 to £1,499
Post 2: £1,499 to £1,657

Suitably qualified Research Assistants will be permitted to register for PhD with salary adjustments.

Also

3. **RESEARCH STUDENT to study the ecology of aquatic oligochaetes.**

Research Students will be given grants based on the SRC Awards scheme.

Further particulars and application forms (returnable as soon as possible) from Personnel Section, UWIST, Cardiff CF1 3NU. (1636)

NEW ZEALAND
Health Department

Applications are invited for the undermentioned vacancy:

SCIENTIST
National Health Institute
Wellington, New Zealand

A position is available for a Scientist with considerable experience in immunology and in particular the practical aspects of serological tests. The successful applicant will be responsible for the development of a wide range of serological techniques, production of antigens and antisera, research into and appraisal of new techniques, development of serological proficiency testing.

Qualifications desired: Ph.D. or M.Sc. with considerable experience in immunology or a medical graduate with postgraduate qualifications in microbiology.

Salary up to NZ$11,249 p.a. according to qualifications and experience.

Passages: Fares for appointee and his wife and family, if married, will be paid.

Incidental expenses: Up to $120 for a single man and $800 for a married man can be claimed to cover the cost of taking personal effects to New Zealand.

Application forms and general information are available from the **High Commissioner for New Zealand, New Zealand House, Haymarket, London SW1Y 4TQ,** *with whom applications will close on June 13 1974.*

Please quote reference 2/38/14 when enquiring.

(1647)

South Glamorgan Area Health Authority

Biochemists
(Basic, Probationary)

Vacancies exist in the Department of Chemical Pathology, University of Wales, Heath Park, Cardiff, for graduates in Chemistry or Biochemistry or one of the related biological sciences.

The department is closely linked with The Welsh National School of Medicine and carries out service work and research. It occupies new accommodation and has recently been equipped with a complete range of service and research equipment.

Holders of the posts will be expected to register as post-graduate students with The Welsh National School of Medicine and undertake research work with a view to obtaining the Ph.D degree. They will also be expected as part of their training to study for the Mastership in Clinical Biochemistry. Salaries and conditions of service will be those prescribed for Biochemists by the Whitley Council.

Further particulars and an appointment to visit the department may be obtained by writing to Professor C. N. Hales at the Department.

Application forms may be obtained from the Divisional Administrator, University Hospital of Wales, Heath Park, Cardiff.

(1653)

THE EDINBURGH SCHOOL OF AGRICULTURE

RESEARCH ASSISTANT

Applications are invited from Honours graduates in Microbiology or a related discipline for a research assistantship to work in the microbiology and biochemistry departments on silage deterioration studies financed by the A.R.C. The assistant will be expected to register for a higher degree. Salary £830 by £40 to £910, plus F.S.S.U. and fees.

Further particulars from the Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (1681)

UNIVERSITY OF ADELAIDE

Applications are invited for the following appointments:

LECTURER IN GEOGRAPHY (BIOGEOGRAPHY). Preference will be given to candidates interested in plant and animal geography, ecosystem structure and function, and ecology related to resource management. From January 1, 1975. (31.5.74)

LECTURER IN GEOGRAPHY. Preference will be given to applicants qualified to teach geomorphology and soil geography, with particular reference to Australia. From January 1, 1975. (31.5.74)

Salary scale: Lecturer $A8,698 by $470 (1) by $469 (6) to $11,982; with superannuation on the F.S.S.U. basis. Initial salary will be fixed within the scale in accordance with qualifications and experience.

Further particulars about these posts and the conditions of appointment and other information sought will be supplied on request to the Registrar of the University, or to the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications should be sent in duplicate and giving the information listed in the Statement that will be supplied, to the Registrar, the University of Adelaide, North Terrace, Adelaide, South Australia 5001. (1702)

UNIVERSITY OF MANCHESTER

DEPARTMENT OF MEDICAL BIOCHEMISTRY

Applications are invited for a POSTDOCTORAL RESEARCH ASSOCIATESHIP, financed by the British Heart Foundation, to work on "The Biosynthesis of Endothelial Basement Membrane Components of Blood Vessels". The appointment, from October 1, 1974, is tenable for two years. Salary range £2,118-£2,412 per annum plus F.S.S.U.

Applications (3 copies) giving the names of two referees should reach Professor D. S. Jackson, Department of Medical Biochemistry, University of Manchester Medical School, Stopford Building, Oxford Road, Manchester M13 9PT, before May 10, 1974. (1638)

UNIVERSITY OF HULL

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the post of Postdoctoral Research Assistant, funded by the Agricultural Research Council for a period of three years, for work on the effects of low oxygen concentrations on the regulation of lipid and carbohydrate metabolism of Azobacter, under the direction of Professor E. A. Dawes. Experience with chemostats and in enzymology would be an advantage.

Salary, according to experience, within the range £2,037-£2,223 (currently under review) with F.S.S.U. benefits.

Applications (4 copies) should be sent as soon as possible, to the Registrar, The University, Cottingham Road, Hull HU6 7RX, from whom further particulars may be obtained. (1642)

UNIVERSITY OF ESSEX

DEPARTMENT OF CHEMISTRY

Applications are invited for the post of

LECTURER

(£1,929 to £4,548; scale at present under review) in Inorganic Chemistry for appointment from October 1, 1974.

Applicants should have research interests in synthetic inorganic chemistry or in any other field of inorganic chemistry related to the overall research interests of the Department.

Applications (4 copies, quoting ref. PS/51/N) should reach the Registrar, University of Essex, Wivenhoe Park, Colchester CO4 3SQ, Essex, from whom further particulars are obtainable, by Friday, May 17, 1974. (1705)

UNIVERSITY OF NEW SOUTH WALES
WOLLONGONG UNIVERSITY COLLEGE

to become the

UNIVERSITY OF WOLLONGONG

January 1, 1975

LECTURER—DEPARTMENT OF PHYSICS

The appointment is for a solid state physicist either theoretical or experimental. In the latter case, preference will be given to applicants with a background in solid state spectroscopy. Experience in the use of digital computers will be useful in both cases. The appointee will be required to teach at undergraduate and postgraduate levels and to pursue an active research programme in his own particular field.

Commencing salary according to qualifications and experience, within the range $A8,698 to $A11,982.

Further information may be obtained direct from the College Bursar, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close May 15, 1974. (1677)

UNIVERSITY OF NOTTINGHAM
DEMONSTRATOR IN BOTANY

Demonstrator in Botany is required from October 1, 1974. The person appointed will be required to demonstrate in all aspects of Botany including Microbiology. The appointment is for three years and the person appointed will be required to register for a higher degree, preferably in the general field of plant cell and protoplast culture and the growth and selection of somatic hybrid cells. Salary on a scale rising to £1,569 per annum.

Application forms, obtainable from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham, to be returned not later than May 17. Reference Number -N. (1684)

UNIVERSITY COLLEGE OF NORTH WALES
BANGOR

DEPARTMENT OF ZOOLOGY

Applications are invited for the post of DEMONSTRATOR.

Applicants for this post should have either a Ph.D. or an honours degree in Zoology.

The initial appointment will be for one year commencing on October 1, 1974, with the possibility of a renewal for a further period of two years.

Salary will be £1,683 per annum plus F.S.S.U. benefits.

Applications (two copies), giving full details of age, qualifications and experience, together with the names and addresses of two referees, should be sent not later than May 31, 1974, to the Secretary and Registrar, University College of North Wales, from whom further particulars may be obtained. (1645)

UNIVERSITY OF SOUTHAMPTON
FACULTY OF MEDICINE

Applications are invited from registered medical practitioners or from science graduates with appropriate qualifications for two TEMPORARY LECTURESHIPS IN PHARMACOLOGY on a full- or part-time basis for the Academic Year 1974/75. Experience in teaching medical students an advantage. Salary within range of £3,588 to £5,091 (clinical) or £1,929 to £4,548 (non-clinical). Superannuation. Further particulars may be obtained from the Deputy Secretary, The University, Southampton SO9 5NH, to whom applications (7 copies from U.K. applicants and one from others) should be sent not later than May 24, 1974. Ref. Na. (1713)

ELECTRON MICROSCOPY TECHNICIAN

(Grade 3) required to assist generally in a fully equipped unit serving research and teaching in biological ultrastructure. The post offers opportunities in the development of techniques and instrumentation for applicants of appropriate interests and experience.

Salary in the range £1,825 to £2,095 per annum.

Applications in writing to Mr. R. Adams, Departmental Superintendent, Department of Botany, Imperial College, London SW7 2BB. (1711)

UNIVERSITY OF MANCHESTER
ASSISTANT KEEPER IN GEOLOGY
THE MANCHESTER MUSEUM

Applications invited for this post, vacant from October 1, from candidates with an interest in mineralogy and petrology. Salary range per annum (under review): £1,929-£3,048. F.S.S.U.

Further particulars and application forms (returnable by May 31) from the Registrar, The University, Manchester M13 9PL. (1644)

Council for Scientific and Industrial Research South Africa

The Council for Scientific and Industrial Research consists of 15 national research laboratories and institutes. The CSIR undertakes and promotes scientific and industrial research into matters affecting the utilisation of the natural resources of the Republic; on the development of its industries and on the proper co-ordination and employment of scientific research to these ends.

The following vacancy is available in the NATIONAL FOOD RESEARCH INSTITUTE, PRETORIA.

FOOD TECHNOLOGIST/ SCIENTIST (Ref. 73/89/268).

This vacancy is in the food technology division of the Institute and the work involves research into the processing and preservation of food products. The work involves basic and applied research as well as the handling of problems of the food industry.

QUALIFICATIONS: At least a four-year degree in Food Science and Technology, Chemistry or Chemical Engineering.

SALARY: According to qualifications and experience; between R3150 and R9300 p.a., plus a 15% pensionable allowance (£2415 and £7130 approx.).

CONDITIONS OF EMPLOYMENT: The many benefits include medical benefit scheme, assisted housing loan scheme, housing subsidy scheme, annual leave bonus, pension and group insurance scheme and annual leave of up to 35 days. Successful candidates will receive assistance with travelling expenses and a contribution towards transportation of household effects. They will be required to make use of the Government immigration scheme and to serve the Council for two years in return for financial assistance.

Please apply to the following address,

The Office of the Scientific Counsellor,
Chichester House, 278 High Holborn,
London WC1V 7HE.
Telephone: 01-242 9641.

Further details and application forms may also be obtained from this address. (1660)

UNIVERSITY OF SOUTHAMPTON
FACULTY OF MEDICINE

CHEMICAL PATHOLOGY

SENIOR CHIEF TECHNICIAN required to establish a rapidly developing metabolic and endocrine research laboratory. The successful applicant will be aged between 30-40 and will be responsible for development and running of multiuser analytical facilities. Will also be required to participate in research with the Professor and opportunities will be available for a research degree. Whitley Council conditions of service and salary will apply. Post available immediately. Further information obtainable from Professor K. G. M. M. Alberti, Tel. Southampton 777222 Ext. 3359.

Application forms and job description obtainable from the Personnel Officer, Southampton Health District, Tremona Road, Southampton SO1 6HU. Tel. Southampton 777222 Ext 3651. Closing date: May 24, 1974. (1635)

UNIVERSITY OF MANCHESTER
DEPARTMENT OF PHYSICS

POSTDOCTORAL RESEARCH

Applications invited for a two-year postdoctoral appointment (from October 1) to study molecular dynamics of condensed matter by laser light scattering. The group is currently studying molecular motion and properties of synthetic and biological macromolecules by techniques which include photon correlation spectroscopy. The post is suitable for candidates who have a background in Physics or Chemistry; previous experience in light scattering or macromolecular research an advantage, but not necessary. Salary range £1,929-£2,553 per annum.

Further information may be obtained from Dr T. A. King, Physics Department, The University, Manchester M13 9PL, to whom applications should be sent together with the names of two referees as soon as possible. (1641)

EAST BIRMINGHAM HEALTH DISTRICT

CYTOGENETICS

Cytogeneticist required (Salary Scale in accordance with Whitley Council scale for Top Grade Biochemists at present £5,190 to £5,919, to take charge of a new Regional Cytogenetics Laboratory within the new East Birmingham Hospital Laboratory now being built. Candidates should have a higher degree (Ph.D. or equivalent) and wide experience of cytogenetics.

The work of the department will include elucidation of chromosome abnormalities, antenatal diagnosis of chromosomal defects, postgraduate teaching and research. The director of the laboratory will also have duties in diagnostic cytogenetics in the Department of Human Genetics in the Infant Development Unit at the New Birmingham Maternity Hospital, adjoining the University. The successful candidate may be accorded honorary status in the University of Birmingham.

Candidates are invited to visit the laboratory by direct arrangement with the Regional Virus Laboratory (Tel: 021–772 4311 Ext 675).

Applications (one copy) must include the names of three referees, age and relevant experience, and must be received by the District Administrator, East Birmingham Health District, 45 Bordesley Green East, Birmingham B9 5ST.

Closing date for applications 17th May, 1974.

(1710)

BP

Product Development Technologist

Over the last few years, the research group of BP Proteins Limited, based at Grangemouth in Scotland, has developed a process for the production of high-protein dried yeast (TOPRINA) from petroleum by continuous fermentation and processing techniques.

Toprina is being marketed as an ingredient of compound animal feeding stuffs and, as part of our continuing development programme, the product range is being expanded to meet a variety of needs in the animal feeds market.

We now require a young graduate to fill a new appointment in the team involved in the Product Development programme. His work will include study of the properties of Toprina and the development of a range of products based on it.

The successful applicant must have a good degree in food technology or a related field. Some previous experience in research and development in the food or feeds industry would be highly desirable; indeed the post might suit a physical or natural scientist with such experience.

■ Salary is competitive and conditions of service are excellent. Please write, giving full details, quoting ref. U. 780, to: The Manager, Central Recruitment, The British Petroleum Company Limited, Britannic House, Moor Lane, London EC2Y 9BU.

(1629)

LIVERPOOL POLYTECHNIC

DEPARTMENT OF BIOLOGY

Applications are invited for the post of NERC RESEARCH ASSISTANT to work under the direction of Dr M. K. Hughes on the development of X-ray densitometry of tree-rings as an ecological tool.

Appointment is for 3 years from July 1, 1974. Salary: £1,251, £1,311, £1,357 per annum.

Details available from Staff Office, Dept., Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool L3 1RH. (1667)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS AL5 2JQ

PLANT PATHOLOGIST to work on fungal diseases of potato tubers, especially gangrene, during growth and storage. Minimum qualifications good honours degree.

Appointment in grade of Scientific Officer £1,435 to £2,329, or Higher Scientific Officer £2,221 to £2,854. Starting salary in accordance with qualifications and experience. At least two years' postgraduate experience is required for appointment as H.S.O. F.S.S.U. Further details on request.

Applications, naming two referees and quoting reference 2232, to the Secretary by May 31, 1974. (1687)

UNIVERSITY OF SYDNEY

ELECTRON MICROSCOPIST

Applications are invited for the position of Electron Microscopist in the Electron Microscope Unit. This Unit provides a service in Electron Microscopy both by way of research facilities and training courses to the various Departments. In addition to the advertised position, the Unit's staff includes a Director and two Assistant Electron Microscopists. Applicants for this vacancy should be experienced in the biological aspects of electron microscopy.

Salary within range: $A8,698 to $11,982 per annum or $A12,268 to $A14,308 per annum according to qualifications and experience.

Applications including curriculum vitae, list of publications and names of referees by **May 15, 1974,** to the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom further information available. (1662)

UNIVERSITY OF SYDNEY

P. N. RUSSELL CHAIR OF MECHANICAL ENGINEERING

Applications are invited for the P. N. Russell Chair of Mechanical Engineering which will become vacant on January 1, 1975, following the appointment of Professor D. W. George to the position of Vice-Chancellor at the University of Newcastle.

Salary will be at the rate of $A19,102 per annum.

A statement of conditions of appointment and information for candidates may be obtained from the Registrar, University of Sydney, N.S.W. 2006, Australia, with whom applications close on June 6, 1974. (1692)

UNIVERSITY OF CONNECTICUT

POST-DOCTORAL RESEARCH ASSISTANT

Protein Crystallography. $9,000 per year for up to 3 years.

Inquiries to: J. R. Knox, University of Connecticut, U-136 Storrs, Connecticut 06268, USA. (1685)

GRANTS & SCHOLARSHIPS

THE ROYAL SOCIETY

SCIENTIFIC PUBLICATIONS GRANT

Applications for grants from the first allotment of the Government Grant for Scientific Publications for the year 1974 should be made as soon as possible. No application can be considered which is received later than June 15, 1974. The grant is provided for the assistance of scientific publications in the United Kingdom, particularly but not exclusively those of scientific societies and institutions of a national character. A small part of the grant is available for the assistance of the libraries of scientific societies. Applications are receivable only from societies and institutions in the United Kingdom and individuals of British nationality.

Forms of application may be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG. (1698)

Trent Regional Health Authority

Regional Administrative Scientific Officer

(Salary Scale £5,409–£6,648 p.a.)

Applications are invited for the newly established post of Regional Administrative Scientific Officer. The successful applicant will be on the staff of the Regional Medical Officer and will be concerned with co-ordinating the development of the scientific services in the Trent Region, as recommended in Department of Health circulars and the Zuckerman Report.

Candidates, who should be qualified scientists with or without a medical qualification, should have a broadly based rather than a specialist background, and should have the ability to plan and organise.

Application forms and further details of the post are available from the Regional Administrator, Trent Regional Health Authority, Fulwood House, Old Fulwood Road, Sheffield S10 3TH, to whom completed applications, naming three referees, should be sent by May 17, 1974.

(1707)

ULSTER:
THE NEW UNIVERSITY

POSTDOCTORAL RESEARCH FELLOWSHIP IN CHEMISTRY

Organic or organometallic chemists are invited to apply for an S.R.C.-sponsored postdoctoral research fellowship to investigate orbital-symmetry-controlled reactions of hydrocarbon-transition metal complexes, in collaboration with Dr W. E. Watts.

The appointment is tenable for two years and is available immediately.

Salary (with F.S.S.U.): £1,929 by £129 to £2,058.

Further particulars may be obtained from the Registrar, The New University of Ulster, Coleraine, Northern Ireland (quoting Ref. 74/46) to whom applications, including the names and addresses of two referees, should be sent as soon as possible. (1650)

Please mention this Journal when answering advertisements

FELLOWSHIPS AND STUDENTSHIPS

APPLICATIONS OF LASERS IN SPECTROSCOPY

Applications are invited for a POSTDOCTORAL FELLOWSHIP in the applications of lasers to the study of high temperature inorganic species in gases.

Applicants are asked to send a curriculum vitae to Professor I. R. Beattie (Department of Chemistry, The University, Southampton SO9 5NH) from whom further details may be obtained. Salary on the range £1,929-£2,223 (under review) plus F.S.S.U. (1640)

University of Wales
University College of Swansea

The Welsh School of Pharmacy

RESEARCH STUDENTSHIP IN NEUROPHARMACOLOGY

Applications are invited from candidates with, or expecting to obtain, first or upper second class Honours degree in Pharmacy, Pharmacology, Physiology or a related discipline for a research studentship rising from a grant awarded to Dr. N. S. Doggett. The project, which is sponsored by an international drug company, concerns a study of the mechanism of action of tremorigenic compounds and may involve spending some time in the company's own laboratories in Switzerland.

The award is tenable for 3 years from September 1974 and the work will be suitable for submission for the degree of Ph.D. The value of the award will be £750 plus fees per annum, with appropriate additional allowances and extra remuneration for demonstrating duties to undergraduates.

Further details (quoting ref. N) and application forms (returnable by May 24, 1974) from the Academic Registrar, UWIST, Cardiff CF1 3NU. (1704)

UNIVERSITY OF BRISTOL
DEPARTMENT OF PHYSICS

RESEARCH STUDENTSHIP

sponsored by the National Physical Laboratory is available for the study of a new method of precision thermometry between 2 and 20K based on the dielectric properties of helium gas. The studentship is available for three years from October 1, 1974, at a salary which will be rather higher than the current Research Council studentship rate.

The work will be suitable for submission for the degree of Ph.D. Applicants should preferably hold a first- or upper second-class honours degree from a United Kingdom university, and must have an interest in and an aptitude for the use of precision measuring apparatus.

Applications should be sent to Dr. D. Gugan, Physics Department, Tyndall Avenue, Bristol BS8 1TL. (1689)

POSTDOCTORAL FELLOWSHIP IN PHOTOELECTRON SPECTROSCOPY

Applications are invited for an S.R.C. sponsored postdoctoral fellowship to investigate the electronic structure of molecular fragments and ions using beam photoelectron spectroscopy. Applicants should hold or expect to hold a Ph.D. in chemistry, physics or a related subject. Ability and genuine interest in small molecule chemistry are more important than previous direct experience. The post will be for one year in the first instance from a mutually agreed starting date. Salary will be on the range £1,929-£2,223 (under review) plus F.S.S.U.

Applications giving the names of two referees should be made as soon as possible to Professor N. Jonathan, Department of Chemistry, The University, Southampton SO9 5NH. (1639)

UNIVERSITY OF EXETER

DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for a NATURAL ENVIRONMENTAL RESEARCH COUNCIL STUDENTSHIP to investigate the interaction of soil animals and micro-organisms in the decomposition of leaf litter.

The value of the Studentship is £695 per annum plus fees (£540 per annum in the case of students living at home). Other allowances are payable in certain circumstances.

Candidates will be expected to obtain a good honours degree in Biological Sciences. A working knowledge of biochemistry will be useful.

Application forms and further particulars can be obtained from the Senior Assistant Registrar, quoting JMA/NERC/Biol. Sci., Northcote House, The Queen's Drive, Exeter EX4 4QJ. Closing date for applications: May 16, 1974. (1655)

HERIOT-WATT UNIVERSITY

Applications are invited for a

CASE studentship

in the Department of Chemistry. The successful applicant will work in collaboration with Organon Laboratories Ltd. on new amino steroids in a series already established as possessing interesting pharmacological and clinical properties. The project will involve working both in the University and the industrial laboratories.

The University is situated in a parkland campus just outside Edinburgh.

The student, who should have a good Honours degree, will register for the degree of Ph.D. Enquiries should be sent to Dr. M. M. Campbell, Department of Chemistry, Heriot-Watt University, Riccarton, Midlothian EH14 4AS. (1682)

UNIVERSITY OF NEWCASTLE UPON TYNE

ROBERT WOOD FELLOWSHIP

DEPARTMENT OF CHEMICAL ENGINEERING

Applications are invited for the Robert Wood Fellowship tenable in the Department of Chemical Engineering. Applicants must hold a B.Sc. degree (or be prospective B.Sc. graduates) of the University of Newcastle upon Tyne or Kings College in the University of Durham. Applicants for the Fellowship must intend to undertake research in Chemical Engineering topics. The Fellowship will be of the value of £695 per annum plus fees.

Further particulars and application forms may be obtained from the Registrar of the University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU. Completed application forms should be submitted to the Head of the Department of Chemical Engineering by June 30, 1974. (1643)

WESTFIELD COLLEGE
(UNIVERSITY OF LONDON)

N.E.R.C. RESEARCH STUDENTSHIP

for work on "Water and ion movement in live Sphagnum and peat" is available from October 1974. Peat covers about 2 per cent of the Earth's surface. The ecology of one of the major peat forming plants is to be studied.

The basic award is £695 a year and is under the N.E.R.C. regulations.

Applicants who have or hope to have a good honours degree in BIOLOGICAL, CHEMICAL or PHYSICAL SCIENCES will be considered.

Apply by May 29 to Dr. R. S. Clymo, Westfield College, Kidderpore Avenue, Hampstead, London NW3 7ST. (1671)

LANDSCAPE ARCHITECTURE. RESEARCH STUDENTSHIPS available for honours graduates in land use or natural science subjects.—Apply: Department of Landscape Architecture, The University, Sheffield S10 2TN. (1665)

UNIVERSITY OF EDINBURGH

RESEARCH STUDENTSHIPS IN SOCIAL ASPECTS OF SCIENCE

Studentships are available in the Science Studies Unit, Edinburgh University, for research on Appropriate Technology for Developing Countries; Differentiation in Modern Astronomy; and aspects of the Social History of British Science. Applicants must have (by July 1974) a good first degree in (preferably) science, technology, social sciences or history.

Contact: The Director, Science Studies Unit, University of Edinburgh, 34 Buccleuch Place, Edinburgh EH8 9JT. Please quote reference 5014. (1679)

Glaxo Travelling Fellowships for British Science Writers

FOUR AWARDS—EACH WORTH £500

Applications and nominations are invited for the 1974 Glaxo awards, which are open to all British science writers — specialists and general reporters, regional and national staffmen, and freelances in newspapers, periodicals radio and television. Applications may be made by either individual science writers or by editors on their behalf.

One £500 award is for science writing in a national magazine or newspaper during 1973.

One £500 award is for science writing in a regional magazine or newspaper during 1973.

One £500 award is for science writing in television or radio during 1973.

One £500 award is for science writing in a trade, technical or house magazine during 1973.

Closing date for entry: May 31, 1974.

Further details and application/nomination forms can be obtained from:

The Chairman, Association of British Science Writers, c/o New Scientist, 128 Long Acre, London WC2E 9QH.

(1703)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF GEOLOGY

RESEARCH STUDENTSHIPS

N.E.R.C. postgraduate Research Studentships tenable for three years from October 1974 are available for each of the following projects:

Organic and Trace Element Geochemistry of Jurassic Sediments from around Brora, Sutherland (Dr. M. Pearson and Dr. R. V. Dingle).

Pleistocene Sediments and Stratigraphy of Forties Field, Northern North Sea (Dr. R. V. Dingle).

Polymorphism and unmixing in alkali feldspars (Dr. I. Parsons).

For further particulars and application forms apply to Professor E. A. Tait, Department of Geology and Mineralogy, Marischal College, Aberdeen AB9 1AS. (1675)

UNIVERSITY OF BRISTOL

Long Ashton Research Station

ERNEST COOK POSTGRADUATE STUDENTSHIP

Applications are invited from holders of good honours degrees or equivalent qualifications (e.g. Grad.R.I.C. or M.I.Biol.) in Chemistry, Biology or Biochemistry, for a studentship offered by the Ernest Cook Trust of Fairford at a value of £700 per annum for three years, plus travelling expenses to study the antifungal activities of chemicals which might be effective in controlling Dutch Elm disease.

The work is a collaborative project between Dr. D. Woodcock and Mr. D. R. Clifford of Long Ashton Research Station, and Dr. J. N. Gibbs of the Forestry Commission, Alice Holt Lodge, Surrey. The successful applicant may register for a higher degree of the University of Bristol.

Further particulars and application form from the Secretary, Research Station, Long Ashton, Bristol BS18 9AF, to whom they should be returned by May 31, 1974. (1716)

LINCOLN UNIVERSITY COLLEGE OF AGRICULTURE

NEW ZEALAND

POST-DOCTORAL FELLOWSHIP

The Council of Lincoln College invites applications for a Post-doctoral Fellowship, tenable in any of the undermentioned Departments.

Agricultural Economics and Marketing; Agricultural Engineering; Agricultural Microbiology; Animal Science; Biochemistry; Entomology; Farm Management; Horticulture; Plant Science; Range Management; Soil Science; Veterinary Science; Wool Science.

The object of the award is to contribute to the research programme at Lincoln College. In addition to carrying out research, the successful applicant will be expected to participate in limited teaching activities without further emolument.

The Fellowship shall have a total value of NZ$7,600, part of which will be available for fares. The salary portion of the emolument is taxable in New Zealand unless a double tax agreement operates between New Zealand and the country of the successful applicant. Tenure will be for one year in the first instance, but may be extended at the discretion of the Council.

Conditions of appointment giving further details of this position at Lincoln College can be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College in Canterbury, New Zealand.

Applications close on May 31, 1974. (1678)

KENNEDY INSTITUTE OF RHEUMATOLOGY

RESEARCH FELLOWSHIP IN THE DIVISION OF BIOCHEMISTRY

Applications are invited from experienced biochemists with a background in subcellular fractionation to develop a new project to study control of matrix biosynthesis by connective tissue cells. Previous experience in connective tissue research not essential. Post supported by M.R.C. Salary according to age and experience up to £3,378 plus London Allowance plus F.S.S.U. superannuation.

Applications with curriculum vitae and names of three referees to Dr Helen Muir, Kennedy Institute of Rheumatology, Bute Gardens, London W6 7DW. (1605)

UNIVERSITY OF ESSEX

DEPARTMENT OF CHEMISTRY

Applications are invited for RESEARCH FELLOWSHIPS in each of the following fields:

1. Crossed molecular beam studies of elementary reactions (experience of scattering techniques would be of considerable advantage).
2. Chemi-ionization studies by electron spin resonance (experience in spectroscopy would be of value).
3. Shock tube studies of combustion-generated pollution.
4. Shock tube studies of initiation in fuel-air mixtures.

Candidates are expected to hold an appropriate qualification such as an Honours Degree in Chemistry or Physics and have three or more years research experience, although candidates with less experience may be considered.

Further details are available from Professor J. N. Bradley, Department of Chemistry, University of Essex, Wivenhoe Park, Colchester CO4 3SQ. Telephone 0206-44144, Ext. 2030. (1706)

UNIVERSITY OF ABERDEEN

POST-DOCTORAL RESEARCH FELLOWSHIP IN CHEMISTRY

Applications are invited for above post in collaboration with Dr. A. R. Forrester for work on the detection of reactive intermediates in organic reactions. Appointment is for one year from October 1, 1974, but may be continued for a second year. Post is covered by an S.R.C. grant and salary is in range £1,929 to £2,223.

Further particulars from the Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by May 25, 1974. (1714)

LECTURES AND COURSES

UNIVERSITY OF BRISTOL

H. H. WILLS PHYSICS LABORATORY

Applications are invited from candidates with, or expecting to graduate with, a good honours degree in Physics, Chemistry, Mechanical Engineering, Metallurgy, Ceramics or related subjects, for admission to a one year course of advanced study and research leading to the degree of

M.Sc. IN THE PHYSICS OF MATERIALS

The Course concerns the basic physical mechanical mechanisms underlying the mechanical properties of solids of all kinds and is particularly appropriate for new graduates who intend to enter laboratories involved in materials research.

Candidates who successfully complete the Course may be considered, if they wish, as qualified to proceed to further research work in the laboratory as candidates for the degree of Ph.D.

Enquiries should be addressed to Professor F. C. Frank, F.R.S., Director of the H. H. Wills Physics Laboratory, Tyndall Avenue, Bristol BS8 1TL. (1653)

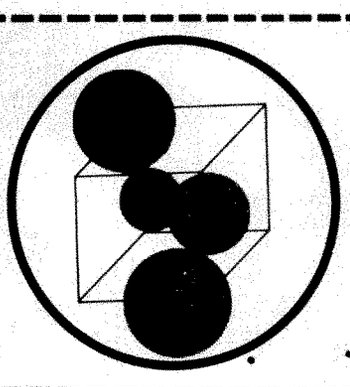
2-BEDROOM OR LARGER FURNISHED FLAT or house in London area wanted to let or sublet for Harvard professor. Roughly mid-June to late August/early September or slightly longer.—Write Box No. 1588, Nature, T. G. Scott & Son Ltd., 1 Clement's Inn, London WC2A 2ED. (1588)

Biological differentiation -a new journal.

Biological research has for too long suffered from restricted experimental attitudes and 'vertical' thinking.

Now Differentiation, an important new publication, provides the opportunity for interdisciplinary communication and increasing fertilization of ideas across the artificial boundaries created by overspecialization. This journal, published bi-monthly, offers up to date information and synthetic views of a problem underlining the whole biological phenomenon – differentiation.

The first five issues contained papers on:
Degree of differentiation in nonproliferating cells of mammary carcinoma. C. V. Wylie, P. K. Nakane and G. B. Pierce.
Polyribosome profiles and polyribosome-associated RNA of Friend leukaemia cells following DMSO-induced differentiation. H. D. Preisler, W. Scher and Charlotte Friend.
Studies on cytology and differentiation in Sciaridae. 5. Electron microscopic studies on the salivary glands of *Bradysia elegans* Morgante (Diptera, Sciaridae). A. B. Da Cunha, R. W. Reiss, C. Pavan, J. J. Biesele, J. S. Morgante and M. C. Garrido.
The principle of sequential dependence in cellular differentiation. P. A. Riley.
Time lapse filming of cellular interactions in organ culture. 2. The behaviour of malignant cells. E. J. Ambrose and Dorothy M. Easty.
Intercellular levels of cyclic nucleotides during cell enlargement and cell division in excised tobacco pith tissues. C. V. Lundeen, H. N. Wood and A. C. Braun.
Pattern formation in *Dictyostelium discoideum*: temporal and spatial distribution of prespore vacuoles. Ursula Muller and R. Hohl.
The enrichment of egg-type RNA in cleavage stage embryos of the sand dollar *Dendraster excentricus*. Shigeki Mizuno, H. R. Whiteley and A. H. Whiteley.
DNA synthesis and the production of antibodies by lymphoid tissues. G. Harris.
Neurite extension by mouse neuroblast: evidence for two modes of induction. P. Furmanski.



The journal aims to cover the following areas of study: embryonic Differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions *in vivo* and *in vitro*, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Contributions for publication are invited by The Editor.

Editor: Dimitri Viza. Faculté de Médecine Pitié-Salpétrière, Laboratoire d'Immunobiologie, 105 Boulevard de l'Hôpital, 75634 Paris Cédex 13, France.

Differentiation

Differentiation, published bi-monthly, provides the opportunity for interdisciplinary communication. This journal offers up to date information and synthetic views of a problem underlining the whole biological phenomenon – differentiation. It aims to cover the following areas of study: embryonic differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions in vivo and in vitro, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

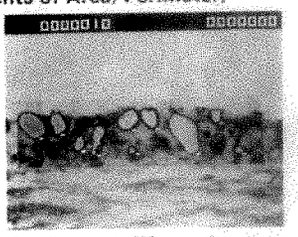
Recent papers include:
Degree of differentiation in non-proliferating cells of mammary carcinoma, C. V. Wylie, P. K. Nakane and G. B. Pierce. **DNA synthesis and the production of antibodies by lymphoid tissues,** G. Harris. **The principle of sequential dependence in cellular differentiation,** P. A. Riley. Edited by: Dimitri Viza. Faculté de Médecine Pitié Salpétriere, Paris.

Annual subscription £20 (£22.00 U.S.A. and Canada). Prices applicable only to orders started before 31st December, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

MARINE POLLUTION BULLETIN

Marine Pollution Bulletin is published monthly and sets out to cover all aspects of the fight for life of lakes, estuaries, seas and oceans. It includes news, comment, reviews and research reports not only on the threats of noxious substances to marine life but also on the management and productivity of the marine environment in general. It publishes accounts of new and proposed research programmes as well as the results of those in progress.

Recent research reports include:
Distribution of Caesium-137 in British Coastal Waters, D. F. Jefferies, A. Preston and A. K. Steele. **Export of Lead from Salt Marshes,** M. Banus, I. Valiela and J. M. Teal. **International Scope of Marine Pollution Damage,** D. P. Tihansky. **Effects of Red Mud on Marine Animals,** R. A. A. Blackman and K. N. Wilson. **Pollution Problem of the Golden Horn,** M. Karpuzcu.

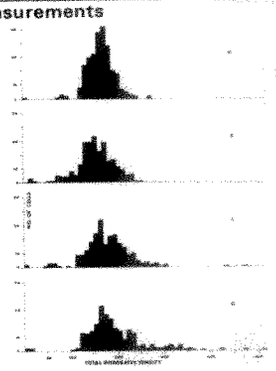


Annual Subscription £6.50 (£7.50 USA and Canada). Prices applicable only to orders starting before 31 December 1974. Payment may be made in any currency at the current exchange rate. Cheques should be made payable to Macmillan Journals Ltd., Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

Quantitative image analysis techniques replace subjective measurements in biological evaluation

The Quantimet 720 Image Analysing Computer now allows the Life Scientist to acquire accurate and objective data from a wide range of specimens. The Quantimet's accuracy, versatility and speed can be applied equally to microscopic, macroscopic or electron optic images for real progress in quantitative biology.

Simple Whole Field Measurements of Area, Perimeter, Projection and Number

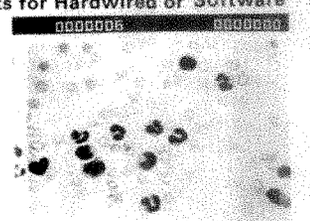


Simple Quantimet measurements on whole fields have been widely used in fields such as neurology, osteology and microbiology. Histological assessments can be readily quantitated as, for example, the assay of mucus secretion by the goblet cells of the respiratory tract.

The Quantimet 720 counting mucus containing goblet cells in colloidal iron/PAS stained sections.

High Speed Densitometric Measurements

The Quantimet 720 brings a new dimension in speed to true microdensitometric measurements, whilst virtually eliminating distributional error. Even using a light pen for manual selection of features gives total integrated density measurements, such as those below, at speeds of up to 1000 cells an hour. Simple densitometric measurements can be used to rapidly standardise histochemical techniques and can give quantitative objective descriptors even of very complex fields.



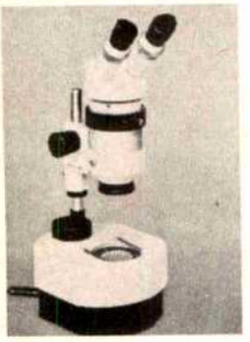
Histograms of DNA measurement in cervical smear samples: A normal, B normal, C suspicious, D malignant.

Feature Specific Measurements for Hardwired or Software Pattern Recognition

The Quantimet can allocate one or more temporary memories to each individual feature within an image. This allows "sizing" to be carried out using any of the standard parameters including integrated optical density, area or perimeter. Alternatively, different parameters can be combined for a single feature to give shape classification. The data of the temporary memories can also be made available to external computers thus allowing more versatile pattern recognition if this is required.

High Speed Analysis Gives Statistically Valid Data

The Quantimet 720 can measure one field of view in one-tenth (1/10) second; this allows rapid generation of statistically significant data. While automatic microscope stage movement and focussing can free an operator for other more rewarding tasks, the Quantimet monitor always shows exactly what is being measured. The data or image can also be fed out on-line to printers, desk top calculators or mini-computers for further analysis.



The nuclear form factor, area/perimeter², is used to select only mature neutrophils within the field of view while rejecting the immature forms.

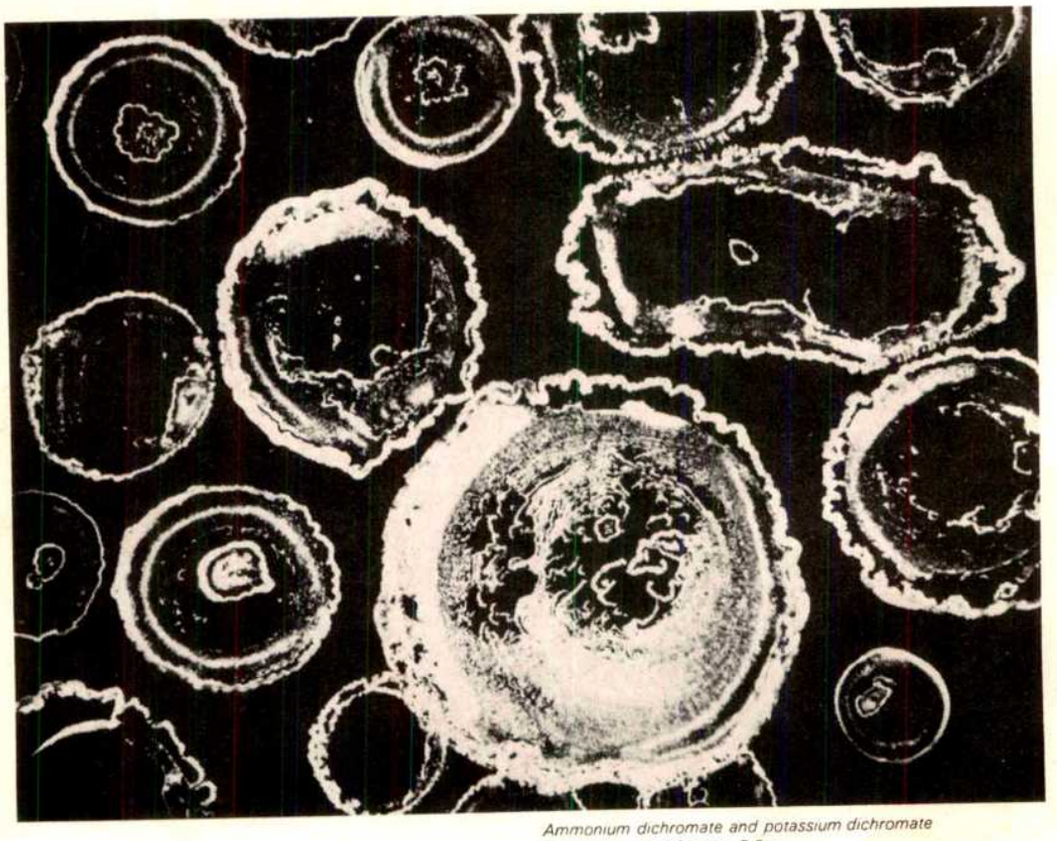
new

A choice of bright or dark field in the stereomicroscope



Wild M7 Zoom Stereomicroscope with transmitted-light stand (bright and dark field)

The new transmitted-light stand for Wild stereomicroscopes is designed for both bright and dark field. No adjustment is necessary - just move a lever and you change straight from one to the other. The fan-cooled 12 V/100 W halogen lamp gives uniform illumination, so the new stand is particularly suitable for photomicrography.

Cell.

It's not just another new journal.

The first issue of **Cell**, a new monthly journal of cell and viral biology from The MIT Press, was published in January, and already its astonishing growth, both in circulation and reputation, seems destined to make it one of the most important journals in its field. Edited by Benjamin Lewin, formerly the editor of *Nature New Biology*, **Cell** provides a wide-range journal publishing articles of general interest in molecular biology, cell biology, tumor virology, immunology, genetic development, and other related areas. Papers are refereed as rapidly as possible and those accepted are published within twelve weeks.

Cell also includes an extensive review section. In addition to those reviews with the traditional role of discussing a field in some depth, short reviews give conceptual accounts of recent advances in areas of cellular biology, for the benefit of researchers in other areas. Book reviews and discussions of meetings are also included.

The May issue of Cell will include the following articles and reviews:

Interaction of Regulator Proteins with Recognition Sequences of DNA: Benjamin Lewin

A Measurement of the Sequence Complexity of Polysomal Messenger RNA in Sea Urchin Embryos: Glenn A. Galau, Roy J. Britten, and Eric H. Davidson

Studies on Nascent RNA in Mouse Myeloma: Henry Berger, Jr., and Ru Chih C. Huang

Regulation of Intracellular Protein Breakdown in Stringent and Relaxed Strains of E. coli: Devorah Rafaeli-Eshkol and Avram Hershko

Mutations Affecting Adenine Phosphoribosyl Transferase Activity in Chinese Hamster Cells: Lawrence A. Chasin

Mutants of Cultured Chinese Hamster Cells Deficient in Adenine Phosphoribosyl Transferase: G. E. Jones and P. A. Sargent

Type C Viruses of Baboons: Isolation From Normal Cell Cultures: G. J. Todaro, C. J. Sherr, R. B. Benveniste, and M. M. Lieber

Vesicular Stomatitis Virus Envelope Glycoprotein Alterations Induced By Host Cell Transformations: Sue A. Moyer and Donald F. Summers

Inhibition of Transport Systems In Cultured Rat Hepatoma Cells By Colcemid and Ethanol: Peter G. W. Plagemann and John Erbe

Development of hCG-Sensitivity in The Testis of the Immature Rat: Wolfgang Engel and Joachim Frowein

The June issue of Cell will include the following articles, reviews, and book reviews:

The Gene Numbers Game: J. O. Bishop

Evidence for Genetic Recombination Between Endogenous and Exogenous Mouse RNA Type C Viruses: J. R. Stephenson, G. R. Anderson, S. R. Tronick, and S. A. Aaronson

Increased Protease Levels in Transformed Cells: A Casein Overlay Assay for the Detection of Plasminogen Activator Production: A. R. Goldberg

Changes in Adenylate Cyclase, Cyclic AMP, and Protein Kinase Levels in Chick Myoblasts, and Their Relationship to Differentiation: R. J. Zalin and W. Montague

Induction of a Deoxycytidineless State in Cultured Mammalian Cells by Bromodeoxyuridine: M. Meuth and H. Green

Expression of Thymidine Kinase Variants is a Function of the Replicative State of Cells: R. Adler and B. R. McAuslan

Book Reviews

Among the Protozoologists: S. H. Hutner
Cell Culture—the State of the Art: J. Bard
Ribonucleic Acids in Review: E. M. Scolnick

Subscription Prices
A year's subscription to **Cell** is $70 for individuals in the U.S., Canada, or Pan American Postal Union and $75 for individuals in other countries.
The subscription price for institutions is $100 in the U.S., Canada, or Pan American Postal Union and $105 for institutions in other countries.

Manuscripts and editorial correspondence should be addressed to the Editor or European Editor.

Cover picture
The green turtle marches into the Atlantic Ocean, to emerge 60 days later on Ascension Island, 2000 km away. How does it manage this precise navigation feat? Carr and Coleman (page 128) suggest an explanation based on the evolution of the Atlantic in the last 100 million years.

nature

Volume 249 May 10, 1974

UNTIL the end of 1973 *Nature* was set in England and printed in both England and the United States. The three-day working week imposed such severe constraints on us, however, that setting, printing and much of the despatch had to be removed to the United States; mailing from Richmond, Virginia, necessarily delayed delivery of *Nature* for Europe, Africa and much of Asia. We thank subscribers for bearing with us in this difficult time. This is the first issue for which we are again printing and despatching in England as well as the United States.

The paper for the English printing is Fletcher's 'Thinprint', of higher quality and much lighter than the coated papers we have used in the recent past. It has been a matter of concern to us that surface mail copies of *Nature* take so long to arrive, and yet that air mail subscriptions are too costly for many subscribers. The production of a lighter edition is the first step towards introducing cheaper air-mail subscription rates for 1975, of which details will soon be available.

Guide to authors

Nature accepts three types of communications:

● Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

● Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

● 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (*a*) is preferred to e^a if '*a*' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Ban the bomb—properly

AT long last there is a sign of life in the test ban business. For so long a sleeping partner among arms control proposals, some form of treaty to control underground nuclear weapons tests now looks like becoming a reality.

Underground weapons tests do little or no damage to people or property, but they do cause some offence on the international scene, particularly to countries such as India and Sweden who are exercising self-restraint in not going nuclear themselves. It must be surmised that the Soviet Union can see a diplomatic gain in negotiating now. Certainly Mr Nixon must see the advantage of being seen again as an international peace maker.

There are many issues which need discussion before the wheels of diplomacy turn too far. One such is the treaty that will be negotiated. There are three types:

- Thou shalt not (comprehensive).
- Thou shalt not be found out (technical).
- Thou shalt keep it in moderation (threshold).

Politicians would say that these three types represent increasing realism on the scientific aspects of monitoring. They also represent increasing cynicism and expedience of the negotiating parties.

There are many possible weapons so small that their testing could proceed unchecked except by espionage. A comprehensive treaty would rule such tests out; violation of the treaty would be a dangerous pursuit if only because the whole machinery of espionage could be brought to bear, with some justification, on exposing infringements. It may thus be politically unacceptable, not only as signing away nuclear rights but also as a treaty too easily abrogated.

At the other end of the spectrum, a threshold treaty would lay down a seismic magnitude above which a test may not be. This is a catastrophic procedure. For a start it ties matters of international security to a hopelessly complex scientific art. In 1968, the occasion of the last east-west scientific discussions on this matter, Russian and American delegates eventually had to agree that they always came up with a different number for the same event and an arbitrary correction had to be applied to prevent the discussions from breaking down altogether. When scientists sit down to write the language of any future threshold treaty they may again be seriously at odds—perhaps to the jeopardy of the treaty. Further, a threshold is a challenge to any nuclear country to improve its ability to decouple explosions from the geological surroundings, by firing in loosely compacted rocks or ultimately in large holes. With technological ingenuity explosions as large as 50 kilotons could be muffled to have a seismic magnitude of only 4.75, a widely discussed threshold value. Thus a threshold treaty would be gradually eroded by a determined nuclear power, and in time could become almost meaningless. And if the purpose of a treaty is to convince potential proliferating countries that the super-powers have a highly moral approach to nuclear weaponry, leaving open the door to tests of tens of kilotons will impress nobody. Finally, a threshold treaty will put back even further prospects for a comprehensive treaty.

If a comprehensive treaty is politically difficult, and a threshold treaty is meaningless, it is desirable to consider seriously a technical treaty. The onus is on a nuclear country not to be caught in activities it regards as vital. There is a continuing pressure on monitoring systems to improve, so the treaty is not so easily eroded. The treaty is not as vulnerable to violations as a comprehensive one would be, for the occasional detected test would be the subject of a discreet hint, not a diplomatic incident. One can hardly claim that a technical treaty is ideal—it too encourages an evasive approach by nuclear countries and it is not entirely inoffensive to non-nuclear countries but it represents a realistic goal for negotiation in the immediate future.

Negotiation on a treaty must not be impaled on the inspection issue. The concept of an annual ration of inspections must surely go; if inspections are needed they must be rare and subject to flexible arrangements.

Finally, explosions for peaceful purposes. In the United States these have made little headway, but the Soviet Union has a vigorous programme involving many explosions every year. Those within the United States who do not wish any treaty—and they include much of the atomic energy establishment—will point out that peaceful shots can be the guise for military tests (at least in the Soviet Union). If peaceful tests are seen as latter-day Trojan horses, then it is better that national programmes be stopped and resumed later under international auspices.

100 years ago

Col. Strange says :—

"I think it is an absolute necessity on the ground of my second postulate, in which I say that all science should be cultivated, even branches of Science which do not appear to promise immediate advantage. It is one of the most important parts of Science, and cannot be omitted without detriment to all the other parts. . . . . Investigations connected with almost the whole of our material economy are required. There is no question connected with sanitary improvement, with water supply, or sewage, or telegraphy, or the enormous number of the requirements of the army and navy, which would not derive advantage more or less from investigations of a physical nature such as would be conducted in a physical laboratory. I think that the whole of our naval and military and social economy is dependent upon investigations such as would be carried on in a physical laboratory."

INSTITUTE OF ... Date ...

Future of forestry in Britain

A government decision about the future of British forestry is expected shortly. John Gribbin reviews the possible development of forestry in Britain in the light of the recently published annual report of the Forestry Commission.

THE future organisation of forestry activities in Britain has been under consideration now for several years.

The Committee of Public Accounts of Session 1967–68 expressed concern over the substantial losses of the Forestry Commission and the poor prospects for the future. It was at that time that there was a call for a proper consideration of whether the commission's noncommercial activities produced sufficient social benefits to justify the heavy expenditure. So the feeling at government level of a need for a complete overhaul of the Forestry Commission can certainly be traced back six years, and the overall review of forestry in general stems from this careful look at the Forestry Commission.

A White Paper published in June 1972 outlined the direction in which the government saw forestry developing, and recognised the need for landscape improvement and maintaining the character of traditional hardwood areas. But in itself that review had little practical effect, although at about the same time smallwood planting grants were suspended and replaced by an interim grant scheme to bridge the gap until a new structure had been worked out.

By October 1973 Mr Anthony Stodart, the then Minister of State at the Ministry of Agriculture, Fisheries and Food (MAFF), was able to report to the Commons that a general framework for the future of forestry policy had been worked out, and details were then expected to be announced early in 1974. But the General Election and resulting change of government has delayed announcement of a detailed policy; in the House of Commons on April 11 Mr Stodart asked Mr Roland Boyle, the Secretary of State at MAFF who now has responsibility for forestry, whether a decision had now been reached, and was told that "consultations are still in progress". Pressed by a Member concerned that woodland owners had no idea what to do about the 1974–75 planting programme because the decision had not been taken, Mr Boyle replied "we have the matter very much in mind and hope to be able to announce a decision as soon as possible". Since then, the Forestry Commission *Annual Report and Accounts 1972–73* has been published (HMSO, 90p); together with previous government statements this makes it possible to foresee the likely development of forestry in Britain once the awaited government decision is announced.

One key change which has already been made is a reconstruction of the commission's accounts. From 1919 to 1972 the accounts have had to bear interest charges at the appropriate government lending rates, and these have averaged about 5% compounded over that period. Under the new structure the aim is to be a rate of return on funds of 3%, which is accepted as the maximum that forestry can be expected to earn in northern Europe on the best sites close to markets. That is an important proviso, for much of the commission's planting has been undertaken for strategic or social reasons, and cannot be expected to provide such a high return. "Where less profitable activities are undertaken for reasons of government policy", says the report, "the commission will be given . . . subsidies each year to bridge the gap between 3% and the expected rate of return".

This policy is not affected by Britain's entry into the European Economic Community (EEC), which has no common forestry policy. Regulations to implement two EEC directives concerning improvement of genetic and other standards of seeds, young plants and so on became effective on July 1, 1973, and the EEC Commission is considering a draft directive which, although chiefly devoted to improving the structure of agricultural holdings, has some implications for forestry. But otherwise the British government has essentially a free hand in forestry matters.

It must be remembered, of course, that only half of the total productive forest area in Britain is owned by the commission; but in practice the interests of private and state forestry are complementary and cooperative, rather than competitive. A major difference

Table 1 Land use by Forestry Commission at March 31, 1973 (Thousands of hectares*)

	Great Britain	England	Scotland	Wales
Total area	1,212.0	306.7	744.6	160.7
Forest Land: Total	882.1	261.7	481.9	138.5
Under plantations	768.3	239.5	399.5	129.3
To be planted	113.8	22.2	82.4	9.2
Other Land: Total	329.9	45.0	262.7	22.2
Nurseries	0.3	0.1	0.2	—
Agricultural and grazing	151.5	14.2	123.2	14.1
Forest Workers Holdings	5.1	1.1	2.9	1.1
Unplantable and miscellaneous	173.0	29.6	136.4	7.0

* 1 hectare = 2.471 acres

Table 2 Planting in the year ended March 31, 1973 (hectares)

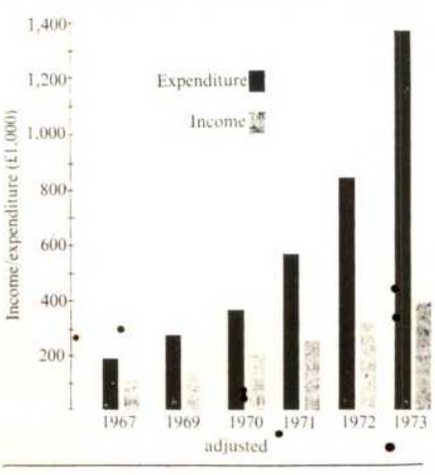
	Total	New planting	Restocking
Great Britain	23,158	19,378	3,780
Conifer	22,865	19,224	3,641
Broadleaved	293	154	139
England	3,154	1,735	1,419
Conifer	2,890	1,608	1,282
Broadleaved	264	127	137
Scotland	17,764	16,174	1,590
Conifer	17,739	16,151	1,588
Broadleaved	25	23	2
Wales	2,240	1,469	771
Conifer	2,236	1,465	771
Broadleaved	4	4	—

Conifers continue to dominate planting by the Forestry Commission, but that pattern is likely to be changed when details of the new government policy are announced.

Peeled woodwool billets stacked for air-seasoning in a clearing of 47-year-old Scots Pine at Bramshill Forest, Camberley.

is that private forests are concentrated on 'traditional' areas whereas the commission has afforested wide areas formerly in marginal agricultural use. The Forestry Committee of Great Britain, which represents private forestry in discussions with the government, generally sees eye to eye with the Forestry Commission, although it is in a better position to speak out against government proposals even to the extent of commissioning its own investigation of the accuracy of government studies relating to forestry. Of course, the two sectors of the forestry industry are in a competitive situation in the 'market place', but that market is so hungry for timber that both sectors are assured of selling their product.

Where the private sector differs from the Forestry Commission, however, is that small planters are in a much more vulnerable position when there is an air of uncertainty about the future direction the industry is expected to take. This is highlighted by the fact that the interim scheme for smallwood planting grants has now run its course, and that since the beginning of this year there has been nothing to replace it. A spokesman for the Forestry Committee said last week that small owners are already being affected, and that "some nurseries are finding it very tough" as a result.



This is a matter of more immediate urgency than the question of what should be planted in the 1974–75 season. For the private sector, the 1973–74 planting season is essentially over, and although there is a clear need for plans for the next season to be put in hand as soon as possible, there is probably less urgency about this at present than at any other time of the year. Of course, there can be little doubt that the detailed government plans will include a hardwood planting supplement—but it is up to the individual owner or planter to decide whether this is attractive enough for him to change his pattern of planting. All this takes time, and the present situation of uncertainty is clearly undesirable.

But the most important fact which must be taken into account when the government announces its new detailed plans is that in forestry terms Britain is very nearly saturated, with about 8% of the country covered by forest. Most of the figures in Table 1 are slightly down on last year; on March 31, 1972, for example the corresponding figures for forest land and total area were 876.2 and 1,215.0 thousand hectares, respectively. The total area of forest land acquired in the year ended March 31, 1973 was 6,000 hectares—more than 10,000 hectares less than in the previous year, and some 15,000 hectares less than in 1971–72. One reason for this is improvements in the sheep farming industry which make less land available for forestry; by and large, there is no longer any suitable land on the market.

In the light of this, and the removal of forestry's strategic role, the future emphasis is likely to be on forestry for amenity use. More hardwoods are likely to be planted than conifers, and existing forests will be promoted as recreational facilities. Indeed, the latter is already happening in a dramatic way.

The commission has also been involved in "plant a tree in '73" activities, including reclamation of 2 hectares of a derelict iron ore site in Cumberland, 6 hectares of coal tip at Kilsyth in Stirlingshire, and 12 hectares of derelict mining valley at Aberdare, Glamorgan.

It is perhaps ironic that these changes should be coming about at a time when world market conditions have caused a dramatic increase in softwood prices; demand for home grown sawlogs almost doubled in the last quarter of the year covered by the report and there is, according to the report, a "strong desire" among British wood-using industries to use the dependable home grown product wherever possible. But with Recreation Planning Officers appointed in most conservancies, a feasibility study underway investigating development of low cost tourist accommodation on commission land, and the general restructuring of the commission's activities the future of forestry in Britain is clearly going to be markedly different from its immediate past. It seems appropriate that the commission is making a move to a new headquarters, near Edinburgh, at this time: it will be installed there by the middle of 1975.

international news

More criticism of nuclear safeguards

Colin Norman, Washington

FOR the second time in less than a month, the Atomic Energy Commission has been hit hard with a critique of its safeguards against the theft of weapons-grade nuclear materials. The latest attack is particularly damaging to the AEC's public defence of its safeguards because it comes not from acknowledged critics of nuclear power but from an internal AEC study by four AEC consultants and one AEC employee.

Released last week by Senator Abraham Ribicoff, in spite of strenuous objections from the AEC, the study concludes that the commission's safeguards are "entirely inadequate" to prevent ingredients of nuclear weapons being stolen from the United States nuclear power programme.

A central criticism is that diversion of weapons-grade material from the power programme poses a greater threat to the public than the risk of a nuclear accident, yet "the relevant regulations are far less stringent". The study goes on to note that "It is our strong feeling that the point of view adopted, the amount of effort expended, and the level of safety achieved in keeping special nuclear material out of the hands of unauthorised people is entirely out of proportion to the danger to the public involved".

The AEC's reaction to these charges, outlined in a statement hastily distributed by its press office, is that there is not much danger of diversion of weapons-grade material at present because very little highly enriched uranium or plutonium is used to fuel the light water reactors which now form the basis of the nuclear power programme. But the commission added that it is "taking a hard look at the study to determine what additional measures should be taken to further strengthen the requirements to safeguard nuclear materials from theft".

The point is, however, that towards the end of the 1970s light water reactors will probably be operating on a plutonium cycle, which means that large quantities of weapons-grade nuclear material will be shipped around the country as reactor fuel. And if the fast breeder reactor lives up to the AEC's expectations, by the end of the century the amount of nuclear material flowing through the power programme could be sufficient to manufacture a quarter of a million bombs a year.

The study first finds fault with the system for accounting for nuclear materials in the fuel cycle. "The uncertainties in the accumulated material balances of the atomic energy operation of the country already make it impossible to say that an explosive mass has not been diverted, and if reliance is placed solely on material balance methods that statement will have to be expanded many, many-fold in the near future," the report says. Furthermore, the present system will not pick up the diversion of nuclear material quickly enough: "A skilled diverter [could] have constructed an explosive device before the system can reach a conclusion that diversion has taken place".

A major recommendation is that the federal government should establish a special security force to guard nuclear materials in transit and for "all protection functions which could require the use of force". The study also recommends that the commission should forge strong relationships with the Central Intelligence Agency and the Federal Bureau of Investigation to make sure that those agencies are devoting sufficient resources to the problem of nuclear theft.

The whole issue of nuclear safeguards is rapidly building into a potent weapon in the hands of nuclear critics in the United States, particularly in respect of plans to build a string of plutonium - producing fast breeder reactors around the country. In response to such criticisms, Representative Melvin Price, chairman of the powerful Joint Committee on Atomic Energy, announced last week that his committee has launched a special review of the mater and will be holding some hearings later this year.

Israel's nuclear plan

Nechemia Meyers, Rehovot

AFTER years of debating the construction of nuclear power stations, a proposition always vetoed by officials in the Finance Ministry because overseas experts assured them that power generated by conventional plants would be far less expensive in the foreseeable future, the Israeli Government has decided to put all its eggs in the nuclear basket.

Minister of Commerce and Industry Haim Bar-Lev has announced that from 1980 onwards, every power station built will be nuclear. The 1970s will see the construction of Israel's last new conventional power plant and her first nuclear one with a power-generating capacity of 600 MW, expected to be completed by 1982, when total national capacity is expected to be 4,200 MW.

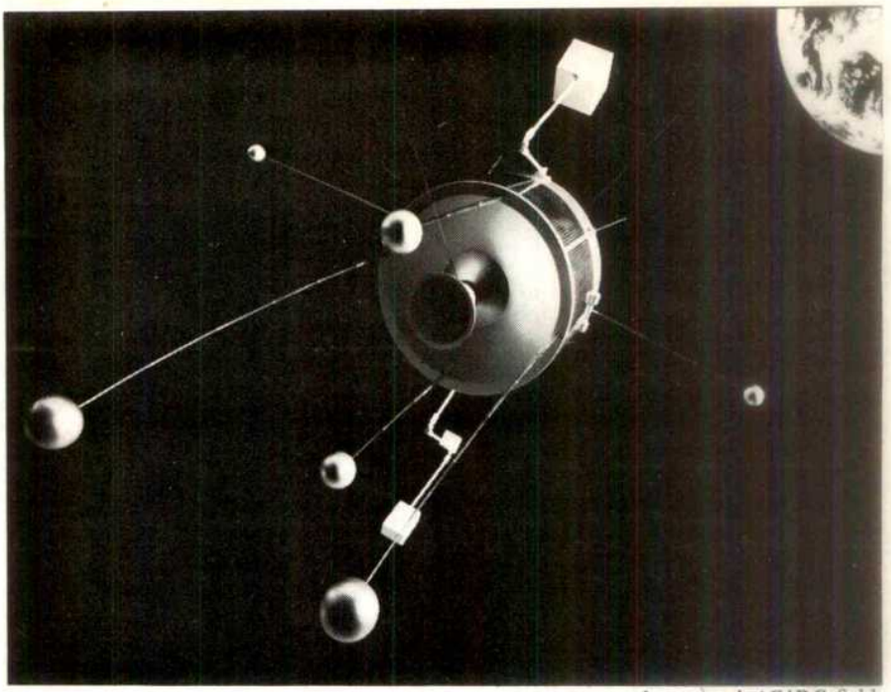
An international tender for construction of the nuclear power station will be issued later this year by the Israel Electric Corporation, which has been charged with construction of the plant; the Israel Atomic Energy Commission, which operates the country's two existing research reactors at Sorek and Dimona, will be responsible for ensuring stringent safety standards.

While some locally-made equipment will be used, reactors will almost certainly be bought from the United States, and a representative of General Electric, Asher Engler, has stated that his company is willing to provide the required enriched uranium for the first few years of operation but that future supplies of the strategically important material would depend on an agreement between the governments of Israel and the United States. Uranium could be extracted from phosphates from the Negev Desert, using locally developed methods, but it would still have to be enriched abroad.

Israeli environmentalists say that if Israel must have atomic power stations, they should be located in the furthest depths of the Negev, but the parched southern half of Israel lacks the large quantities of water required by nuclear power facilities for cooling purposes.

Whatever the validity of their arguments, the environmentalists have little chance of influencing government policy on this project. The first nuclear power station will soon be going up, probably near the new Mediterranean port town of Ashdod. If all goes well, there will be seven more by the turn of the century.

Soviet Scientists adopt new ploy



A UNIQUE international seminar will take place on July 1–5 in the Moscow apartment of Dr Alexander Voronel, a Soviet physicist who lost his job last year when he applied for a visa to emigrate to Israel. Organised by 19 Soviet Jewish scientists who have similarly been deprived of their jobs, and sponsored by an international board of advisors, the seminar is an attempt to keep the Soviet scientists in touch with developments in their own disciplines. It will undoubtedly pose something of a challenge to Soviet authorities.

Bearing the rather vague title of 'Collective phenomena and the applications of physics to other fields of science', the seminar has already met with considerable support in the international scientific community. A call for papers went out some seven weeks ago, and according to Dr Norman A. Chigier, professor of chemical engineering at the University of Sheffield, who is one of three international secretaries for the seminar, about 70 abstracts have so far been sent in.

Those who have submitted abstracts have been advised to apply for visas to enter the Soviet Union, and they have been told to make no secret of the fact that will be attending the seminar when they fill out their applications. Asked whether the Soviet authorities are expected to approve the visa applications, Chigier said that there is no way of knowing in advance, but that in the past they have been "unpredictable in their visa policies".

Chigier emphasised that the seminar should not be construed as "a confrontation with Soviet authorities". The Soviet Jewish scientists who are organising the event have been deprived of their right to travel abroad to attend scientific meetings and many have also been denied requests to attend meetings within the Soviet Union. According to Dr Edward Stern, professor of physics at the University of Washington, Seattle, who is also an international secretary for the seminar, the meeting has been organised to help Soviet Jewish scientists "break out of this scientific isolation which smothers and destroys scientific creativity." Chigier added that the event is "a gesture of solidarity".

All formal scientific meetings in the Soviet Union must be approved and organised by the USSR Academy of Sciences, but by labelling this event a seminar and holding it in a private apartment the organisers hope to circumvent the official regulations governing international scientific conferences.

GEOS: launching in 1976 to measure magnetospheric plasma and AC/DC fields.

The French in space

from the staff of La Recherche

THE relaunching of a European space policy, which should be confirmed by the creation as of mid-June of the European Space Agency (ESA), will give a second wind to French space efforts. The third space power, France has in fact launched but twelve satellites—only nine successfully—in twelve years of rather irregular activity. The enthusiasm of the first years was followed by an eclipse of three years (1965-67), then a stabilisation.

For the first time this year the French space budget will reach a thousand million francs. This is to be accompanied by a reorientation of the activities of CNES (the National Centre for Space Studies) towards greater European co-operation. The national programme becomes a support activity but bilateral operations, principally with the United States and the Soviet Union, will continue in order to permit participation in original programmes which are beyond French means. Thus scientific experiments will be put aboard the American probes OSO-1, Pioneer–Venus, IMP-L and Mariner–Jupiter–Saturne, while the Soviet Union will launch two small French technological satellites (Sret) and prepare the experiment EOS (release of a French balloon in the atmosphere of Venus). Co-operation with Germany will come about within a year with the launching of two telecommunications satellites (Symphony).

Thus France is putting its efforts into activities within the European community, in order especially to keep ahead of Germany. While continuing to participate in the programmes of scientific satellites and applications devised by ESRO (European Space Research Organisation), such as the inhabited orbital laboratory Spacelab, Paris is in fact concentrating more on the heavy launcher Ariane. True to its policy of European independence, France considers that the independent exploitation of future European telecommunication satellites depends on having a launcher available, and has therefore decided to finance nearly 65% of the development cost of this launcher (2,472 million francs with 20% for contingencies) and to take control of the project. Technical and financial management has been assigned to CNES, under the control of ESA.

This is clearly an ambitious project and in taking over his post at the beginning of the year the new president of CNES, Mr Maurice Levy, recognised that it is "both a heavy responsibility and a technical challenge to which every resource will have to be devoted".

A three-stage launcher of 200 tons capable of placing 750 kg into fixed orbit. "Ariane" will be the largest rocket constructed in Europe and the first to use cryogenic ergols (liquid hydrogen and oxygen), which assure high performance but of which the Europeans do not yet have much experience.

The success of this project requires a combination of efficient management, thorough pilot studies and the maintenance in active service of teams and resources for French launchings. The launching range in Guiana will have an important part to play; up to 1977 it will have only six Diamant BP4 rockets to launch to put into orbit the

future French satellites Starlette (October 1974), Castor and Pollux (January 1975), D2B (mid-1975), D2B-Gamma (mid-1976) and Dialogue (end of 1977).

Thus the career of Diamant BP4 is practically finished and if a new 'dead period' is to be avoided before the arrival of the launcher Ariane, scheduled for 1980, a replacement must be found immediately.

Several projects are envisaged by CNES, for example a "Z launcher" which would use the two upper stages of Ariane and which could place 575 kg into low terrestrial orbit (400 km); the capability of Diamant BP4 is only 170 kg. But in fact the choice of the future national light launcher depends in part on an eventual programme of French military satellites and until now it has been uncertain whether this would make an entrance before 1980.

The electronic newspaper in view?

Ian Ridpath

WITH newsprint scarcities the world over, this could be an opportune time to turn into reality the science-fiction dream of an electronic newspaper that flashes information into each home at the touch of a button. And, as a result of a test programme currently under way, that is exactly what could be happening in the United Kingdom within two years.

These exciting plans stem from the realisation that almost every home has a data terminal for receiving visual transmissions—a television set. The broadcasting companies have decided to use this exciting facility to provide an extra service.

By coding the electronic newspaper transmissions on normal television broadcasts, and incorporating a decoder in domestic television receivers, the system can be run without using any extra band space on the already crowded airwaves. According to equipment manufacturers, the extra circuits needed in a new receiver would cost a thoroughly reasonable £20, although adding a converter to an existing set might cost between £50 and £100.

The trick in sending out the data is to use two television scan lines that are normally redundant. These are lines 17 and 18, which remain out of sight at the top of the picture. Each of these lines now contains pulsed information for one 'row' of the electronic newspaper's 'page'. A page is a screenful of data; there are 24 rows on each page and each row has 40 characters. Prototype receivers to pick up this year's forthcoming test transmissions are now being produced by industry.

A newspaper of around 60 pages will be produced at first, although up to 99 pages are possible. The complete set of pages will take less than 30 seconds to build up inside the receiver's store and continual changes will be added, second by second, as the news comes in. An editorial team at the transmitting centre will feed news into a computer, which will encode it for transmission.

This service would be particularly valuable at times such as elections, but for normal use the electronic newspaper is likely to carry sports results, stock market prices, weather reports, and news bulletins. Simple line illustrations will be possible on the system, and the independent channels may well include advertising.

It is difficult to foresee how sales of printed newspapers will be affected by electronic data transmission to the home. Existing radio and television coverage has not destroyed the newspaper market and the summarised information of the electronic newspaper may even increase demand for longer printed reports. But the potential of the system may have more subtle long term effects and there is clearly considerable room for lobbying by interested parties.

At home, the viewer with a suitable receiver will be able to watch television programmes normally until he decides on a change. His set will have a push-button console on which he can punch up the page number of the electronic newspaper he wants. Page 1 of the paper will probably be given over to an index of the full contents. The pages of the paper, which have been stored in the receiver, will then be displayed with a header line showing the time to the nearest second, thus increasing the effect of 'instant information'.

Both the BBC and the IBA (Independent Broadcasting Authority) independently developed their own electronic newspaper transimssion systems, which they have been experimenting with since last year. But they have just agreed on an improved common system, engineering details of which are about to be published.

This standard system, which the prototype sets are designed to receive, enables viewers to pick up transmissions on all channels. Test transmissions to prove the new system's potential are to begin in the autumn, although it is not clear whether members of the public will be able to join in the fun of watching the editorial teams iron out their snags.

What is certain is that, after the trial period, a decision will be needed by the broadcasting companies, the receiver manufacturers and the Ministry of Posts and Telecommunications to begin full scale public services. It will be a historic decision, for this will be the world's first commercially available system of its kind.

Drug research in the UK

Peter Newmark

A SERIOUS failing of the drug companies was recently emphasised by Dr J. W. Black in his inaugural lecture as professor of pharmacology at University College, London. Returning to academic life after 15 distinguished years with ICI and Smith, Kline and French, he pointed out that industry was primarily interested in research and development of those drugs that might cure the most common diseases. This makes economic sense to the companies but means that those who suffer from rarer complaints are being cheated of their chance of a cure. The victims of, for example, multiple sclerosis and muscular dystrophy are included in this deprived category.

Professor Black offers a two-pronged approach to the alleviation of this imbalance. First, he is instigating a novel degree course aimed at overcoming the deficiences and hence the paucity of academic, pharmacological research. Second, he suggests a National Drug Research Centre to concentrate on those areas neglected by industry. Where the vast funds for this would come from is anybody's guess. It is a sobering thought that of many thousand folic acid antagonists synthesised and investigated to date, only one, methotrexate, offers much to the treatment of cancer. And for those with the rarer disease it is only an inapt comfort that can be sought in the vast array of money-making antidepressants and tranquillisers that pour from the laboratories of the drug companies.

Latest figures compiled by the Office of Health conomics in London show that expenditure on medical research in the United Kingdom topped the £100 million mark for the first time in the financial year 1972–73. This represented an increase of about one-fifth over the previous year, though must be considerably less in real spending terms. Of the total expenditure, the government contributed 61%, charities and trusts a notable 13% and the pharmaceutical industry a dwindling 26%.

These statistics give no indication of which areas of medical research benefited most from the funds, let alone what returns were received by the investors, be they the public or shareholders. One thing that is certain is that most pharmaceutical research was done by the relevant industry. This is probably as it should be. To what extent it is in the public interest is less certain and the present government is not averse to nationalising parts of the industry if it feels that this is the best action for the nation.

Business report: profit and tax

Roger Woodham

THE more one enquires precisely how much meaning can be attached to a company's 'profit' as presented in its annual report, the more the answer seems to be 'relatively little'. This was highlighted in a paper by Parker and Gibbs presented recently to the Institute of Actuaries in London.

The drift of their paper is that companies of most kinds, except those in service industries, would come up with considerably smaller profits if inflation were not taken into account in some way or another. For example, it is conventional accounting practice not to take into account inflation when amounts are set aside for depreciation of plant and machinery, so the profit seems to be that much larger and has to be dipped into to replace that plant or machinery at the inflated prices. Likewise, "profits are overstated by the inclusion of profits on stock which arise solely from a general increase in price levels".

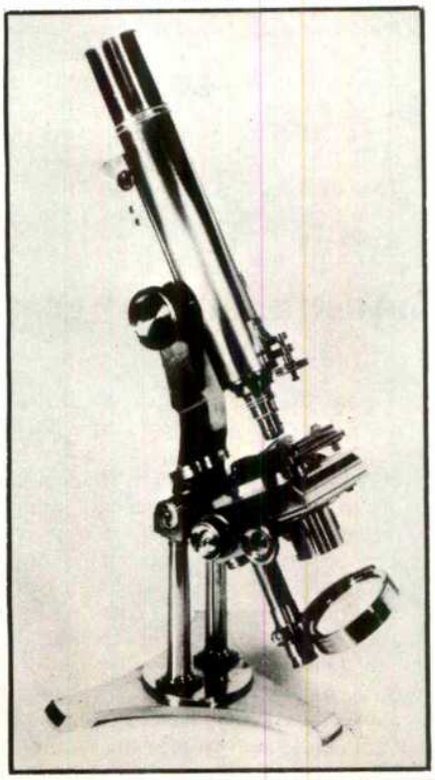
Parker and Gibbs produce some interesting findings using the CPP (current purchasing power) method of accounting. Here allowance is made for inflation by using a single index, for example the retail price index, to set up the company's accounts in terms of end-of-accounting-year pounds. This is a rather crude method, however, for it does not take into account the rise in price of a particular commodity, which may be much more than the increase in a broadly based index.

Parker and Gibbs show that the chemicals sector would have earnings 15% down on average, oil 25% down, and general engineering and eletricals 50% down according to CPP accounting. More specifically, ICI's earnings for 1972 would have been 45% less and BP's 65% less. In 1973 BP earnt £310 million (compared with £70 million in 1972) but on huge total sales of £4,500 million. Only detailed analysis will reveal what inflation accounting would have made of that.

As J. M. Keynes is thought to have said: "It is better to vaguely right than precisely wrong".

●If the United States Internal Revenue Service (IRS) gets its way about the taxing of multinational companies based in that country, some companies may find it financially worthwhile to shift more of their research and development effort abroad.

Even the IRS admits that the situation is complex, but basically what happens now is that tax calculations for multinationals in the United States do not take into account the fact that some earnings outside the United States are generated by money spent in the United States, for example on research and development.



A company can obtain 'foreign tax credits' (which can be offset against United States tax) in respect of taxes paid to foreign governments. The IRS wants a proportion of 'home' expenditure on research and development to be shifted on paper to foreign operations, which means less foreign income and less foreign tax credits in the United States. The IRS has a complex way of calculating these credits and, in the final analysis, the pre-tax profits of multinationals based in the United States would be reduced—some say by 3%, typically. Certain companies, notably in the pharmaceutical industry, stand to lose more because their research and development programmes are particularly centralised; they would face a great pressure to do more research abroad.

The matter is still under consideration at the IRS and a decision is not expected for some months. The interested companies are, however, putting up a formidable legal fight.

Microscopic appeal

David Davies

A microscope as old as the society

THE Royal Microscopical Society has launched an appeal for £50,000 to expand its operations. In particular, it plans to increase its educational activities and publish its *Journal of Microscopy* more frequently. The appeal was launched by retiring President, Professor A. G. E. Pearse on April 30.

The society has had a chequered career. It was founded in 1839 when the microscope was as much as anything the preserve of amateurs but when exciting times were just around the corner for microscopists. Leeuwenhoek's seventeenth century resolving power of 1.25 μm had barely been improved on but the work of J. J. Lister on achromatic objective lens systems was just beginning to open up new horizons. By 1880 the resolution of the best microscopes was down to 0.2 μm and the society's aim to introduce and improve the microscope 'as a scientific instrument' began to be achieved.

Communication amongst microscopists depends very much on quality reproduction but the society was hardly in the forefront of publishing photomicrographs. It had published its first in 1853 (the ubiquitous proboscis of the fly) but it was not until 1906 that the *Journal's* lithographs began to be supplanted by photographs.

After 1890 there was little fundamental technical development possible for the optical microscope and the society went into a long period of decline. "Hibernation" one of its officers says, "is too mild a word for it". The question is whether the society has now been able to catch up with the lost opportunities of the dormant period and whether it will be able in the future to exert influence in the development of microscopy—now, of course, including electron microscopy. Many of the educational activities such as teacher training, provision of a technician's qualification and the publishing of teaching manuals, the bread and butter of many professional societies, are only now being planned. Another field that one fellow described as needing urgent attention is the "abysmally low" general standard of photomicrograph reproduction in books. Yet another problem is that a certain introversion and inscopists seem to possess, perhaps feeling their profession is merely a service industry.

The society has a hard pull ahead of it with much unglamorous work to do in establishing educational programmes. If it fails in its appeal, it will revert to a journal-producing and symposium - organising society, and science will suffer thereby.

Computers and social options

from the staff of La Recherche

FOR the first time at the international level, information scientists and computer architects, sociologists and trade union representatives met earlier this month in Vienna to try to cope with the nagging issue of "Computers and Human Choice". Organised under the auspices of the 35-nation International Federation for Information Processing (IFIP) and the Austrian Cybernetic Society, the conference nicely complemented a symposium held two months earlier in Amsterdam, when the International Federation for Automatic Control pondered the problem of "Productivity and Man". Both meetings are clear evidence of the concern shown by professional societies for how today's machines are amplifying human mind and muscle and where the mechanical surrogate leaves man.

The job which the IFIP has set for itself is a big one: in the words of its president, Heinz Zemanek, it is "to stress the social aspects of the computer —to re-establish the human being as the centre of our existence". Large scale information systems have been motivated, to date, largely by industrial and commercial needs. (The military compulsions were not treated by the conferees at Vienna.) Harold Sackman (RAND Corporation) estimated, for example, that the public treasury of the United States has spent about $100 thousand million thus far "on the development of computer services of all kinds, and the rest of the world has spent probably the same amount. But the individual citizen is the last to see a direct, useful return on his investment." Or, as expressed more effectively by John M. Carroll (University of Western Ontario), "the computer may be regarded by some as a repressive instrument which serves the causes of governments, corporations and large institutions. The common man too often sees himself as billed by them, taxed, enumerated, administered, manipulated, controlled—creased, folded, spindled and mutilated."

There is hope, nonetheless, that the social options open to the wizards of computing will prove to be more humane in the years to come. Citing a recent report by the Japan Computer Usage Analysis Institute, Alfred Dallinger of the Austrian trade union of white collar workers reminded the meeting of the following time spread noted by the Japanese in the application of large scale information handling systems: 1945–70, 'big science,' 1955–80, the management base, and 1980–2000, the individual base.

With this projection in mind Ulrich Briefs (West German Trade Union Federation at Dusseldorf) noted that one of the key problems in the long range strategy of organised labour is "whether it is better to fight for an improvement of the situation of employees . . . with no involvement in management decisions or . . . it is more advantageous to participate actively and cooperatively." In other words, does the noninvolvement of the employee in the management process lead to worker alienation? Kristen Nygaard, a computer scientist who is also an executive of Norway's labour union federation, could foresee that trade unions would help improve system design as labour becomes better informed, "as it acquires more information and, therefore, more power in the management–worker relationship. I could not see the unions in my country," he added, "approving the installation of visual terminals on

the shopfloor unless these were two-way links."

That the computer is not devoted principally to inventory and marketing problems or to payroll and insurance calculations was evidenced by some of the extensive (and impressive) social applications found for the computer in different geographical and ideological settings. G. R. Waddell, computer comptroller of the Edinburgh Corporation, explained the enormously complex base of accounting, personnel and multiple urban data comprising the municipal management information system (MIS) required to run the city of Edinburgh. Carroll described the experience in London (Ontario) of installing a "people's computer as an aid to democracy", of providing "the common man with easy access to computer facilities to even up the social, economic and political balance of power" in the form of a nongovernmental urban information service in that community. And Burt Nanus, director of the Center for Futures Research at the University of South California, recalled that a Delphi study made for the American Federation of Information Processing Societies showed how MIS could "strengthen multinational public enterprises in such areas as [education] public health, criminal justice, pollution control, weather forecasting and disaster control, with major impacts before 1985".

An area of principal concern to the IFIP colloquium was that of fair information practices. Bo Hedberg (International Institute of Management, Berlin) emphasised that "we are approaching an information-rich society". System design of the means to process these data usefully, Hedberg continued, "is concerned with the distribution of power, implicitly or explicitly". Willis Ware, an engineer at RAND, proposed the creation by legislative action of a "code of fair information practice or perhaps an Informational Bill of Rights" in an effort to define, nationally then internationally, what is fair behaviour in this realm, "establishing safeguards and deterring deviation by judicial process and appropriate penalties". The IFIP agreed that it will examine the optimal methods, through an *ad hoc* computers-and-society committee, in order to deal with this and similar issues raised during the week-long deliberations.

Although some expressed the apprehension that "the electronic world is passing us by as we sit here debating—Nero fiddling while Rome burns," the last and far from pessimistic word on the subject went to the venerable, Russian-born physicist Lew Kowarski (CERN). He underlined his trust in man's use of the computer when he declared that the latter, "while it will relieve us of burdens, could also relieve us of all that makes life worth living. Before I count on the unforeseen—and therein lies our hope, albeit a pious one. The danger in computers comes not from the experts, but from the profiteers."

Australian answer

Peter Pockley, Sydney

AFTER studies by various Australian government departments, the Russian request to set up a joint facility "for photographing space objects and studies of the upper atmosphere," reported recently in *Nature*, has been rejected. The announcement was made on the same day that Prime Minister Whitlam called a snap general election. In the election atmosphere, the Labour Party could not afford the predictable attacks on grounds of favouring communists above capitalists, even if the scientific arguments in favour of the facility had been sound.

news and views

Maternal transmission of hepatitis

INTEREST in the transmission of viral hepatitis from the mother to her offspring is not new. The effects of hepatitis on the course of pregnancy and on the foetus have been studied since the report by Saint-Vel in 1862 on an epidemic of severe hepatitis in pregnant women in Martinique (*Gaz. Hôp. civ. milit. Paris*, **35**, 538; 1862). The world literature contains scanty and incomplete data and numerous divergent views. Stokes and associates (*J. Amer. med. Ass.*, **514**, 1059; 1954) presented evidence of 'silent carriage' of hepatitis B virus, and it is relevant to examine this paper in detail now that specific laboratory tests are available for hepatitis B and the problem of maternal transmission of this infection is being actively investigated.

One carrier described by Stokes was known to have transmitted hepatitis to at least four out of twelve recipients of his blood over a period of 3 years. His blood was also administered to four male volunteers, one of whom developed hepatitis. The second carrier is of particular interest. She was the mother of an infant who developed hepatitis at the age of 2 months. Volunteers given serum from her and her infant developed hepatitis. The third carrier was known to have transmitted hepatitis to four recipients of his blood, including one volunteer. The impact of apparently healthy carriers of hepatitis B virus on blood transfusion services and indeed on every aspect of medical practice is generally recognised. The problem of maternal transmission is just beginning to emerge.

Turner and colleagues (*Archs Dis. Childh.*, **46**, 616; 1971) reported the case of a young man who contracted hepatitis B after injection with an unsterile syringe. His wife, who was pregnant, developed the infection some 9 weeks later and her baby was born prematurely. After 59 days hepatitis B antigen was detected in the child's serum and antigenaemia had persisted so far through the first 2 years of life. The child remained clinically well but with some biochemical evidence of liver damage. Wright and associates (*Brit. med. J.*, **4**, 719; 1970) previously described the clinical history of a young dental assistant who developed jaundice late during her pregancy. She was delivered of a normal female infant who, in turn, became jaundiced at the age of 5 months. Hepatitis B antigen was detected repeatedly in the infant's serum and in the mother's serum tested when the infant was admitted to hospital. Liver biopsy of the infant at the age of a year revealed chronic active hepatitis and cirrhosis. The mother, on the other hand, had remained symptom-free and her liver function tests were normal. Ohbayashi and colleagues (*Gastroenterology*, **62**, 618; 1972) tested sera collected in Japan from fifty-four members of three families with chronic liver disease or primary liver cancer. Hepatitis B antigen was detected in fourteen of fifteen affected members of the families and their siblings and in twenty of the twenty-four children of the female siblings. By contrast, the antigen was detected in only one of the eight children of the male siblings, and the antigen was found in the serum of his mother.

The finding of the antigen in these three families coincided remarkably well with the distribution of severe chronic liver damage or primary liver cancer in the family tree. Familial clustering of cirrhosis has been reported in ten families in Japan since 1963. Of the thirty-nine affected members of these families, eleven died of cirrhosis and nine died of cirrhosis and liver cancer. It is notable that successive occurrence of liver disease for two generations was recognised in seven of the ten families, and the mother or her siblings were affected in each family. The next report by Merrill and her colleagues (*New Engl. J. Med.*, **287**, 1280; 1972) illustrates the other end of the spectrum. Of five children born to mothers who had hepatitis B infection at the time of delivery, four acquired the antigen 6–12 weeks after birth, but they remained clinically well and fulfilled the criteria for symptomless carriers. The fifth mother–child case is of interest in that the infant had hepatitis B antibody in his serum at birth (as did his mother) and he did not acquire the antigen.

Schweitzer and colleagues (*Gastroenterology*, **65**, 227; 1973) investigated some of the factors influencing neonatal infection by hepatitis B virus. A striking difference in the frequency of infection was noted between infants of mothers who had acute hepatitis B and those who were symptomless carriers of the antigen. Thirteen babies of twenty-seven mothers with the acute disease acquired persistent antigenaemia, especially if the maternal illness occurred near the time of delivery. By contrast, only one of twenty-one symptomless maternal carriers had a child who became antigen positive. The antigen was detected by radioimmunoassay in nearly half of twenty-one umbilical cord sera tested. The placental barrier to the antigen did not seem to differ in the acutely infected mother from that in the healthy carrier, and the presence of antigen in the cord blood was not necessarily related to subsequent acquisition of the antigen by the infant. In another report, Schweitzer *et al.* (*Amer. J. Med.*, 55, 762; 1973) noted that the frequency of transmission of hepatitis B from mother to infant was high (76%) when acute hepatitis B occurred during the third trimester of pregnancy or early in the postpartum period, and low (10%) when hepatitis occurred during the first 6 months of pregnancy. Acute hepatitis developed in two of seventeen infants and the illness in both was mild, antigenaemia was transient and the homologous antibody developed during convalescence. No clinical illness was observed in thirteen infants (two infants were lost to the survey), but the antigen persisted in their serum accompanied by prolonged elevation of an enzyme frequently associated with liver damage. Liver biopsy performed on ten infants revealed this histological features of unresolved hepatitis and increased portal fibrosis was present in one infant. On electron microscopy, virus-like particles were found in the nuclei of six out of nine antigen-positive infants examined. Dunn and colleagues (*Exp. molec. Path.*, **19**, 113; 1973) found virus-like particles in explant cultures prepared from the remaining portions of some of these biopsies and they concluded that the particles proliferated within the nuclei of the liver sells.

In a more recent study on maternal transmission of hepatitis, Mazzur *et al.*, (*Nature*, **274**, 41; 1974) determined the subtypes of hepatitis B antigen in 174 positive sera collected together with pedigrees in eighteen villages in south central Bougainville, an island in Oceania. Two different combinations of antigens were segregating in eleven out of thirty-two families tested, indicating that

these carriers had not been infected by each other nor from the same source. In families where the mother was a carrier, however, the twenty-two children who had antigenaemia had, with a single exception, the same subtype as their mother. Among the twelve families where the mother was positive only one had mixed subtypes; while ten out of twenty families in which the mother did not carry the antigen had antigen of different subtype. Among six families in which the father was positive, mixed subtypes were found in four of the families.

The data thus suggest that vertical transmission from mothers to their children occurs, and also that horizontal transmission clearly takes place. Although vertical transmission and perinatal transmission from mother to child occur, the relative importance of each mode of transmission is not yet determined.

The significance of hepatitis B infection in early life lies not only in its relation to liver disease but also in its importance in the genesis of prolonged carriage of hepatitis B viris. Zuckerman and Taylor (*Nature*, **223**, 81; 1969) described a well-documented healthy former blood donor carrying hepatitis B antigen for at least 20 years. That a reservoir of chronic carriers may become established among children is, therefore, a cause for the utmost concern to the community. Methods for passive immunisation of susceptible newborn infants are already under evaluation, but the need for safe and effective vaccines is pressing. As a corollary the serum of pregnant women should now be routinely examined for hepatitis B antigen.

ARIE J. ZUCKERMAN

More to muscle than myosin

IN ways not anticipated, myogenesis has yoked in an uneasy alliance muscle biochemistry, molecular genetics and cell differentiation. The finding of Ishikawa and colleagues (*J. Cell Biol.*, **43**, 312; 1969) that arrow-head complexes—the *sine qua non* of actin—can be induced by H-meromyosin in the cortical regions of cartilage, nerve and intestinal epithelial cells, as well as in many kinds of embryonic cells, has been confirmed in many laboratories. Adelstein and colleagues (*Proc. natn. Acad. Sci. U.S.A.*, **69**, 3693; 1972) and others have found myosin in platelets, fibroblasts and nerve cells. Tropomyosin, the third of the contractile protein triumverate, has also been found in several cell types (Cohen and Cohen, *J. molec. Biol.*, **68**, 383; 1972). Clearly many kinds of cell synthesise molecules identical or similar to actin, myosin and tropomyosin—molecules not long ago thought to be unique to terminally differentiated muscle cells.

Such results might satisfy the egos of muscle biochemists, but perplex those attempting to understand cell differentiation. Current models assume that the differentiated state is based on the activity of different sets of genes in different kinds of cells. A possible resolution of the dilemma of ubiquitous contractile proteins, and one with considerable theoretical implications for other aspects of differentiation, is the notion that there are several structural genes for different myosins and different tropomyosins, and that in different kinds of cell different myosin and tropomyosin genes are transcribed. Consistent with this scheme is the finding that the myosin light chains and the LMM portion of the myosin rod are products of different structural genes in fast, slow, smooth and cardiac muscles. Possibly during the differentiation of fast muscle, only those structural genes for fast myosin and fast tropomyosin become available for transcription and translation, whereas during the differentiation of platelets or cartilage cells two other sets of genes for myosin and tropomyosin become available. This means that the genes for platelet or cartilage myosins are no more available in skeletal muscle cells than are the genes for albumin or pituitary hormone.

This ready solution, regrettably, is not as likely to explain the role of actin in the developmental programmes of virtually all cells. The issue with this strikingly conservative protein is whether the products of a single structural gene can be coupled to different kinds of myosins and tropomyosins, or whether there are several identical actin genes possibly even in different chromosomes participating in different developmental programmes. Circumstantial evidence for the latter stems from experiments showing that bromodeoxyuridine (BUdR)-suppressed myogenic cells

If at first you don't succeed . . .

RADIOASTRONOMERS are about to begin another programme of 'listening' for signals from intelligent life within our Galaxy. Since the days of the original Project Ozma a decade and a half ago, radio observing equipment and techniques have improved and the rationale behind such a search has become more sophisticated. Previous efforts chiefly concentrated on hydrogen frequencies, since hydrogen is the most abundant element in the Universe. But recently there has been a growing feeling that any really intelligent race would probably preserve just these frequencies as free from artificial noise, because of their importance to radioastronomers. So the new investigation, which begins on May 8, will be using frequencies appropriate to emission from water.

The rationale behind this is partly the importance of water to life as human beings know it. In the wild, creatures meet at the water hole, so why not try the same sort of thing for contact between ourselves and extraterrestrial creatures? The frequencies are also ones which have been found in natural astronomical sources, notably clouds of gas and dust believed to be associated with young, forming stars. They are not expected to occur naturally in the region of older stars, which improves the likelihood that any such 'signal' from near such a star is a sign of life.

The astronomers responsible for this particular investigation are P. Feldman, of York University, Ontario, and A. Bridle of Queen's University, Kingston, Ontario; their programme involves the 150-foot Algonquin telescope, and is a "passive" one—Bridle is reported as saying that "we would not be capable of sending a signal our own equipment could detect over interstellar distances". Some six stars will be studied intensively from time to time (the first observing period devoted to the programme is 5 days) and 300 to 500 stars will be looked at more briefly over a year or two. The targets have been chosen on the basis that they are non-variable, slowly rotating (and so likely to have planets) and middle-aged (so that intelligence has had time to evolve).

News of this project arouses mixed feelings, since the 150-foot is a valuable instrument that might arguably be used for 'better things'—in the sense of studies which would definitely produce results. But 5 days here and there need be no great loss, and there will, of course, be no quibbling about the project if the North American team hit the jackpot.

JOHN GRIBBIN

synthesise actin destined for the cell surface, whereas actin for thin filaments does not accumulate.

These considerations require re-evaluation of reports of the time during myogenesis when the messenger RNAs for myosin are transcribed and translated. If the presence of a molecule with the molecular weight of 200,000 is taken as evidence for the synthesis of myosin (Yaffe and Dym, *Cold Spring Harb. Symp. quant. Biol.*, **37**, 543; 1972) then all cells, including replicating presumptive myoblasts, must be transcribing and translating mRNAs for some kind of myosin. Accordingly it is not surprising that Rubinstein and colleagues (*Biochem. biophys. Res. Commun.*, **57**, 438; 1974) now report that myosin and actin are indeed coordinately synthesised and turned over, not only in myotubes but also in mononucleated presumptive myoblasts, cartilage cells, fibroblasts and BUdR-suppressed myogenic cells.

Lastly, a smouldering controversy of considerable interest to molecular geneticists exists between those who claim that myoblasts withdraw from the cell cycle as a precondition to fusion, and those who claim that cessation of DNA synthesis results from fusion. The most emphatic statement of the second position is that of Doering and Fischman (*Devl Biol.*, **36**, 225; 1974). Based on what is termed a "% fusion" index they conclude that myogenic cells whose DNA synthesis is blocked by Ara-C fuse; according to these authors replicating myogenic cells have the option to replicate, or to fuse, and, as a consequence of fusing, cease replicating. Before these important conclusions can be accepted, however, it should be noted that: (1) Ara-C is routinely used to kill replicating cells, so that the design of the Doering and Fischman experiment must yield a spuriously high "% fusion" index; (2) early fusion cannot be measured with the light microscope; and (3) it is impossible to distinguish 'fibroblasts' from presumptive myoblasts. Given these uncertainties it will be interesting to see if those who speculate that myoblasts withdrew from the cell cycle as a precondition to fusion can devise more cogent experiments.

H. HOLTZER

Slaved disk model for Hercules X-1

from James Pringle

A POSSIBLE solution to some of the more puzzling aspects of the X-ray star Hercules X-1 has been proposed in a recent article by Roberts (*Astrophys. J.*, **187**, 575; 1974). The X rays from Her X-1 are regularly pulsed with a period of 1.24 s and the source of X rays is one member of a binary star system which has an orbital period of 1.7 d. The X-ray source is thought to be a neutron star with a strong dipole magnetic field and the X rays are produced by material transferred from the 'normal' star of the binary system accreting on to the compact neutron star. Because of the strong magnetic field, the accreting material is channelled down on to the magnetic polar caps of the neutron star dissipating its kinetic energy of infall when it strikes the surface. So much energy is liberated in such a small region that the temperature rises to more than 10^7 K. Thus most of the radiation emerges as X rays. The two magnetic polar caps are then two X-ray emitting hotspots: if the magnetic axis is offset from the rotation axis, rotation of the star with a 1.24 s period provides a natural explanation of why the observed X rays are regularly pulsed.

Furthermore, the X-ray source displays a third periodicity. The X rays are visible for only about 10 to 12 consecutive days, reappearing regularly at 35-d intervals. Explanations of this phenomenon—for example, variable mass transfer or precession of the pulsing neutron star—have difficulty in accounting for another aspect of the problem. The 'normal' component of the binary system was identified in 1972 as the previously known variable star HZ Herculis. This star is so close to the luminous X-ray source that X-ray heating causes one side of it to be about four times brighter than the other. The brightened face follows the neutron star around its orbit, and thus HZ Her can be observed to vary regularly in brightness with a period of 1.7 d. The puzzling feature of this 1.7-d optical variation is that, although the X rays can be seen for only 10 out of every 35 d, the heating of the side of HZ Her nearest to the X-ray source continues throughout the cycle, even when no X rays are observed.

Roberts' explanation of this is quite simple. He suggests that HZ Her has its rotation axis at an angle to the orbital rotation axis. In this case, the rotation axis of HZ Her precesses about the orbital rotation axis with a period of about 35 d. The material transferred by HZ Her towards its companion has too much angular momentum to be able to fall on to it directly and, instead, forms an accretion disk around the neutron star. In the disk, viscosity transfers angular momentum outwards, allowing the material to spiral slowly inwards. Roberts notes that the disk, which is opaque to X rays, will lie in the plane perpendicular to HZ Her's rotation axis, and thus in general not in the orbital plane of the system. Roberts names this the Slaved Oriented Disk, or SOD for short. Thus the angle between our line of sight to the X-ray source and the plane of the SOD varies with the 35-d precession period of HZ Her. Since the X-ray source can only be seen when this angle is sufficiently large, one expects the visibility of the X rays to vary with the 35-d period. On the other hand, HZ Her is so close to the X-ray source that the (X-ray) shadow cast on its surface by the disk is quite small. Thus one expects the heating of HZ Her to continue, even when the disk temporarily obscures the X-ray source from observation.

This is by no means the whole story. Roberts also explains why the rotation axes might be expected to be misaligned and shows how his model can account for several further observational details. There are now a number of models which seem to account for the 35-d period of Her X-1 and its associated problems, but nobody has yet performed any detailed calculations. Roberts, however, excuses himself by quoting J. A. Wheeler's First Moral Principle: "Never do a calculation until you already know the answer".

Asia as a composite continent

from Peter J. Smith
Geomagnetism Correspondent

WHETHER or not it is realistic to suppose that any of the present continents could have formed by the accretion of separate crustal blocks, the important question of continental fusion continues to receive considerable attention. Most recently the debate has centred particularly on Africa (see, for example, Piper *et al.*, *Nature*, **245**, 244; 1973) with new evidence suggesting that the orogenic belts between the major cratonic areas of that continent may not be sutural but more probably formed *in situ*, although the idea of what Kropotkin (*Eos*, **53**, 180; 1972) has termed the "composite continent" was actually first applied to Asia by Argand (*Coll. Rep. 13th Int. Geol. Congr. 1922*, **1**, 171; 1924) just 50 years ago and long before the new global tectonics had been thought of.

Since then, evidence supporting the composite nature of Asia has been adduced from palaeomagnetism, palaeontology, geology and petrotectonics. In a useful and commendably concise article Burrett (*Earth planet. Sci. Lett.*, **21**, 181; 1974) has now brought all these data together to delineate the Asian block boundaries and to estimate the timings of the various collisions thought to be involved. Although the field information is not entirely clear in all cases, there seem to be about nine blocks present; and Burrett sum-

marises the evidence for each.

The general conclusion that Burrett comes to is that the coincidence of orogenic belts containing zones of high pressure metamorphism, ophiolites and deep water sediments with faunal province boundaries only makes sense in plate tectonic terms, the belts being the sutures along which the crustal fragments collided and coalesced. He then goes on to discuss when these collisions took place, beginning with the assumption that in the Lower Palaeozoic the various blocks were separated by considerable widths of oceanic crust. According to this analysis the first collision took place in the Upper Carboniferous, although the fusion of all blocks into what is now Asia was not complete until well into the Mesozoic.

Burrett admits that his model is based on "very incomplete data" but nevertheless suggests that "there does not appear to be much room in which to alter the boundaries of the blocks here identified nor the timing of their collisions". It remains to be seen whether, as in the case of the African orogenic belts, a static model can be made to explain the data even more convincingly.

Sources of natural radiation

from J. R. A. Lakey

THE largest source of ionising radiation exposure to the United Kingdom population originates from terrestial and cosmic radiation. This natural radiation was the subject of a meeting of the Society for Radiological Protection held on April 2. C. R. Hill (Institute of Cancer Research, Sutton) stressed that the exposure is by no means uniform. The living habits of human beings have a marked effect on the dose because of the natural radionuclides in the diet and the radioactivity of building materials. These differences have been exploited—in attempts to deduce a dose/effect relationship—but with little success because control populations are hard to find. Nevertheless there has been some pressure to use the apparently solid ground of natural radiation exposures as a basis for setting radiation protection standards. The International Commission on Radiological Protection has not made its recommendations on this basis but J. Vennart (Medical Research Council, Radiobiology Unit, Harwell) reminded the society that natural radiation is deliberately neglected and controls are applied only to artificial radiation exposure.

An interesting dilemma arises from the use of building materials which are naturally radioactive. G. A. M. Webb (National Radiological Protection Board, Harwell) revealed that the Soviet Union has limits designed to avoid 'abnormal' radiation exposure and prohibits building materials containing more than 10 pico curies of radium-226 per gram. Most building materials are not significantly radioactive so that the house walls and foundation act as a shield against natural radiation exposure.

Several speakers referred to the more insiduous radon-222 which is present in air at around 0.1 pico curies per litre and in some cases appears in drinking water at concentration as high as one million pico curies per litre. E. I. Hamilton (Institute of Marine Environmental Research, Plymouth) said that the apparently inexplicable variations in the activity of radon in drinking water occur because the gas can move through the crack system from rocks as deep as 3,000 m.

The dose from natural radiation has been reviewed extensively by the United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR). F. W. Spiers University of Leeds) discussed the dose due to internally deposited radioactivity, and said that doses reported by UNSCEAR for cortical and trabecular bone should be revised. The fat cells, which account for 53% of bone marrow, concentrate carbon-14 and the dose becomes four times higher than UNSCEAR reported. Surface-seeking alpha emitters also increase the dose to osteoblasts lining the cavities in bone. The genetic effect of natural radiation has been of most concern to human populations and it must account for some of the births subject to genetic disease. R. J. Berry (Royal Free Hospital, London) said that the radiation dose to double the mutation rate is thought to be between 30 to 80 roentgens. Nobody has been able to correlate natural radiation dose with genetic diseases and it is not necessarily correct to assume that all mutations are harmful. Indeed there is some evidence to suggest that some radiation-induced effects are repaired.

Sendai virus receptors in a model membrane

from a Correspondent

VERY little is known about the first step in replication of animal viruses—the absorption of the virus to receptors of the host cell. It is surprising, for instance, that the question of whether the small oncogenic DNA viruses bind to specific cell receptors is still unresolved. By contrast, the complementarity involved in the reaction of myxoviruses and paramyxoviruses, such as Sendai virus, with specific receptors, at least in the non-permissive erythrocyte, is well known. Haywood (*J. molec. Biol.*, **83**, 427-436; 1974) has extended this system to a study of the interaction of Sendai virus with a model membrane incorporating the specific receptors.

Electron micrograph of Sendai virus adsorbed to a ganglioside-containing liposome. The virus can be distinguished by the spikes on the outer surface. The length of the attachment of the two viruses is 2,100 and 2,500 Å. The bar represents 1,000 Å. (From Haywood, *J. molec. Biol.*, **83**, 427; 1974.)

Sendai virus has a spiked appearance, the spikes being surface glycoproteins which absorb to sialic acid groups of the receptors of erythrocytes and presumably also of permissive host cells. Haywood now reports that sialic acid groups of gangliosides work well as receptors for Sendai virus if they are incorporated into synthetic lipid membranes at relatively high surface density. Electron micrographs show virus particles absorbed to the liposomes containing ganglioside along long stretches (210 nm–250 nm) of the virion. Assuming the area of attachment to be a circle of this diameter, then it seems that the virion is absorbed to a considerable patch of membrane and makes multiple attachments between spike glycoproteins and clusters of gangliosides, perhaps as many as 3,000. It would be interesting to know if the clustering of receptor molecules is actually induced by binding to the virus. If so, then this process might be related to cell fusion induced by viruses such as Sendai, since high local concentrations of gangliosides destabilise lipid bilayers.

The absorption of Sendai virus to

liposomes is specific for structures containing gangliosides or a positive lipid such as stearylamine. The types of binding to these two sorts of liposomes are clearly differentiated, however, since only the membranes which incorporate the sialic groups can compete effectively for virus in mixture with erythrocytes. The weak nonspecific binding of Sendai virus to liposomes containing stearylamine is probably electrostactic since the virions have a net negative charge.

The way in which sialic acid groups are presented to the virus is of prime importance for high affinity binding. For example, very small liposomes containing gangliosides obtained by sonication are less potent inhibitors of viral haemagluttination than are liposomes with a greater total surface area. Second, ganglioside micelles do not compete with erythrocytes for virus. Probably both a threshold surface area and ganglioside density are needed in order that the virus can make a critical number of contracts with the absorbing surface. A somewhat similar interpretation probably explains the finding, made earlier by several groups, that the tightness of binding of myxoviruses to sialoglycoproteins depends critically on the molecular size and is drastically decreased by proteolysis of the receptor glycoproteins. The reason that a large number of contacts are required for firm attachment to receptors containing sialic acid might be explained if the bond energy between receptor groups and viral spike glycoproteins is low.

Whether gangliosides or sialoglycoproteins or both are the naturally important receptors for Sendai virus in cells which support a lytic infection is unknown. Haywood suggests that the probable topography of the cell surface is such that the first viral contacts may be with glycoproteins, after which virions are handed over to gangliosides situated nearer to the bilayer and in a better position to initiate events leading to penetration. Perhaps this process involves the viral neuraminidase in localised reactions which break the initial binding of virions to receptor glycoproteins and allow attachment to internal gangliosides to take place.

New advances in SEM

from a Correspondent

AT the seventh Annual IIT Research Institute Symposium on Scanning Electron Microscopy in Chicago from April 7 to 11, probably the most significant advance in instrumentation was that reported by O. Wells and A. Broers (IBM Research Laboratories). These workers immersed the specimen in the high field region of the final lens and collected the low energy loss electrons coming from the edge of a highly tilted specimen. They were then able to demonstrate centre/centre resolution of 3 nm and an edge resolution of 1.5 nm. The instrument used was the 100 Kv LaB_6 gun designed by Broers, who thought that the resolution could now only be further improved by using a single crystal of LaB_6 to replace the finely pointed sintred rod.

M. Isaacson (University of Chicago) presented a frank discussion of the problems associated with specimen preparation for the high resolution scanning transmission electron microscope presently under development in several laboratories. Although the instrumental potential now exists for atomic resolution, specimen contamination and beam damage represent real problems which must be solved before a wide range of biological macromolecules are going to be imaged in these new microscopes. Isaacson and his colleagues considered the answer to these problems lay in the use of LHe II stages, low atomic weight negative stains and computer image processing to remove background noise.

Several speakers discussed real-time stereo viewing and dimensional reconstruction of stereo pairs. A. Boyde (University College, London) outlined the problems associated with such reconstructions and demonstrated the usefulness of the method in analyses of complex tri-dimensional objects and in interpreting dynamic experiments in the microscope. But the most convincing demonstration of real-time stereo viewing was given by E. Chatfield and colleagues (Ontario Research Foundation). By using a single post lens deflection coil they took a dual signal which was displayed on a colour TV set utilising the red and green guns. The image could then be viewed using red and green separation filters in order to reconstitute the 3D image.

N. Barbi and colleagues (Prairie View, Illinois) gave some data on a windowless energy dispersive X-ray detector in which it was claimed that they are able to get significant signals for C, O and N though problems of contamination and beam collimation still remain. There were several comments on some of the ancillary techniques associated with SEM, including advances in cathodoluminescence, autoradiography and histochemistry. None, however, demonstrated the necessary breakthrough which would make these techniques of any significant use in scanning microscopy. In the biological sciences, J. Nowell (University of California at Davis) gave more details of the injection replication technique for internal cavities of animal tissue and W. Humphreys and colleagues (University of Georgia) outlined a useful variation on the critical point drying technique which enables cryofractured specimens to be visualised in the SEM.

Scanning electron microscopy seems to have come of age and there are now more than 25 different models of microscope from which to choose. The IITRI SEM symposia have played no small part in the growth of the subject and it will be of interest to see whether future meetings can continue to contribute to the requirements of scanning electron microscopists and not degenerate into a dreary catalogue of photographs of what can be seen using this instrument.

Activation energies under scrutiny

from our Chemical Physics Correspondent

FOR many years discussions of thermal reaction rates have centred on the activation energies, E, of reactions whose rates have followed the Arrhenius expression, $k = A \exp(-E/RT)$ and its more modern variants. Its justification requires reagents to possess the energy E in order to surmount an energy barrier and proceed to reaction. The degrees of freedom holding the energy were considered irrelevant except that their number might influence the factor A. It has long been recognised that this assumption was not fully correct but experiments to show the specific influence of particular categories of initial energy have not been easy to devise.

In recent years a number of cases have been studied where the excess energy of the products of an exothermic reaction has resided in specific vibrational excitation. The principle of microscopic reversibility then requires that analagous reactions in the reverse direction should proceed preferentially with the reagents in excited vibrational states. It is just such a process which has been elegantly demonstrated by Douglas, Polanyi and Sloan at Toronto (*J. chem. Phys.*, **59**, 6679; 1973).

The reaction chosen was

$$HCl + Br \rightarrow HBr + Cl$$

for which the HCl reagent could be prepared in excited vibrational states from the reaction

$$HI + Cl \rightarrow HCl\ (v = 1 \text{ to } 4) + I$$

Such a stream of vibrationally excited states was crossed with a stream of Br atoms which was pulsed on and off 15 times a second. The occupancy of the vibrational levels of the HCl was monitored through the infrared emission spectrum and the change between the on and off periods for the Br was simultaneously obtained by means of a phase sensitive detector set to 15 Hz. The frequency setting of the spectro-

meter monitoring the emission was swept and its resolution was such that each separate vibration–rotation state characterised by v and J could be monitored. As expected it was found that whereas the levels $v = 1, 2, 3$ and 4 were easily seen in emission, the depletion of these levels by reaction with Br for $v=$ was greater than for $v = 3$, but changes in the populations of the levels $v = 2$ and 1 by reaction were scarcely detectable.

Although this result in itself is not surprising and leaves the principle of microscopic reversibility intact, the elegance, comparative simplicity and excellent sensitivity of the technique imply that its future sophistication will lead to considerable detailed experimental evidence about reaction energy surfaces. This should prove valuable in a field where theory has tended to outrun experiment.

Double repression of galatose genes

from Benjamin Lewin
Molecular Genetics Correspondent

THE interactions which control repressible and inducible operons in bacteria are now well understood in principle: in the lactose operon, for example, repressor protein, cyclic AMP receptor protein (activated by cyclic AMP) and RNA polymerase act at sites on DNA close to the structural genes under control. The galactose operon, however, is a more puzzling system than usual, and it has been difficult to envisage molecular mechanisms for its control. By characterising a new regulator mutation, Hua and Markovitz (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 507; 1974) have now identified a new control site in the operon, analysis of which may help define this system.

The galactose operon is controlled by three systems. A repressor protein (specified by the regulator gene gal^R) inhibits transcription in the absence of galactose by binding to an operator (defined by mutation) located at one end of the structural gene cluster. The cyclic AMP receptor protein and RNA polymerase interact at a site (presumed to be close to this operator) to initiate transcription. The third system of control establishes repression in response to the cap^R gene, which is part of a regulator system responsible for controlling synthesis of products required for formation of the capsular polysaccharide. Because mutations in the gal^R and cap^R genes each relieve only some of the repression of the operon, and appear to act independently, it has seemed likely that the galactose operon might possess two operators.

This hypothesis has now been confirmed by the results reported by Hua and Markovitz. Operator mutants lacking response to an active gal^R locus have in the past been isolated; and these identify the operator at which galactose repressor protein binds. By selecting cells which do not respond to an active cap^R gene, they obtained a mutant with the characteristics expected of an operator unable to respond to the cap^R product. The mutation is closely linked to the first structural gene of the operon.

Since the cyclic AMP system stimulates transcription *in vitro*, it seems very likely that, analogous to the lactose operon, it acts at a promotor adjacent to the galactose operator responsive to gal^R product. That the second operator, on which the cap^R product acts, may also be accompanied by a promotor, this one unresponsive to the cyclic AMP system, is suggested by the observation that bacteria deficient in cyclic AMP can grow on galactose. From the characteristic of mutants affecting expression of the galactose operon, Hua and Markovitz suggest that the gal^R responsive sites lie immediately adjacent to the structural genes, with the cap^R responsive sites lying just beyond them.

Obvious topological problems are raised by the presence of two operators in one operon. How does repression at one influence transcription from the other? Given present models for repressor–operator interactions, it is not immediately obvious how expression from the further control sites takes place when the inner sites are repressed. And when both sites are supporting transcription, one might expect changes in the state of DNA to occur as polymerases readthrough the inner sites—do these influence its activity?

How may these control systems be better characterised? One obvious experiment is to map the two operators more precisely to determine their order and distance apart. Also important is the necessity of characterising the promotor(s) by mutation, since their postulated properties have been inferred almost exclusively from biochemical experiments. It will be interesting to see whether the two operator and promotor sites are indeed each independent or instead represent overlapping sequences in one region of DNA. Isolation of the cap^R product is another urgent necessity, since this may permit experiments *in vitro* to characterise the mechanism of transcription. Even with such critical points yet to be elucidated, however, one important conclusion is clear: an operon may be controlled by more than one repressor protein and may have more than one operator sequence. This has obvious implications for control of gene action in eukaryotic cells.

Interplanetary dust on Earth

from Peter J. Smith
Geomagnetism Correspondent

EXTRATERRESTRIAL material captured by the Earth is generally believed to comprise mainly interplanetary dust, the more spectacular contribution from meteorites being relatively small. Unfortunately, however, not only is interplanetary dust much more difficult to identify than meteoritic debris, there are also likely to be problems in separating it from the terrestrial material in which it is highly diluted. The result is that the nature of most of the material reaching the Earth from outside remains largely unknown. On the other hand, there is no reason in principle why the products of interplanetary dust on Earth, if they exist, should not be identified. Wasson (*Icarus*, **2**, 54; 1963), for example, showed that the presence of extraterrestrial dust would be proved if radioactive nuclides produced by the action of high energy (5-100 MeV) solar protons on the dust in interplanetary space could be detected in terrestial materials. It is true, of course, that most of these radionuclides may also be produced from spallation reactions induced by galactic cosmic rays; but although such processes are predominant in meteorites they are fortunately negligible in bodies smaller than about 1 cm.

The detection of extraterrestial dust by radionuclides thus seems promising, although even here there is a practical problem in that some of the expected nuclides are also produced on Earth by other natural nuclear processes. ^{26}Al, for example, seems particularly attractive because of its high rate of production, its long half life (0.7×10^6 yr) and its β^+ radiation which is relatively easy to detect. But unfortunately it is also formed by spallation of atmospheric argon at a rate apparently comparable to that expected from processes involving interplanetary dust. The precise relative importance of terrestrial and extra terrestrial ^{26}Al is actually a matter of dispute; but as long as the dispute exists, convincing evidence for the presence of extraterrestrial dust is unlikely to be obtained from this particular nuclide.

The only two nuclides suitable from the points of view of production rate and half life and thought to have no significant natural production on Earth are ^{53}Mn and ^{59}Ni. Accordingly, Bibron *et al.* (*Earth planet. Sci. Lett.*, **21**, 109; 1974) have attempted to detect and measure ^{53}Mn in samples of snow from the central area of the Eastern Antarctic Plateau. This site was particularly suitable for the purpose because it is remote from marine, continental and

industrial sources of terrestrial contaminants. Moreover, the average annual temperature is −60° C and the maximum temperature never exceeds 0° C, so that materials precipitated are perfectly preserved and do not diffuse. There is also another important advantage. Although there are no known natural processes on Earth likely to give rise to ^{53}Mn, this nuclide could be produced as a result of thermonuclear bomb tests in the atmosphere. There is apparently no published data which can either confirm or refute this possibility; and so in order to avoid the problem altogether it is necessary to investigate only snow which fell prior to 1952. At the site in question the rate of snow accumulation has been extremely low, making it possible without too much difficulty to collect firn layers deposited well before nuclear testing began.

^{53}Mn was detected in all three samples of snow analysed (corresponding to the period 1935-1950), the average activity being 0.82 ± 0.17 disintegrations per minute per 10^3 tons of snow. This is apparently the first experimental evidence for the presence on Earth of the natural nuclide. But did it really originate from the supposed interplanetary dust? There is, in fact, another possibility—that the ^{53}Mn was produced not from the dust but from the material volatised or dispersed from meteorites during their flight through the atmosphere. To account for the observed ^{53}Mn activity, however, the volatilisation of over 3×10^6 tons of chondritic material would have been required between 1935 and 1950 whereas, in spite of uncertainties in the estimates, it appears unlikely that the actual meteoritic influx exceeded 6×10^4 tons (or perhaps twice that, taking into account objects with pre-atmospheric masses of less than 10^3 g). In short, the meteoritic material available would have been insufficient by a factor of at least 25. Bibron and his colleagues thus conclude that the only possible source of the ^{53}Mn is indeed the interplanetary dust.

Accepting this conclusion they go on to estimate the total global influx of extraterrestrial dust. During the period 1935-1950 the rate of deposition of ^{53}Mn in Eastern Antarctica was $(2.2 \pm 0.5) \times 10^{-5}$ disint. min^{-1} m^{-2} yr^{-1}, although this is not a value which can be extrapolated directly to the whole Earth. It is probable that a significant proportion of the extraterrestrial material volatilises when it enters the atmosphere, becoming fixed on the stratospheric aerosols and thus ultimately being deposited in such a way that the concentration is maximum in temperate latitudes and minimum at the poles and the equator. The deposition in Antarctica should thus represent a lower limit of the average over the Earth's surface. Assuming (in the absence of any more definite information) that the ^{53}Mn distributes itself in a way similar to that of the ^{90}Sr injected into the stratosphere by thermonuclear explosions, Bibron *et al.* estimate the average global deposition of ^{53}Mn to be $(6.6 \pm 1.5) \times 10^{-5}$ disint. min^{-1} m^{-2} yr^{-1}. From this figure it is then possible to show that the interplanetary dust (assumed to have a chondritic composition) accumulates on the Earth at a rate of $1\text{-}6 \times 10^5$ tons a year.

In summary, then, Bibron and his colleagues have provided the first inputable (their word) evidence for the presence on Earth of ^{53}Mn, a radionuclide thought to be formed only from interplanetary dust which builds up on the Earth at a rate of about 10^5 tons a year. But this is only a beginning, for most of the questions about interplanetary dust remain unresolved. As Bibron *et al.* point out, a decisive step forward would be the simultaneous determination of ^{53}Mn, ^{59}Nn and ^{26}Al, although there is still plenty of scope in tracing the variations of ^{53}Mn itself during the past hundred thousand years or so by analysing deep ice cores from polar ice sheets.

Vegetational change in an aboriginal environment

from Peter D. Moore
Plant Ecology Correspondent

EVER since Iversen (*Danm. geol. Unders.*, 2R, **66**, 1; 1941) described the influence of Neolithic cultures on the vegetation of Denmark, palaeocologists have been forced to accept the fact that the introduction of agricultural practices in north-west Europe (perhaps 3,500 radiocarbon years BP for the British Isles) profoundly altered the contemporary environment. More recent work has suggested that many of the vegetational changes which were once thought to be climatically determined must now be regarded as anthropogenic, for example the decline in lime (*Tilia*) in Britain (Turner, *New Phytol.*, **61**, 328; 1962) and the initiation of blanket peat formation (Moore, *Nature*, **241**, 350; 1973). Some have even considered it possible that pre-agricultural Mesolithic cultures may have modified vegetation on a large scale by using fire to drive game or to favour selectively plant species which provide a source of food such as hazel, *Corylus avellana* (Rawitscher, *Nature*, **156**, 302; 1945). This view has received some indirect support as the result of the recent work of Martin (*Aust. J. Bot.*, **21**, 283; 1973) on the environment of aborigines in the Nullabor region of South Australia.

Martin's interest has centred on the palynological analysis of three radiocarbon-dated cave deposit profiles and their interpretation in the light of modern pollen deposition in the area. Her modern pollen studies have provided a means of recognising past plant communities which, in this arid region, are fairly simple in composition.

The present vegetation of the Nullabor region consists of mallee scrub in the coastal region, which has a slightly higher precipitation (23-25 cm yr^{-1}) than the inland area (16-18 cm yr^{-1}). Temperatures in the two regions are virtually the same, but the number of rain days in the coastal region is roughly twice that experienced inland (80 rather than 30-50 d inland). In the arid interior there is tall, open scrub dominated by *Acacia* and *Myoporum*.

Palynologically the two vegetation types can be separated on the basis of the ratio of Myrtaceae (largely *Eucalyptus* and *Melaleuca*) pollen to that of Chenopodiaceae (many genera including *Atriplex* and *Kochia*). Surface pollen analyses in the arid scrub region consistently showed Myrtaceae : Chenopodiceae (M : C) ratios of less than 0.2. M : C ratios in samples from the less arid mallee scrub zone, on the other hand, were always in excess of 0.5. This simple characteristic of the pollen fallout from the two vegetation types permitted Martin to recognise these communities in the fossil pollen assemblages of the cave deposits.

At one site (Eucla) the M : C ratio increases from a low level at 20,000 BP to a maximum at the present day. Its rate of increase mirrors effectively the postglacial eustatic rise in sea level resulting from the gradual melting of the icecaps. The vegetational change in which arid scrub gives way to mallee can thus be explained by a rise in climatic wetness resulting from the increasing proximity of the coastline.

Two other sites tell a rather different story. They show an increasing abundance of mallee scrub (that is, a higher M : C ratio) until about 4,000 BP when it apparently declined. The date of this decline coincides with an increasing abundance of aboriginal artefacts at these sites. The aborigines of recent times are known to have burned scrub extensively, both for ritualistic purposes and to encourage certain food plants, such as the wild gooseberry. Under the climatic stress of aridity it is quite feasible that repeated burning of the scrub could have reversed the trend in vegetational development caused by ameliorating climate and have produced an anthropogenic plagioclimax of arid scrub. This seems to be one of the best documented examples of the influence of a pre-domestication human culture on the course of vegetational development in a wide geographic region.

Nature Vol. 249 May 10 1974

European tumour virology at Aviemore

from Elizabeth Rogers

THE momentum of tumour virus research is such that pauses for breath are essential if one is not to be left gasping behind. So it was that an informal meeting of European tumour virologists at Aviemore, Inverness-shire from April 3–5 provided an opportunity for gathering together the threads of recent progress. The meeting was organised by Professor J. Subak-Sharpe (Institute of Virology, Glasgow) and the sixty or so short contributions covered research into all major groups of tumour viruses. Outstanding were the descriptions of the use of restriction enzymes as tools for analysing the genomes of DNA viruses, and the use of pieces of DNA as infective agents in order to define, for instance, the size of the transforming 'gene'.

The small DNA papova viruses have, not surprisingly, yielded most rapidly to analysis with restriction endonucleases. Linear SV40 DNA produced by *Escherichia coli* R_1 endonuclease can transform rat embryo kidney cells (P. J. Abrahams, State University, Leiden), although it can no longer cause productive infection in BSC-1 monkey kidney cells. Transforming activity of restriction fragments smaller than the whole genome is being investigated. A new SV40-specific antigen reported by C. de Vaux St Cyr (Institute of Cancer Research Villejuif) will provide food for thought for genome analysers, already overburdened with gene products to fit into too little virus DNA. This antigen—named 'C'—is cytoplasmic and distinct from T antigen in several other respects. Those who think that polyoma might behave like SV40 will be increasingly disillusioned by reports like that of R. Kamen (Imperial Cancer Research Fund, London), who has found that late in polyoma infection, the major virus-specific RNA is a total transcript of the minus strand—unlike the situation in SV40-infected cells. A transcription map of the polyoma genome is now available, derived from analysis of eight fragments formed by *Haemophilus parainfluenzae* endonuclease II (Hpa_{II}). The origin of replication has been localised in fragment 5 by M. Fried and L. Crawford (ICRF, London). There is a small region of homology with SV40 DNA.

Larger DNA viruses are more complex substrates for restriction analysis, but already considerable progress with adenoviruses (Ad) 2 and 5 has been made. Using a combination of Eco_{RI} and Hpa_I restriction enzymes, P. H. Gallimore (Medical School, Birmingham) has analysed the parts of the adenovirus genome which are present in Ad2-transformed cells. In some lines as little as 14% of the genome remains. J. F. Williams (Institute of Virology, Glasgow) also reported that two Ad5-transformed cell lines have, respectively, $2\frac{1}{2}$ and $5\frac{1}{2}$ copies of the left end, representing about 30% and 40% of the genome. These findings relate to the question of how much adenovirus DNA is essential for transformation. F. L. Graham (State University, Leiden) has treated rat embryo cells with sheared adeno-DNA. Ad5-DNA will transform these cells even when only about 1×10^6 daltons in size. If half-molecules of Ad5-DNA are made, the transforming activity can be localised in the GC-rich half, and after restriction with Eco_{RI}, it is further localised in the large A fragment, which includes the left end of the molecule. Considering that transformed cell lines exist which only contain the terminal 12% of the left half of the genome, transforming activity must be confined to this site.

Although the problems presented by herpes and Epstein-Barr viruses seem much more immense, these viruses are slowly yielding to the same methods as have been used successfully with small DNA viruses, and their role in human carcinomas is becoming clearer at the same time. Herpes virus (HSV) is a potential candidate for a human tumour-inducing virus. Patients with different carcinomas have been shown to carry HSV-specific non-virion antigens in their sera, and many studies of the transforming potential of HSV or HSV-DNA are now in progress. For example, infection of human embryonic lung cells with HSV is abortive in certain conditions, and cells can become stably transformed (K. Munk, Institute of Virology, Heidelberg). HSV cannot be rescued by cocultivation, so that this may be a good experimental system for studying latency of HSV in human tissue. Another system has been developed by J. C. M. Macnab and N. M. Wilkie (Institute of Virology, Glasgow), who have obtained focal transformation of rat embryo cells by HSV types 1 and 2, as well as by temperature-sensitive (*ts*) mutants and sheared DNA derived either from wild type or from *ts* mutant viruses. As with adenovirus and SV40 DNAs, infectivity of DNA is far more sensitive to shearing than is transforming activity. Sheared HSV-DNA of $5\text{-}7 \times 10^6$ daltons (whole genome is 100×10^6 daltons) will induce transformation. J. K. McDougall (Medical School, Birmingham) demonstrated by *in situ* hybridisation that among a population of human cervical carcinoma cells, only very few contain detectable amounts of HSV-DNA, which may explain why whole virus cannot be isolated from the carcinoma. *In situ* hybridisation, because it allows detection of viral genomes at a cellular level, provides another dimension in the overall analysis of the biochemistry of tumours.

H. Diggelman (Swiss Institute of Cancer Research, Lausanne), introducing a series of papers on RNA viruses, said that a central problem in understanding the function of RNA tumour viruses is still that of determining whether the 70S RNA genome is polyploid. 70S RNA is not found attached to polysomes, nor even in the first budding virus particles, but is apparently assembled later. J. T. Parsons (University of Zurich) has evidence from fingerprint analysis that the genome size is about 3×10^6 daltons—the size of one subunit. Conclusive proof that avian leukaemic myeloblasts contain at least one complete integrated avian myeloblastosis virus (AMV) genome was provided by H. Ogura (Robert Koch Institute, Berlin) and F. Lacour (Institute Gustave Roussy, Villejuif) who have found that AMV production can be induced after infection of helper factor-negative chick cells with leukaemic myeloblast DNA. Similar results were got with wild type or *ts* mutant Rous sarcoma (RSV)-infected cell DNA. The minimum infective size suggests that the information from one RSV subunit may be sufficient. Viral mutants are necessary additional tools in these experiments. R. R. Friis (Robert Koch Institute, Berlin) has isolated representative mutants of the whole replicative cycle in RSV, including one which does not assemble reverse transcriptase into the virion.

Another aspect of RSV transformation was discussed by A. Vaheri (University of Helsinki), who has found that a type-specific glycoprotein, which is normally an integral part of the chick fibroblast cell membrane, disappears on transformation of the cells by RSV. If a *ts* virus mutant is used, the glycoprotein reappears at the non-permissive temperature. W. F. H. Jarrett (University of Glasgow) has studied the horizontal transmission of feline leukaemia virus (FeLV), and the incidence of leukaemia itself as compared with FeLV antibodies in different cat populations. He concludes that one of the primary events in leukaemia may be immunodepression of the response to FeLV antigens themselves. Significantly, the existence of horizontal transmission may allow the development of anti-FeLV vaccines (see *Nature*, **248**, 230; 1974).

Certainly this meeting served to demonstrate again the increasing finesse of the techniques being used to study tumour viruses. One hopes that probing into the mechanism of transformation in these ways will lead to an understanding of the spontaneous events which produce tumours.

Reversible restoration of the birefringence of cold-treated, isolated mitotic apparatus of surf clam eggs with chick brain tubulin

Mitotic aparatuses have been isolated which can incorporate heterologous tubulin and can assemble this tubulin into birefringent fibres similar to those of mitotic apparatuses of living cells.

Several mechanisms have been proposed to explain the separation of chromosomes by the mitotic apparatus (MA). Suggestions such as generation of a tangential force by the spindle body[1], sliding of microtubules[2,3], reversible polymerisation of spindle fibres[4] or participation of a non-microtubule 'movement factor'[5], possibly actin[6], have arisen from observations on living or fixed intact cells. Such studies suffer from the inability to experiment directly with the MA except as it exists in the complex whole cell. If it were possible to isolate MAs which could separate chromosomes *in vitro* it should be possible to study those processes relevant to the mechanism of chromosome separation and those that are incidental to it. We report here observations on isolated MAs which (a) incorporate added heterologous tubulin and (b) after removal of homologous tubulin, assemble added heterologous tubulin into birefringent fibres similar in distribution to those of MAs in living cells.

Mitotic apparatus isolation

MAs isolated by methods using organic solvents[7,8] differ from MAs in living cells in that their birefringence does not disappear at low temperatures. Recent observations by Weisenberg[9], which demonstrate that calcium ion concentration must be reduced to enable microtubules to be polymerised *in vitro*, suggested that low calcium media be tried in MA isolation procedures. We found that a modification of the microtubule polymerisation mixture described by Weisenberg allows MAs to be isolated from at least eight species of eggs and that the MAs are cold labile, calcium sensitive, stable at room temperature and possess a birefringence approximately equal to that of *in vivo* MAs[10]. The isolation mixture consists of 0.1 M MES[9] or PIPES[11] buffer, *p*H 6.85, 0.25–1 mM $MgCl_2$, 1–5 mM EGTA, 10 mM of a proteolytic enzyme inhibitor, *p*-tosyl arginine methylester HCl (TAME) and Triton X-100 (0.2–1% depending on the species of egg used). Addition of GTP (1 mM), which is essential for the *in vitro* polymerisation of microtubules[9,11], is not required for MA isolation but was included in all reassembly experiments described below. TAME could be eliminated from the isolation mixture but MAs were then obtained in poor yield and were fragmented and irregular in shape. We report experiments using MAs from eggs of the surf clam *Spisula solidissima*.

Eggs of the clam were obtained and handled as previously described[12,13] and were parthenogenetically activated with KCl. Fully formed first meiotic MAs at metaphase were uniformly present by 12–14 min after activation[12]. Vitelline membranes were removed with 1 M glycerol solutions[14] and the eggs were immediately suspended in 2–3 times their volume of isolation medium with Triton X-100 at room temperature. The eggs were then dispersed by agitation with a Vortex mixer and the MAs collected by centrifugation at 400–500*g* for 1.5–2 min at room temperature. The MAs were then resuspended in at least five times their volume of isolation medium without Triton X-100 (Fig. 1*a*). Measurements of the birefringence of the isolated MAs were made with a Zeiss polarisation microscope (Photomicroscope II) equipped with a Brace-Koehler compensator and a potentiometric device for automatic recording of compensator angle.

Chick brain tubulin was routinely isolated by homogenising the brains of 1–3-d-old chicks in a volume of polymerising solution (1 mM EGTA, 1 mM GTP, 1–2 mM, $MgCl_2$, 0.1 M PIPES buffer, *p*H 6.9) equal to 1.5 times the wet weight of the brains. The homogenate was centrifuged for 1 h at 28,000*g* at 4° C. The supernatant was then incubated at 37° C for 45 min until it became very viscous as a result of the forma-

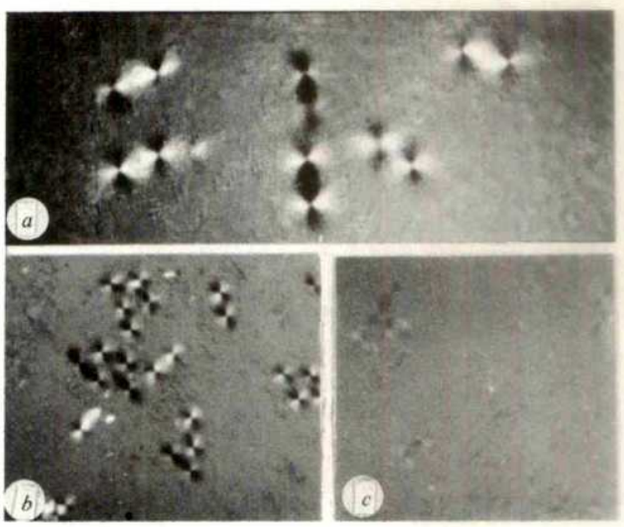

Fig. 1 *a*, Isolated MAs of *Spisula* eggs at metaphase in isolation medium. Distance between astral centres averages 22 μm. ×2,500. *b*, Isolated MAs in isolation medium to be compared with the same preparation cooled to 4° C for 20 min. *c*, Considerable decrease in birefringence is visible and on measurement amounts to one-quarter to one-half the birefringence originally present. ×1,000.

TABLE 1 Spisula mitotic apparatus isolated at metaphase at 22–24° C

Treatment of MAs		Retardation*	% of control retardation
Control	Normal MAs in isolation mix at 25° C	2.70 μm	100%
	Normal MAs in isolation mix at 4° C for 15 min	1.25 μm	46%
Tubulin	MAs in tubulin (9 mg ml^{-1}) at 25° C for 15 min	3.70 μm	137%
	MAs in tubulin (9 mg ml^{-1}) at 4° C for 20 min	1.10 μm	41%
	MAs from above, removed from cold and incubated at 30° C for 15 min	2.40 μm	90%

* Each retardation is based on 10–13 measurements. The tubulin was purified from chick brain

tion of microtubules. The microtubules were collected from the supernatant by centrifugation at 28,000*g* for 15 min at 25° C. The sediment of microtubules was resuspended in an amount of polymerising solution equal to one-third to one-quarter the volume of the original supernatant and placed on ice for 30 min to depolymerise the microtubules. This preparation was centrifuged at 105,000*g* for 1 h to remove any remaining intact microtubules. The supernatant which contained the tubulin subunits was either used immediately for polymerisation with the isolated MAs or, in some experiments, was further purified by one or two additional cycles of polymerisation and depolymerisation. Tubulin from chick brain was used rather than tubulin from *Spisula* eggs because it was much easier to obtain in large amounts, and other work had recently shown that heterologous systems of chick brain tubulin and sea urchin flagellar axonemes could copolymerise[15].

Birefringence

The rapidity with which cold treatment reduced the birefringence of isolated MAs was strongly dependent on the time between MA isolation and immersion in a cold bath.

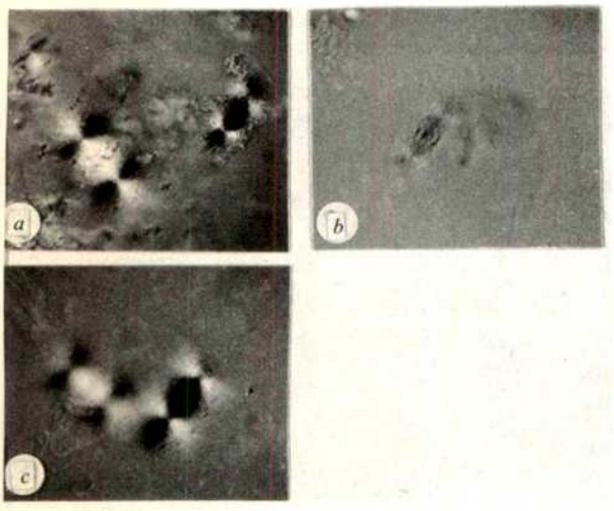

FIG. 2 *a*, MAs were isolated and incubated in concentrated tubulin solutions at room temperature for 30 min. They were then centrifuged out of tubulin, washed in isolation medium and mixed with intact MAs from the original isolation which had remained in isolation medium at room temperature. The difference in size is readily apparent and is uniform. ×2,500. *b*, The MA remnant results from cooling in tubulin and should be compared with the original MAs in tubulin at room temperature. *c* was taken several minutes after suspension of intact MAs in tubulin and significant growth had already occurred. ×2,500.

MAs cooled to 0–4° C within 1 min of isolation completely disappeared and were not visible in the polarisation microscope. Those treated 5–6 min after isolation required only 10–15 min at low temperature to reduce their birefringence to a constant level about one-quarter to one-half that of normal, (Table 1 and Fig. 1*b* and *c*) whereas if greater than 15 min elapsed between isolation and cooling, reduction of birefringence was delayed for several hours. In the latter cases a remnant survived which had the form of an MA with considerably reduced birefringence[10]. Electron microscopic observations showed that microtubules were absent from cold-treated MAs with reduced birefringence but that such MAs contained chains of ribosome-like particles aggregated with some amorphous material[10]: it is this material which presumably gives rise to the residual form birefringence of the MA remnant[16,17] (Fig. 1*c*). The MAs depleted of tubules still contained the chromosomes and the mitotic poles (centrosomes).

Tubulin assembly

Intact MAs to be resuspended in brain tubulin were obtained in isolation medium, centrifuged once at low speed and then resuspended in IM plus tubulin at the desired concentration. This procedure, which diluted the Triton X-100 concentration to less than 0.1% and reduced the concentration of free clam tubulin subunits, took 5–6 min. Such suspensions of intact MAs, in solutions containing up to 10 mg ml^{-1} chick brain tubulin (approximately the concentration of tubulin in intact eggs[18,19]), in contrast to MAs suspended in isolation medium alone, retained their cold lability for at least 1 h. If these intact MAs were kept at room temperature in tubulin they increased their birefringence over 15 min (Table 1) with little observable change in shape. At greater concentrations of tubulin (15–20 mg ml^{-1}) the MAs became considerably wider at the equator, the length of the astral fibres increased and the distance between astral centres increased by up to 40% (Fig. 2*a*). These results show that chick brain tubulin can assemble into clam MAs which still contain clam microtubules.

Perhaps the most interesting observations in these studies concern the return of birefringence in MAs which were depleted of their own microtubules by cold treatment and were then warmed to 30° C in the presence of chick brain tubulin. In these experiments, the isolated MAs were sedimented from isolation medium and then resuspended in isolation medium + tubulin (9 mg ml^{-1}). Control MAs were suspended either in isolation medium alone or in isolation medium with tubulin and 10^{-3} M colchicine. The MAs were then cooled to 4° C for 15 min and the birefringence was reduced by about 60% (Fig. 2*b* and *c* and Table 1). When cold-treated MAs were incubated at 30° C the birefringence in the preparations which contained isolation medium and tubulin partially returned in 15 min, (Table 1) and within 0.5–0.75 h the birefringence had returned to the level seen before cold treatment. Moreover, these MAs continued to increase in size and after 2 h at 30° C many were three to four times as long as the normal MAs (Fig. 3*a* to *d*). Control MAs in the presence of isolation medium alone or which contained colchicine in addition to the tubulin showed no restoration of normal birefringence when warmed from 4° C to 30° C. Reassembled MAs could be cold depolymerised after periods of up to 2 h and on addition of fresh GTP and rewarming to 30° C birefringence returned to the cold-treated remnant although such doubly-restored MAs were generally less birefringent than those restored once. The doubly restored MAs were still cold labile. Restored MAs could be spun out of tubulin solutions and suspended in isolation medium alone, in which they were stable at room temperature. Thus, restored MAs, resembling those isolated directly in isolation medium, are stable to dilution of the tubulin subunits in which they were for-

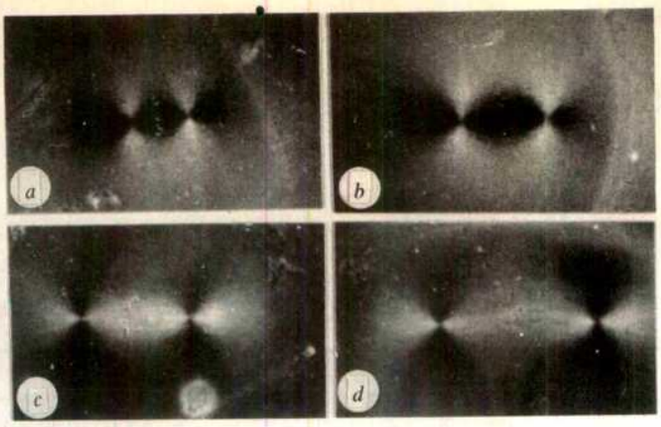

FIG. 3 *a*, Example of a MA depleted of tubules incubated in tubulin at 30° C. for 30 min. Compare with the MAs in Fig. 2*b* and *c*. Note the metaphase chromosomes. ×2,500. *b–d*, MAs from the same preparation as in (*a*) but incubated for 1 h (*b*) or 1.5 h (*c* and *d*). The length of the MA in *d* is approximately 3.5 times normal (compare Fig. 2*c*). At least half of the reconstructed MAs in the preparation attained lengths about that of the MA in *c*. ×2,500.

merly bathed. The birefringence of restored MAs is removed by 10^{-3} M calcium but is stable in 10^{-5} M calcium. This range of calcuim concentration would be expected from *in vitro* observations on neurotubule polymerisation where microtubule assembly can take place and the microtubules remain stable in 10^{-4} M but disappear at 10^{-3} M calcium. These results show that brain tubulin can reversibly assemble into clam MAs which have been depleted of their own microtubules by cold and that such reassembled MAs are cold labile, calcium sensitive, stable to dilution and capable of considerable increase in overall length.

Attempts were made to follow the reformation of birefringent fibres in the MA remnants. Birefringence appeared to return throughout the MA rather than at any focal point. Similarly, during cold treatment, birefringence is lost all along the MA which does not shorten in length. Since *in vivo* MAs decrease in length as well as birefringence on being slowly cooled to low temperature[4] the question of the behaviour of the isolated MAs compared with those *in situ* may be raised. *In vivo Lytechinus* MAs at first cleavage, however, lose birefringence simultaneously along the whole MA when cooled rapidly with large temperature jumps and restore birefringence uniformly along the MA when the eggs are returned to the original temperature[20]. This behaviour more nearly resembles our results of restoration of birefringence in cold-depleted MAs.

It is important to note that MAs isolated by our techniques increase in length but do not shorten and that they are

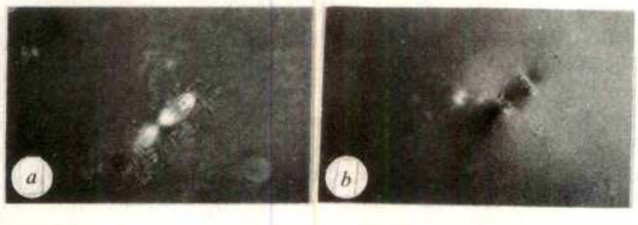

FIG. 4 *a*, MA at anaphase in isolation medium. ×2,500. *b*, Regrown MA from an anaphase preparation after cold treatment. Chromosomes appear to cluster about the astral centres. Although numerous anaphases were present in the original preparation (as well as metaphase MAs) after about 1 h at 30° C only metaphase and 'telophase' configurations could be seen. The birefringence of the region between chromosome clusters in the latter is lower than that in chromosome–pole regions of metaphase MAs in the same preparations. ×2,500.

stable to dilution of tubulin. This indicates that they can incorporate tubulin but that they can not disassemble it easily once it is integrated. Since disassembly as well as assembly is an important part of the process of chromosome separation[4] and it did not seem to occur in the metaphase MAs, we attempted to isolate MAs at anaphase. This proved difficult because of the very short anaphase time in *Spisula* and because such MAs were considerably more fragile than metaphase MAs and tended to fragment. Nevertheless, some anaphase MAs were obtained (Fig. 4*a*) whose birefringence was cold labile and could be restored when incubated in tubulin solutions. In some cases, cold depleted anaphase MAs incubated in tubulin for about 1 h attained a configuration resembling very late anaphase or early telophase, (Fig. 4*b*) with chromosomes at the centres of quite small asters. Details of how this configuration was achieved are now being investigated.

We have described a technique for isolating MAs which can incorporate heterologous tubulin into the existing intact MA and which, after depletion of native microtubules by cold treatment, can utilize added tubulin to reconstruct the birefringent material[15,16,18,21] in approximately normal distribution. Such MAs continue to grow in tubulin solutions at room temperature or above and can grow considerably longer than normal. The ability to incorporate exogenous tubulin is at least one of the functions of the *in vivo* MA and is part of the process of chromosome separation. Whether our results with anaphase MAs are due to disassembly of microtubules from the isolated MAs is not clear but it may now be possible with proper modification of the medium and variation of tubulin concentration to obtain chromosome separation *in vitro* in mass-isolated MAs.

Similar experiments have been carried out recently in other laboratories in which observations have been made on MAs of single cells perfused with tubulin solutions[22,23].

These studies were supported by National Science Foundation grants to L. I. Rebhun and J. L. Rosenbaum and a National Institutes of Health training grant (Fertilization and Gamete training program) to the Marine Biological Laboratory. The experiments were carried out at the Marine Biological Laboratory, Woods Hole, Massachusetts.

Roles for *E. coli* DNA polymerases I, II, and III in DNA replication

Robert C. Tait* & Douglas W. Smith

Department of Biology, University of California, San Diego, La Jolla, California 92037

Chain elongation during E. coli *DNA replication proceeds in three distinct stages. Participatory roles of the three* E. coli *DNA polymerases in each of these stages has been determined.*

ALTHOUGH the overall process of DNA chain elongation during DNA replication is semiconservative[1], the biochemical events involved are unknown[2]. *E. coli* DNA polymerase I (PolI) cannot catalyse *in vitro* DNA synthesis in a semiconservative manner using isolated DNA as a template[3]. *E. coli polA* mutants[4], deficient in PolI, grow normally, suggesting that PolI is not an essential enzyme. *PolA* mutants have been used to purify further DNA polymerising enzymes including DNA polymerase II (PolII) and DNA polymerase III (PolIII)[5–8]. *E. coli polB* mutants[9,10] deficient in PolII, and *dnaE* mutants[11,12], deficient in PolIII, have been isolated and studied. *PolB* mutants are similar phenotypically to their *polB*$^+$ parental strains, although differences in DNA repair ability have been detected[13,14]. In contrast, only thermosensitive *dnaE* mutants have been isolated, suggesting that PolIII is an essential enzyme.

PolI preferentially catalyses a 'repair' polymerisation reaction *in vitro*: conversion of partially single-stranded DNA (ssDNA) into the double-helical species. Although optimal reaction conditions are different, the polymerisation reactions catalysed by purified PolII and PolIII *in vitro* are also substantially 'repair' reactions[7,15].

In the work reported here, the physiological roles of the three known *E. coli* DNA polymerases in DNA replication were examined. The temporal fate of newly replicated DNA obtained from *E. coli* mutants deficient in one or more of these DNA polymerases was analysed using alkaline sucrose gradients. Results indicate that PolIII is essential for one elongation step and involved, if not essential, in a second, that PolI is involved but not essential for a third elongation step, and that PolII is needed and involved only in the absence of one or both of the other two enzymes (Fig. 4).

Pol I

SsDNA, labelled for 1 min in W3110 *polA*$^+$ cells, sedimented in a broad band when synthesised at both 30° C (Fig. 1*a*) and 43° C (Fig. 1*c*). The sedimentation values (30S to 110S) corresponded with molecular weights intermediate to parental sized 120S to 130S ssDNA and the short newly synthesised 15S to 20S ssDNA fragments[16]. In contrast, 1-min-labelled ssDNA from p3478 *polA1* cells[4], deficient in polI (0.5%–2% W3110 activity[19]), sedimented more slowly (Fig. 1*b* and *d*) when synthesised either at 30° C (10S to 40S) or at 43° C (15S to 50S). During subsequent DNA synthesis in both strains (10 min and 40 min cold chase profiles), the short DNA pieces were converted first into intermediate sized pieces and then into large pieces, at a rate somewhat slower at 30° C than at 43° C. The rate of conversion was slower in p3478 than in W3110, both at 30° C and at 43° C, in agreement with earlier observations[17,18]. Thus, PolI is required for rapid conversion of newly synthesised DNA into intermediate sized pieces. The residual slow rate observed in p3478 may be due to residual PolI activity[19] or to attempts by another DNA polymerase to substitute for PolI.

* Present address: Department of Biochemistry and Biophysics, University of California, San Francisco, San Francisco, California 94122

Pol III

E. coli E486 *dnaE*486 is a temperature-sensitive *E. coli* mutant[11] with normal PolI and PolII activities and no detectable PolIII activity *in vitro* at either 30° C or 43° C[20]. The sedimentation profiles (Fig. 2*a*) of ssDNA synthesised by E486 at 30° C are similar to those of ssDNA from W3110 cells (Fig. 1*a*). The increased relative amount of slowly sedimenting DNA synthesised for 1 min in E486 suggests that PolIII is partially defective *in vivo* in E486 at 30° C, as *in vitro*[20].

The sedimentation profiles of DNA synthesised at 43° C by E486, however, are strikingly different (Fig. 2*b*). DNA synthesis in E486 was greatly reduced at 43° C and occurred mainly within the first minute after shift to 43° C. Most of the DNA synthesised for 1 min or 3 min sedimented slowly (20S or less). During the subsequent 7 min and 37 min cold chase, about half of the labelled DNA was converted slowly into intermediate sized pieces, with some DNA degradation. Even after 40 min of synthesis at 43° C, however, about half of the initially synthesised DNA continued to sediment slowly. Much slowly sedimenting ssDNA remained even after 80 min synthesis at 43° C (not shown). Thus, PolIII is required for the complete conversion of short DNA pieces into intermediate sized pieces, and, when PolIII is defective, the rate of synthesis, or processing, of these short pieces is greatly reduced. The slow rate of the observed partial conversion may have been due to residual *in vivo* PolIII activity at 43° C or to an attempt by another DNA polymerase to catalyse this synthesis. Further, nearly all the ssDNA sedimenting more rapidly than about 20S was found as intermediate sized 70S to 120S pieces, even after 80 min of synthesised and/or processed, they were converted rapidly version of intermediate sized into parental sized pieces.

Very little DNA was found at any time in the region 30S to 70S, suggesting that once the 20S short pieces were fully synthesized and/or processed, they were converted rapidly into 70S to 120S intermediate sized pieces. Figure 1 shows that PolI, when present, was responsible for the rapid conversion. This role of PolI in the synthesis of the intermediate sized pieces was further examined using *E. coli* E4862, a *polA1* derivative[20] of E486. Sedimentation profiles of DNA synthesised by E4862 at either 30° C or at 43° C (Fig. 2*c*) are identical to those from E486, except that a substantial fraction of the 10 min and 40 min ssDNA from E4862 sedimented as 30S–70S material. Thus, when PolI activity was greatly reduced, processed short DNA pieces were converted slowly into 70S to 120S pieces, whereas in the presence of wild-type PolI activity, this conversion occurred sufficiently rapidly that very little 30S to 70S DNA was observed.

The slow conversion of short DNA pieces into intermediate

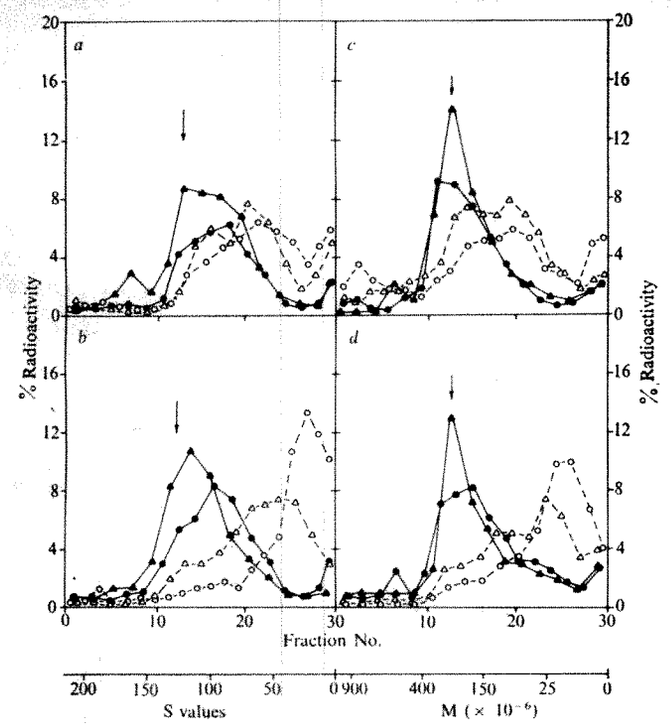

FIG. 1 Alkaline sucrose gradients of DNA from W3110 and p3478. *E. coli* W3110 *thy*⁻ and p3478 *thy*⁻ *polA1* were grown in a Tris–glucose–minimal salts (TG_0) medium containing 0.1% casamino acids and ^{14}C-thymine (2 μCi ml^{-1}, 2 μg ml^{-1}) at 30° C to 2 × 10^8 cells ml^{-1}. Half of each culture was collected by centrifugation (4° C, 5 min, 10,000 *g*), resuspended in an equal volume of TG_0 minus glucose, and added to a supplement containing ^{3}H-thymidine, to give 6 μCi ml^{-1}, and glucose, casamino acids and thymine in amounts to yield TG_0 plus 0.1% casamino acids. The cultures were incubated at 30° C with aeration. After 1 min and 3 min, quarter volume samples were frozen immediately in dry ice–acetone. At 3 min, non-radioactive thymidine to 50 μg ml^{-1} was added. At 10 min and 40 min, two further quarter volume samples were frozen immediately. The remaining halves of each of the two original cultures were shifted to 43° C for 15 min, collected by centrifugation (4° C, 5 min, 10,000 *g*), resuspended in prewarmed TG_0 minus glucose, added to supplement, and incubated at 43° C with aeration. Samples were frozen at the four time points, and the cultures were chased with non-radioactive thymidine, as described above. 43° C was attained within 30 s after cultures were placed at 43° C. A 1 ml sample of each frozen cell suspension was thawed, the cells were converted into lysozyme–EDTA spheroplasts, and ≤5 × 10^7 cells (50 μl of each sample) were lysed by layering gently into 0.1 ml 0.5 N NaOH over a 4.7 ml alkaline sucrose gradient (5%–20% linear gradient in 0.1 N NaOH), using the procedures of Smith and Meun[35]. Following centrifugation (30,000 r.p.m., 15° C, 105 min, Spinco SW50.1 rotor), fractions were collected directly onto Whatman 3 MM paper squares. These were dried, washed twice in cold 5% Cl_3 CCOOH, twice in 95% ethanol, once in acetone, dried, and assayed for radioactivity. The total radioactivity layered on each gradient was 7,000–35,000 c.p.m. for ^{3}H and 500–1000 c.p.m. for ^{14}C. Sedimentation coefficients and molecular weights were determined using known relations [36,37] and phage T4 DNA as a standard. ^{14}C-DNA sedimentation profiles were similar in each gradient and nearly identical to the 40 min ^{3}H-DNA profiles; the peak of the ^{14}C-DNA is indicated by the arrow. *a*, W3110 *polA*$^+$, 30° C; *b*, p3478 *polA1*, 30° C; *c*, W3110 *polA*$^+$, 30° C; *d*, p3478 *polA1*, 43° C. ○, 1 min ^{3}H-DNA; △, 3 min ^{3}H-DNA; ●, 10 min ^{3}H-DNA; ▲, 40 min ^{3}H-DNA.

sized pieces observed in E4862 at 43° C (Fig. 2*c*) may involve participation of PolII, as E4862 is deficient in PolI and PolIII at 43° C, although residual PolI and/or PolIII activity *in vivo* at 43° C is possible. We examined these possibilities further using an independent *dnaE* mutant, *E. coli* BT1026 *polA1 dnaE*1026. BT1026 possesses greatly reduced PolI activity, normal PolII activity, little detectable PolIII activity (<1% wild type) at 42° C, and reduced PolIII activity (<10% wild type) at 30° C *in vitro*[19,20,21]. Although sedimentation profiles of DNA synthesised by

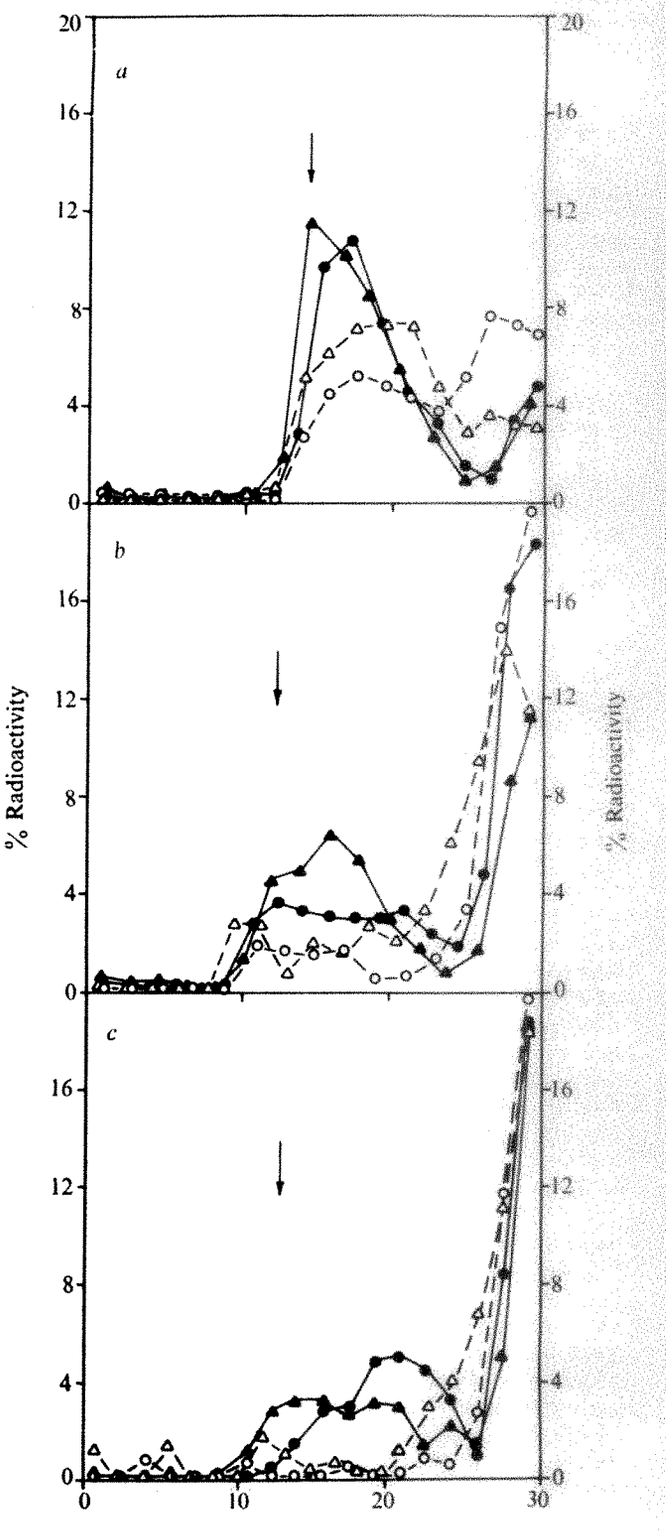

FIG. 2 Alkaline sucrose gradients of DNA from E486 and E4862. *E. coli* E486 *thr–leu–thi–thy–lac–met–dnaE*486 and E4862 *arg–his–thy–polA1 dnaE*486 were separately cultured and the DNA was labelled and analysed as described in the legend to Fig. 1. E4862 *thy*⁻ was obtained from E4862 *thy*$^+$ using trimethoprim selection[38]. The types of curves are as in Fig 1; the ^{14}C-DNA profiles were similar to the 40 min ^{3}H-DNA profile in (*a*) in each case, with the peak indicated by the arrow. The total radioactivity was 900–13,000 c.p.m. for ^{3}H, and 1,000–5,000 c.p.m. for ^{14}C. *a*, E486 *polA*$^+$ *dnaE*486, 30° C; *b*, E486 *polA*$^+$ *dnaE*486, 43° C; *c*, E4862 *polA1* *dnaE*486, 43° C.

BT1026 at 30° C (Fig. 3*a*) are similar to those of p3478 (Fig. 1*b*) as expected, much of the ssDNA from BT1026 sedimented slowly even after the 37 min chase. These features suggest that PolIII in BT1026 is also partially defective at 30° C *in vivo*, as *in vitro*[20], but to an even greater extent than in E4862. The above sedimentation properties of the DNA synthesised by BT1026 at 43° C were considerably accentuated (Fig. 3*b*). The amount of DNA synthesised was reduced greatly, and some degradation occurred in time. Most of the DNA sedimented slowly even after a 37 min chase and the larger pieces sedimented as intermediate sized pieces. Since these sedimentation properties are similar to those of ssDNA from the independent *dnaE* mutant E4862 (Fig. 2*c*), residual PolIII activity at 43° C probably was not involved in the slow conversion of short DNA pieces into intermediate sized pieces.

A less complete conversion by BT1026 of short DNA pieces into intermediate sized pieces occurred at 43° C than at 30° C (compare Fig. 3*a* and *b*), suggesting that PolIII, when PolI activity is reduced, participates in this conversion process. This possible role for PolIII is obscured, however, by the requirement for PolIII in the maturation of the short DNA pieces.

Pol II

A role for PolII in this slow conversion was examined using a mutant of BT1026 deficient in PolII. This mutant, H10265, has no detectable PolII activity at 43° C and very little (<0.02% wild type) PolII activity at 30° C[10]. The amount of DNA synthesised by H10265 is similar to that by BT1026 at 30° C. However, two differences in the ssDNA sedimentation profiles are apparent. First, the rate at which short ssDNA pieces were converted into intermediate sized pieces was reduced in H10265 (3 min DNA distributions, Fig. 3*a* and *c*). This suggests that, when PolI is deficient, PolII participates in the conversion of short 20S ssDNA fragments into larger 70S to 120S pieces. Second, the 40 min DNA from H10265 sedimented as rapidly as did the parental DNA. Since PolIII seemed to be partially defective *in vivo* in BT1026 at 30° C (Fig. 3*a*), the presence of PolII, when PolIII is partially defective, apparently prevents conversion of 70-120S DNA into the size and/or shape typical of parental ssDNA. Very little DNA synthesis was observed in H10265 at 43° C; the resulting sedimentation profiles were similar to those of BT1026 at 43° C (Fig. 3*b*).

Further evidence supporting these proposed roles for PolII in DNA replication was obtained in similar studies using *E. coli* HMS83, PolB derivative of p3478 containing no detectable PolI activity *in vitro*[9]. First, the rate of conversion of short ssDNA pieces in HMS83 to intermediate sized pieces was reduced when compared with p3478 (data not shown), again suggesting that PolII, when PolI activity is reduced, participates in this conversion. The slow residual conversion observed in HMS83 was probably due either to residual PolI activity[19] or to PolIII activity. Second, intermediate sized pieces were converted into parental sized ssDNA within 40 min at 30° C, indicating that neither PolI nor PolII were required for this conversion when PolIII was present at wild type levels.

Three stages in chain elongation

Our results can be summarised in the schematic model shown in Fig. 4. Three stages in DNA chain elongation are visualised. In the first stage, synthesis of a short DNA fragment is initiated, the fragment is elongated to a 20S piece, and processed into a form ready for further elongation. These pieces are the short DNA pieces discovered by Okazaki *et al.*[16] When PolIII is deficient, synthesis of these pieces and/or their maturation proceeds very slowly and incompletely. In the second stage, the 20S pieces are converted into intermediate sized 70S to 120S pieces. This conversion proceeds very rapidly when PolI is present in the cell compared with the first stage of chain elongation. When PolI is deficient, both PolII and PolIII can participate in this conversion. In

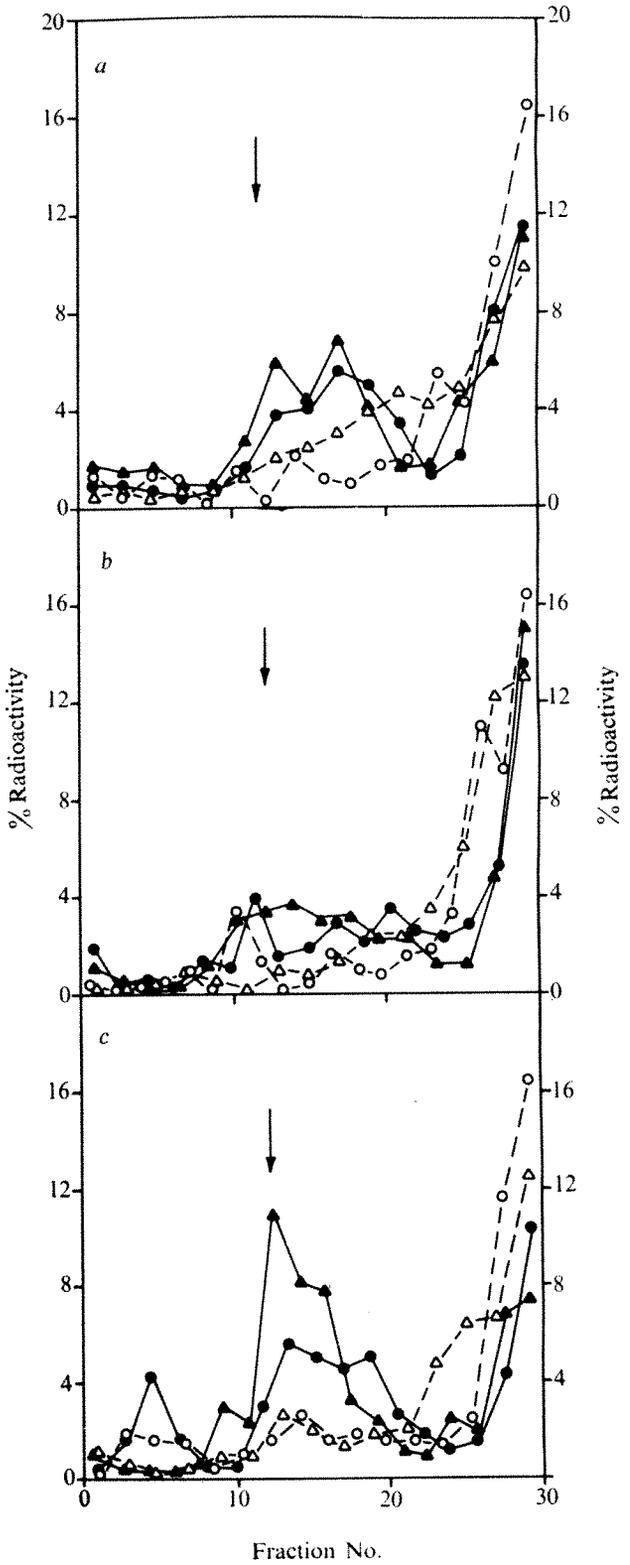

FIG. 3 Alkaline sucrose gradients of DNA from BT1026 and H10265. *E. coli* BT1026 *thy endA polA1*, *dnaE*1026 and H10265 *thy endA polA1 polB*⁻ *dnaE*1026 were cultured separately and the DNA was labelled and analysed as described in the legend to Fig. 1. The types of curves are as in Fig. 1; the ^{14}C-DNA profiles were similar to the 40 min ^{3}H-DNA profile in (*c*) in each case, with the peak indicated by the arrow. The total radioactivity was 500–2,000 c.p.m. for ^{3}H, and 900–5,000 c.p.m. for ^{14}C. *a*, BT1026 *polA1 dnaE*1026, 30° C; *b*, BT1026 *polA1 dnaE*1926, 43° C; *c*, H10265 *polA1 polB*⁻ *dnaE*1026, 30° C.

the third stage, intermediate sized pieces are converted into parental sized pieces. In cells containing PolII, PolIII is required for this process. However, when PolII is deficient in a cell containing a defective PolIII, the conversion seems to take place.

Although biochemical reactions could not be determined in our experiments, the following possibilities seem worth mentioning. PolIII is required for elongation and complete synthesis of the most newly synthesised Okazaki DNA pieces. The RNA found covalently attached to these pieces[22] may serve as a primer for initiation of synthesis of these short pieces, permitting a subsequent elongation reaction similar to the preferred gap-filling reaction catalysed *in vitro* by PolIII[15,23]. This elongation could continue until a termination signal were reached, such as running into the adjacent short DNA piece, terminating stage I.

To begin stage II, the products of stage I may need to be processed. Attainment of a fixed size may suffice. Alternatively, removal of the putative RNA primer may be involved. A subsequent rapid repair of the gap left by the excised RNA, coupled with a ligase joining of the individual short pieces, could result in the 70S to 120S pieces. Since this conversion occurs very rapidly in cells containing PolI, PolI may serve as an RNase H[24], catalysing the exonucleolytic removal of the RNA from the RNA–DNA duplex. Although *E. coli* contains a distinct RNase H activity[25], PolI possesses RNase H activity *in vitro*[26] and seems to have an RNase H role *in vivo* during colE1 DNA replication[27]. When PolI activity is substantially reduced, either PolII or PolIII, or both, may possess RNase H activity and remove the RNA primer. Alternatively, the *E. coli* RNase H may remove the RNA, and PolII and/or PolIII may fill in the gap left by the excised ribonucleotides. Joining of these matured short DNA pieces by a ligase would yield the 70S to 120S pieces.

In stage III, the intermediate sized pieces (50–250 × 10^6 daltons) are converted into parental sized pieces. For a chromosome of 2,500 × 10^6 daltons, 5 to 25 such pieces would exist per chromosome. As an appealing hypothesis, the products of stage II may correspond to the newly synthesized DNA strands of the 12 to 80 loops found in the *E. coli* folded chromosome[28] by Worcel and Burgi[29]. Stage III would then comprise the biochemical events joining these loops together to yield the supercoiled folded bacterial chromosome[29]. This hypothesis also provides a rationale for involvement of PolIII in stages I and III. Considerable indirect evidence for a replication site on the bacterial cell surface has accumulated[30–34], and PolIII seems to prefer a hydrophobic environment[15,21]. Worcel and Burgi[29] propose that the 12 to 80 loops may emanate from an RNA core, since RNA is essential for the integrity of the folded chromosome[28]. Such an RNA core could be part of the DNA replication site at the cell surface. Stage I could then take place in the hydrophobic environment of the DNA replication site, with PolIII as the primary DNA replicase, whereas stage II might not require this environment and/or site and could occur in the cytoplasm. Stage III could then again occur at the replication site, as the Worcell–Burgi loops projecting into the cytoplasm from the replication site were joined together. This hypothesis would then partially compartmentalise the *E. coli* DNA polymerases, localising PolIII to the hydrophobic environment of the cell surface, thus in part explaining the need for different DNA polymerase enzymes to catalyse similar gap-filling polymerisation reactions.

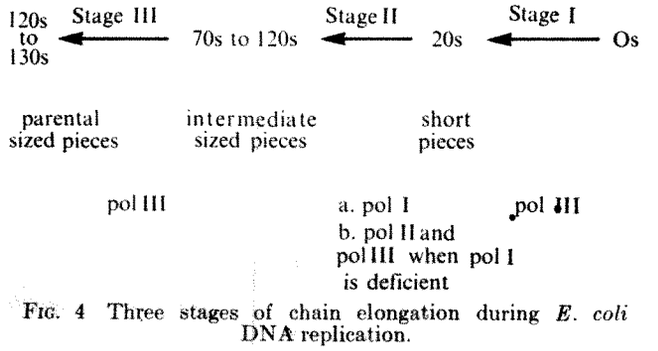

FIG. 4 Three stages of chain elongation during *E. coli* DNA replication.

Barbed bone points, typical of those from the early Holocene settlement of "Early Khartoum", have been found at three sites along the White Nile, south of Khartoum. The form of the fragments and the stratigraphy of the sites throw light on the environment and technology of the early settlements along this part of the Nile.

During archaeological and geomorphological fieldwork along the White Nile south of Khartoum in February, 1973 (see Fig. 1), we found at three sites, fragments of barbed bone points typical of those from the early Holocene settlement of "Early Khartoum"[1]. No radiocarbon dates exist for the "Early Khartoum" settlement, but at El Qoz[2] the characteristic pottery is found stratified below that associated with the Neolithic settlement at Esh Shaheinab, the average date of which is 5,253 ± 415 yr BP (ref. 2, page 107). One of our discoveries, from near the village of Tagra, is of particular interest because it came from a depth of 1.3 m in a soil pit for which two radiocarbon dates are already available. A second discovery was made on an ancient point bar of the White Nile, in swamps opposite Esh Shawal near Guli. The third site, which we studied in some detail, was located at Shabona and yielded an industry identical to that from "Early Khartoum". Shabona is a settlement site and only the second with this cultural pattern to have been found and excavated. A similar site was located about 3 km distant from Shabona so that it seems likely that other similar riverside settlements would be found in this part of the White Nile between Khartoum and Kosti.

Tagra site

Williams[3] in 1963 collected subfossil freshwater and amphibious Mollusca from 1.6 to 1.9 m depth in a soil pit near Tagra, the shell giving a radiocarbon date of 8,370 ± 350 yr BP (Isotopes Inc. 1485, dated by courtesy of Professor A. J. Whiteman). This pit was resampled by Williams and Adamson in 1972 and a shell radiocarbon date of 8,130 ± 225 yr BP (Sydney University Radiocarbon Laboratory SUA-68) was obtained from a depth of between 1.2 to 1.4 m. In February 1973, Adamson extended and sampled this pit yet again for more shell material and found, at a depth of 1.3 m, two fragments of a barbed bone point, fragments of small bones of mammal, fish bones including cat fish spines, and shells of *Pila wernei* (Philippi) and *Lanistes carinatus* (Oliver). The presence of large complete *Pila* up to 9 cm long suggests deposition of the shells and bone *in situ* and lack of disturbance by soil cracking and mixing.

The location and stratigraphy of the Tagra pit are shown in Fig. 1. The pit is located 230 m on a 42° bearing from the steel beacon marking the surveyed position of 13°56′N, 32°22′E and it lies about 0.5 km east of the present 377.8 m high level of the White Nile as controlled by the Jebel Aulia dam. The pit surface is between 378.2 and 378.6 m which is somewhat lower than the elevation first reported[4]. Before the dam was built, local mean low water level was 372.2 m and local mean flood level was 375.4 m at the nearby Ed Dueim gauge[5]. The pit surface is, therefore, about 6 m above the former low level, about 3 m above the former high level and about 0.4 to 0.9 m above the present high water level caused by the Jebel Aulia dam.

The barbed point fragments, other bones and shells just mentioned, occurred near the base of a dark-grey clay 1.5 m thick, which overlies a calcic layer 10 cm thick (1.5 to 1.6 m) containing abundant hard calcium carbonate nodules and softer calcareous aggregates embedded in fine sand and silt. Beneath the calcic layer is 15 cm of olive-grey finely laminated silts (1.6 to 1.75 m) with thin bands of reddish-yellow limonite accentuating the bedding planes. From 1.75 to 1.9 m, very pale greyish-brown clayey sand contains occasional shells of *Pila wernei* and *Melanoides tuberculata* (Müller). From 1.9 to 2.05 m there are alternating bands of rippled brown clay and grey or yellow sand, each band being about 0.5 to 1.0 cm thick. Occasional strongly calcareous lenses occur in this horizon. The shells for the 8,370 ± 350 yr BP date came from between 1.6 and 1.9 m and were *in situ*. Light olive-grey clayey sand from 2.05 to 2.20 m formed a transitional layer above light grey fine quartz sand at least 60 cm thick. The total depth examined was 2.85 m.

Sequence of events at Tagra

A tentative interpretation of the sequence of events at this site is offered. Fluviatile fine sands and clayey sands were laid down in the White Nile up to at least 376 m, that is about 4 m above the normal minimum water level before the Jebel Aulia dam was built. A further 30 cm of fluviatile aggradation occurred and both aquatic and semi-aquatic molluscan shells were incorporated in the silts, clays and sands some 8,000 to 8,500 yr ago at an elevation at least 0.5 to 1.0 m above the pre-dam flood level. The presence of *Melanoides tuberculata* indicates permanent water and *Pila wernei* and *Lanistes carinatus*, being amphibious species, could indicate seasonal inundation. Their presence suggests a mixed assemblage of shells such as could occur at the boundary between permanent water and seasonally inundated swamps. The close alternation of rippled sands and clays in the horizon immediately below laminated grey silts is consistent with seasonal deposition between high and low water

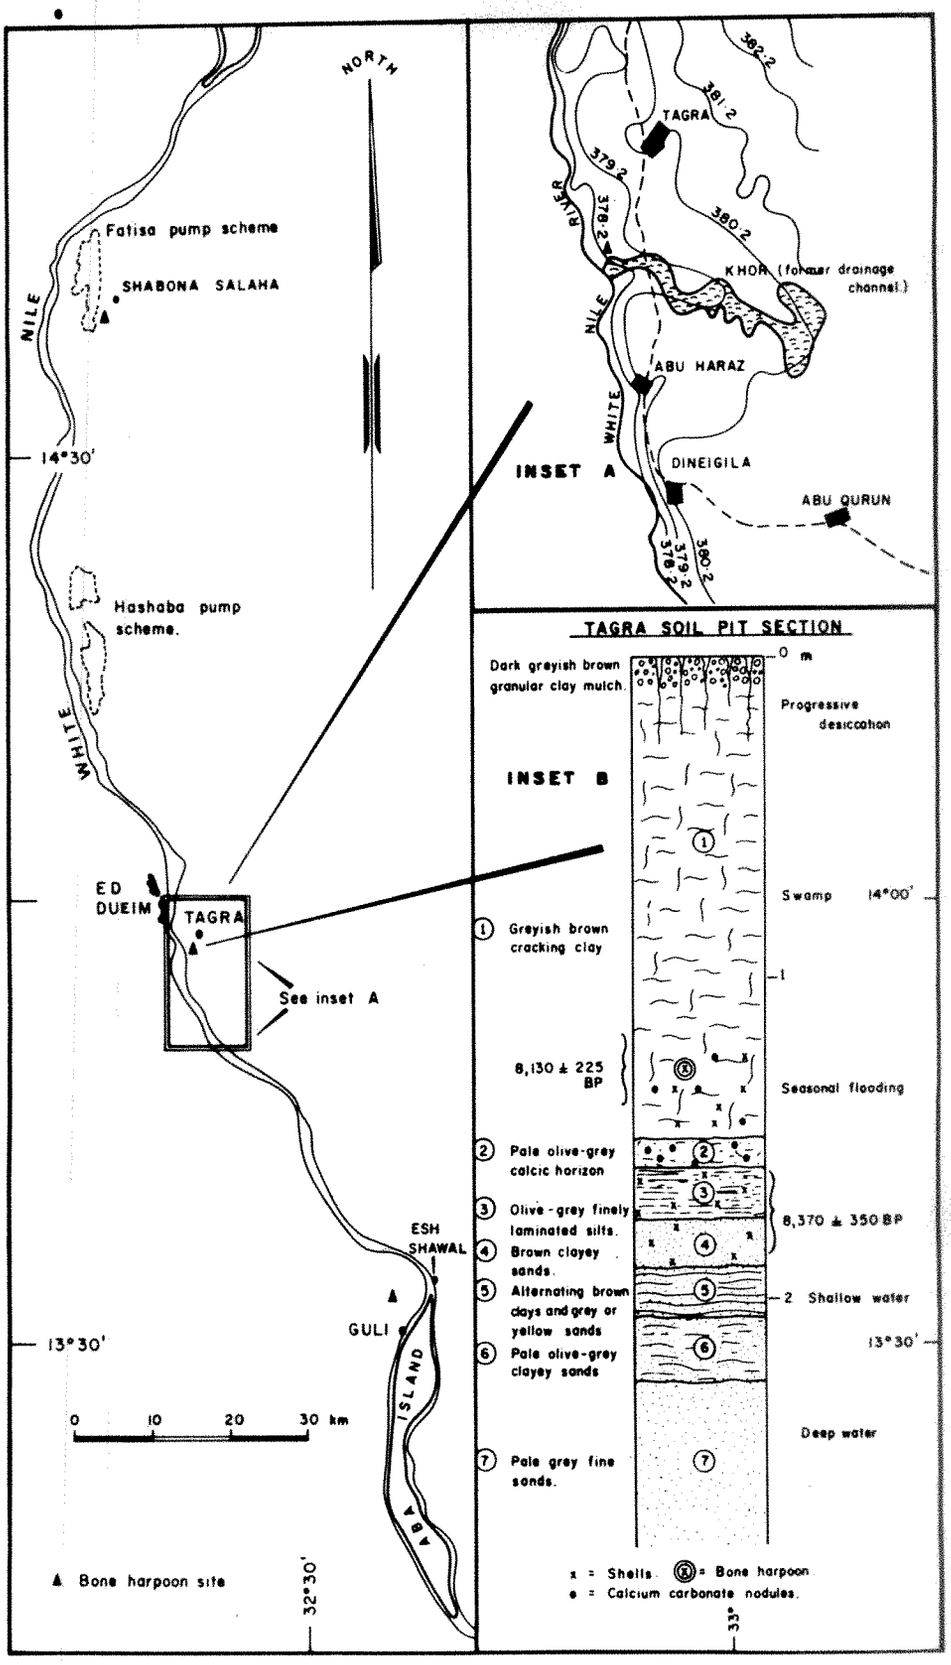

FIG. 1 Location of the three sites in Central Sudan, with inset showing section of soil pit at Tagra.

level. The limonite bands between gleyed silt laminae also suggest an alternation of oxidising and reducing conditions associated with seasonal deposition in a shallow littoral environment.

The deposition of clay, the calcic layer, the absence of permanent-water mollusca and the signs of human activity are also consistent with the cessation of permanent water conditions and a change to seasonal inundation. The clay indicates inundation by slow moving water carrying only fine sediment. The site may have been subject to the type of annual flooding and partial drying which now occurs in 'toich' soils which adjoin rivers or 'khors' in the permanent swamps of the Sudd region in the southern Sudan[8]. A zone of carbonate accumulation, which may mark the depth of

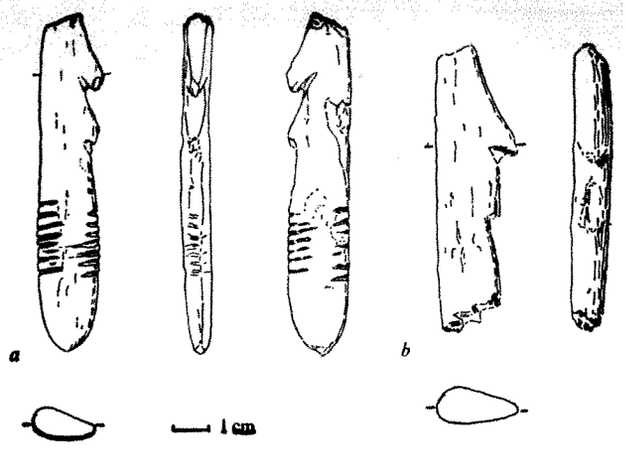

FIG. 2 *a*, Tagra bone point fragments after joining; *b*, Guli specimen (drawn by R. Vermilion).

seasonal drying, is common in 'toich' soils and the horizontal calcic band in the Tagra profile may be analogous. If the permanent, dry season water level of the White Nile was about 376–377 m, the flood season levels would have created 'toich' conditions at this site during the whole period of clay deposition.

The recession of the White Nile and the end of clay deposition by seasonal flooding at this site was governed by the down-cutting of the Blue Nile and consequent lowering of the White Nile[7]. The White Nile fell by about 4 m within the past 6,000–8,000 yr, sufficient to account for a lowering of the level of permanent water, that is dry season level, at this site from about 376–377 m to the present pre-dam level of 372.2 m. The effect of the Jebel Aulia dam when full is to raise the White Nile close to its prehistoric dry-season level of 8,000 yr ago.

Guli site

A second fragment of barbed bone point, heavily encrusted with calcium carbonate, was found on a small sandy island in the White Nile swamps near Guli (Fig. 1) at 13°34′N, 32°34′E at an estimated elevation of about 378.5 to 379 m, that is about 1 m above the present high water level caused by the Jebel Aulia Dam (377.8 m). Before completion of the dam, the maximum White Nile level, estimated by interpolation between the Ed Dueim and Rabak gauges, was about 375.6 m and the minimum about 373.0 m. The island is part of an old point bar in the large area of swamps and point bars, about 7 km wide, on the west side of the river opposite Esh Shawal. The bone tool was found accidentally while sampling a dense deposit of *Pila wernei* shells (0-35 cm deep) for purposes of radiocarbon dating. The spoil from a drainage ditch across one corner of the deposit revealed abundant potsherds with impressed fish-spine decoration, fossilised and subfossil fish bones, and subfossil *Pila* shells, indicating that the shell deposit was associated with an old occupation site. The *Pila* shells were predominantly mature specimens averaging 30–50 mm, with large specimens up to 90 mm long. The whole shell assemblage was evidently not a natural one and this suggests that they were collected and brought to the occupation site as food and/or bait. A sample of shell from a depth of 30–35 cm in the midden gave an age of 5,500 ± 90 yr BP (or 3530 ± 90 b.c.) (SUA-211) thus suggesting that the Guli site is contemporaneous with the "Khartoum Neolithic" tradition as represented at Esh Shaheinab and other sites north of Khartoum.

Bone point fragments

The Tagra bone point fragments (Fig. 2*a*) have been cleaned and the carbonate removed by the Technical Department of the British Museum (Natural History) to the staff of which our thanks are gratefully acknowledged. After the two fragments are joined, the specimen is seen to comprise the butt end and two partially damaged barbs, both on the same lateral edge. The distal end of the specimen is missing but there is no noticeable convergence of the lateral edges so that it is likely to have been furnished with at least one additional barb. The existing length is 91 mm; the maximum breadth at the upper barb is 18 mm and, at a distance of 21 mm from the proximal end, the maximum breadth is 16 mm. In section it is a flattened elipsoid, more or less the same thickness throughout its length — 7.5 to 7.0 mm.

The specimen is made from a longitudinally split fragment of long bone from a large mammal, rubbed smooth and polished on a grindstone. This smoothing and grinding have been insufficient to remove entirely evidence of the cancellous bone on the interior surface. The barbs have been made by working on each face opposed V-shaped grooves; these were set obliquely to the long axis and deepened so as to intersect at the edge. The intersection was then worked back by further transverse rubbing to deepen and enlarge the barb. The backs of the barbs are slightly concave, as in many of the "Early Khartoum" examples, and although the tip ends have been broken away, they may similarly have been given a reverse curve, for the beginnings of such can be detected on the upper of the two surviving barbs.

As in the uniserially barbed bone points from "Early Khartoum", the Tagra specimen has also been provided with seven obliquely cut grooves between 40 mm and 21 mm from the proximal end. These grooves are believed to serve as an anchor for the binding that secured the point to the shaft so that, since the butt carries no perforation, the specimen is technically the non-detachable point of a spear rather than a harpoon.

The Tagra specimen closely resembles the "Early Khartoum" points in general dimensions, nature of barbs and grooving of the rounded butt end. Only a small number, however, out of more than 270 fragments at "Early Khartoum" have a flattened, elipsoidal cross-section, most being circular or elliptical in section. Variability of this kind is not unexpected between independent settlements of this kind over 180 km apart. There is, however, no indication that the Tagra point was associated with any living site debris; it seems to be an isolated find that had, probably, been lost in use away from the immediate settlement area.

The specimen from Guli (Fig. 2*b*) is the central portion of a similar uniserially barbed bone point; the distal and proximal ends are both missing. It is 76 mm long, 22 mm broad across the first barb and the thickness varies between 9.0 mm and 8.0 mm. It is made in a similar way from a segment of longbone rubbed down on a sandstone grinder. The upper of the two barbs is complete but only the basal part of the second, adjacent to the stem, is preserved. The back of the complete barb exhibits the concavo-convex profile characteristic of the bone points and harpoons from both "Early Khartoum" and Esh Shaheinab. The section across the surviving barb is a flattened elipse, similar to that of the point from Tagra. The missing distal portion probably ended in a point as it can hardly have been either long or broad enough to accommodate another barb unless this was of a vestigial nature. Similarly, there is no indication from the remaining length of the proximal end that there were ever more than two barbs. Although rare, forms with only two barbs are known from both "Early Khartoum" and Esh Shaheinab. The specimen is coated with a carbonate skin which has not yet been removed, but there is nothing to lead one to suspect that the butt end bears groovings characteristic of points of "Early Khartoum" type. Neither is the surviving portion lugged and perforated as were the Neolithic harpoons, however, since the butt itself is missing, it is not possible to be certain that it may not have been pierced for

the attachment of a line, though this seems unlikely.

The Guli example resembles more closely, therefore, the "Early Khartoum" type of bone point than it does the perforated and lugged type of harpoon from Esh Shaheinab, although the radiocarbon determination suggests that it is more closely related in time to the Neolithic than the "pre-Neolithic". Stylistic preferences and time differences between river bank settlements at this time are surely to be expected, as also is variability due to differences in the local availability of specific resources at the different sites and so in the equipment with which these were exploited. The Neolithic bone harpoon may well be related to hippo-hunting from dugouts or reed boats, as Arkell has previously hinted (ref. 2, page 31). The barbed bone point, on the other hand, is more probably a spear for Nile perch and mud fish as well as for land mammals; barbed spears and harpoons have a very long history in the Nile basin[8] and in the west African Sahel[9].

The pottery from Guli shows affinities with the Khartoum Neolithic impressed wares though there are no sherds of "Burnished Dotted Wavy-Line" or opposed triangle impressed pottery in the collection. The majority of sherds seem to come from well-fired, deepish spherical bowls with inturned rims, the upper half at least of the exterior of the pot, and sometimes the lip, being decorated with horizontal rows of impressed dots, some executed with a comb (cat fish spine or stamp) and others again with a rolled cord or grass roulette (compare ref. 2, plate 29:2). Rocker stamp decoration occurs on the interior of one sherd and the rim of a second. Another shows two rows of stamping on the rim and parallel grooving below; the sherd is also perforated. Another rim sherd shows a stamped chevron design such as occurs rarely also at Esh Shaheinab. These sherds are comparable also to the Khartoum Variant pottery from the 2nd Cataract and that from the Khashm el Girba region on the Upper Atbara which is similarly unburnished[10]. The pottery confirms in general, therefore, the age determination of the Guli midden and bone point fragment.

Age determinations on bone, shell and charcoal from the pre-Neolithic settlement at Shabona have not yet been received, but the similarity of the barbed bone points from this site (where the flattened section is more common than the circular form) and those from "Early Khartoum" to the Tagra specimen, suggest that this particular industrial tradition most probably belongs in the seventh and sixth millennia bc. The "Early Khartoum" tradition had been replaced by that of the Khartoum Neolithic, which grew directly out of it, by the middle of the fourth millennium bc on the evidence of the dates from Esh Shaheinab and Guli, but its lower limit has yet to be determined. There is every indication that it was a tradition of long duration evolving out of the local late Palaeolithic and early epi-Palaeolithic industries, through the gradual development of a specialised waterside technology and the acquisition at different times in its history of pottery and other improved cultural traits.

The only other early site on the Nile yielding barbed bone points is the fishing camp of Cat Fish Cave in Upper Egypt (22°43′N, 32°07′E) dating to before 6400 b.c.[11]. No pottery was found here but the points bear only general resemblance to those of the "Early Khartoum" tradition. There is no pottery either at the epi-Palaeolithic site of El Kab (c. 25°15′N, 32°53′E) dating to 6400± b.c., neither, however, are there bone points[12]. Pottery is again absent from the epi-Palaeolithic sites found by Wendorf[13] in the Fayum depression and dating between 5190 ± 120 and 6150 ± 130 b.c. A specialised form of barbed point made from a cat fish spine is associated with these small fishing camps. The absence of pottery from these seventh millennium sites in Egypt suggests, therefore, that the Tagra barbed bone point might belong to a similar early Holocene local Sudanese tradition that had not yet developed the art of pottery making. On the other hand, if the dates from Shabona prove to be coeval with that from Tagra, the possibility that the characteristic "Wavy-Line" pottery and other wares of "Early Khartoum" type were an early and independent development on the Upper Nile or in the Sahara, as Arkell has suggested[14], becomes much more likely.

Localisation of a fibroblast growth factor and its effect alone and with hydrocortisone on 3T3 cell growth

Denis Gospodarowicz

The Salk Institute for Biological Studies, PO Box 1809, San Diego, La Jolla, California 92112

FGF, a polypeptide found in brain and pituitary, provokes the initiation of DNA synthesis by resting 3T3 cells. When glucocorticoids are present FGF stimulates DNA synthesis as effectively as serum.

MULTIPLICATION of animal cells *in vitro* requires certain macromolecular factors which are usually found in serum. Since none of these factors, except for somatomedin A[1,2] had been isolated until recently, their mode of action has remained unclear. It is also unclear whether one or more of these factors is required to initiate division *in vivo* or *in vitro*. It has been suggested[3–7] that the pituitary gland is a source of growth factors *in vivo*. Bovine pituitary glands have yielded an ovarian growth factor which controls the division of an ovarian cell line[4]. Other reports describe the presence in impure preparations of pituitary hormones such as thyroid stimulating hormone and luteinising hormone of factor(s)

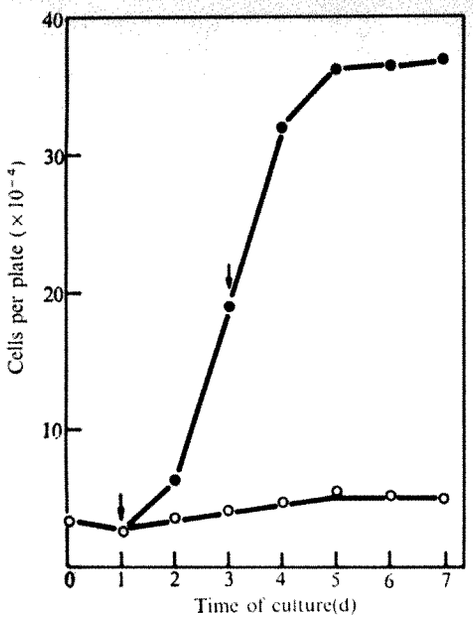

FIG. 1 Stimulation of division of resting 3T3 cells by FGF. 3T3 cells were plated in Dulbecco's modified Eagle's medium (DME) in the presence of 10% calf serum (4×10^4 cells per 60×15 mm plate). Eight hours later the medium was changed to DME with 0.4% calf serum (day 0). On day 1 and day 3 (arrows), the FGF was added (50 ng ml^{-1}). The number of cells per dish was counted every day and plotted against time both in the presence (●) and the absence (○) of FGF.

able to stimulate growth of chondrocytes[5] or 3T3 cells[6,7].

To ascertain whether or not the pituitary is the sole source of growth factors, crude extracts of a variety of bovine organs were tested for their ability to stimulate division of resting 3T3 cells. The highest concentration of fibroblast growth factor (FGF) was found in the brain. Pituitary extract was five to ten times less potent. Although FGF has been purified from the pituitary[8], the effort to purify it from the brain has been impeded by the high concentration of basic polypeptides of low molecular weight present in brain extracts. These polypeptides remain associated with the FGF making its purification from brain more difficult than from pituitary.

Studies of the control by purified FGF of the division of resting 3T3 cells maintained at low serum concentration have shown the stimulation of DNA synthesis by FGF to be less than that induced by a high serum concentration. For maximal DNA synthesis, hydrocortisone (a glucocorticoid) is required. This requirement is similar to that of an ovarian cell line[3], which requires dexamethasone or hydrocortisone for full cell division. In serum-free medium, FGF plus hydrocortisone stimulates DNA synthesis in a manner comparable with serum.

Localisation of activity

Growth factor activities of crude extracts of the following organs from freshly slaughtered cows were compared: heart, liver, muscle, pituitary, brain, placenta (cotyledon), adrenal cortex, adrenal medulla, ovary and lung. Each tissue was homogenised at 4°C in 0.15 M $(NH_4)_2SO4$ in a Virtis homogeniser. The *p*H was adjusted to 4.5 and the homogenate was allowed to stand in the cold. After 2 h the homogenate was centrifuged and the supernatant was dialysed against deionised water overnight. The extract was then centrifuged again; the supernatant was lyophilised and stored for use.

The 3T3 cells used were grown in DME (Dulbecco's modified Eagle's medium) supplemented with 10% calf serum (Colorado Serum Co. Laboratories) and incubated at 37°C in a CO_2 and humidity controlled incubator. The cells were collected routinely using trypsin (0.25% in phosphate-buffered saline). Aliquots of the washed cells were plated onto plastic tissue culture dishes (Falcon). The serum concentration was decreased to 0.4% to make the cells enter a resting stage (Fig. 1). DNA synthesis was assayed quantitatively by measuring ^{3}H-thymidine incorporation into trichloroacetic acid-precipitable material.

When brain or pituitary extracts were added to cultures of resting 3T3 cells, DNA synthesis was enhanced in proportion to concentration (Fig. 2). In contrast, muscle and kidney extracts were inactive except when high concentrations (2.5 μg ml^{-1}) of protein were present. The slight growth factor activity of kidney extracts was consistent with the activity to be expected due to the presence of serum in the kidney at the time of extraction.

The effects of crude extracts of diverse tissues is presented in Table 1. The incorporation of ^{3}H-thymidine by 3T3 cells is clearly much higher in the presence of crude brain or pituitary extract than in the presence of extracts from any other tissue tested. The slight degree of stimulation by extracts from other tissues can, in certain cases, be attributed to their serum content. For example, if liver is perfused with saline before extraction most of the stimulatory effect disappears.

Brain extract was a more potent stimulant of DNA synthesis than pituitary extract (Fig. 2). The minimum concentration of brain extract which stimulated ^{3}H-thymidine

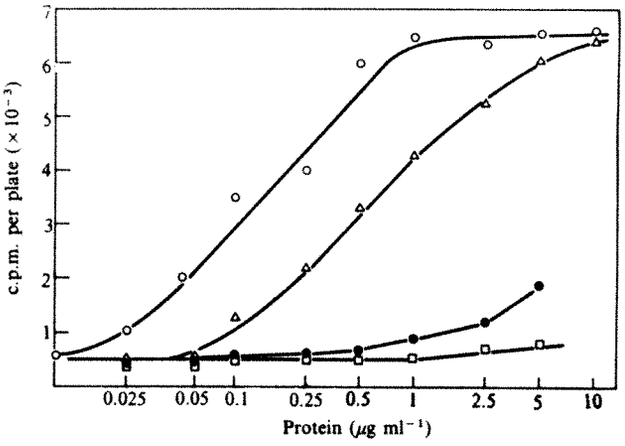

FIG. 2 DNA synthesis in 3T3 cells in response to various concentrations of diverse crude extracts. 3T3 cells were plated in DME with 10% calf serum (4×10^4 cells per 60×15 mm dish with 5 ml of medium per dish). Eight hours later the medium was removed and replaced by DME with 0.4% calf serum. Twenty-four hours later the same washing was repeated after which the cells were maintained for 3 d without changing the medium. On day 3, various concentrations of samples dissolved in the presence of 0.5% crystalline bovine albumin (to minimise nonspecific adsorption) were added to the cultures. Samples were added in fluid volumes ranging from 25 to 100 μl. Sixteen hours later, 50 μl of DME containing 10 μCi of ^{3}H-thymidine (^{3}H-methyl, NEN) and 6 μg of cold thymidine were added to each dish. After 11 h incubation at 37° C the dishes were washed once with a buffered salt solution, after which 2 ml of 0.5 N NaOH was added and the dishes were further incubated for 8 h at 37° C. DNA was then precipitated by adding trichloroacetic acid (TCA) to a final concentration of 10%. The precipitates were collected on Whatman GF/C glass fibre filters, washed twice with 10% TCA and counted (scintillation counter with toluene-PPO-POPOP solution) as radioactivity incorporated in DNA. The incorporation of ^{3}H-thymidine was 650 c.p.m. per dish in controls. All points were done in triplicate. Standard errors did not average more than 10% of the mean. ○, Brain; △, pituitary; ●, kidney; □, muscle.

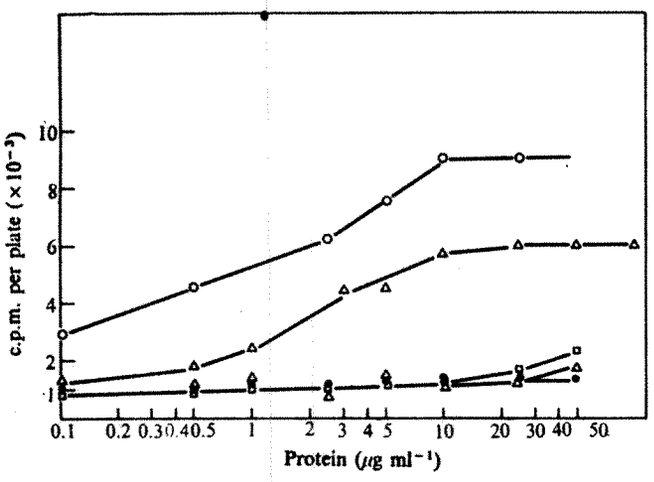

FIG. 3 DNA synthesis in C6 glial cells in the presence of various concentrations of diverse crude extracts. C6 cells were grown as described for 3T3 cells. Cells were plated in DME plus 5% calf serum (6×10^4 cells per 60×15 mm dish with 5 ml of medium per dish). Eight hours later the medium was removed and replaced with DME plus 0.2% calf serum. Twenty-four hours later the same washing was repeated after which the cells were maintained for 3 d without changing the medium. On day 3, various concentrations of samples dissolved in the presence of 0.5% crystalline bovine serum albumin (to minimise nonspecific adsorption) were added to the cultures. Samples were added in fluid volumes ranging from 25 to 100 μl. Determination of ^{3}H-thymidine incorporation was as described in Fig. 2. The incorporation of ^{3}H-thymidine was 850 c.p.m. per dish in controls. All points were done in triplicate. Standard errors did not average more than 10% of the mean. ○, Brain; △, pituitary; □, liver; ●, adrenal cortex; △, ovary.

incorporation was 25 ng ml^{-1} compared with 100 ng ml^{-1} for pituitary extract. This is a comparison of pituitary extract and extract of whole brain. If growth factor activity in the brain can be localised to some small region, the specific activity of that region will be much greater than that of the more 'dilute' whole brain preparation and, accordingly, much greater than that of the pituitary extract.

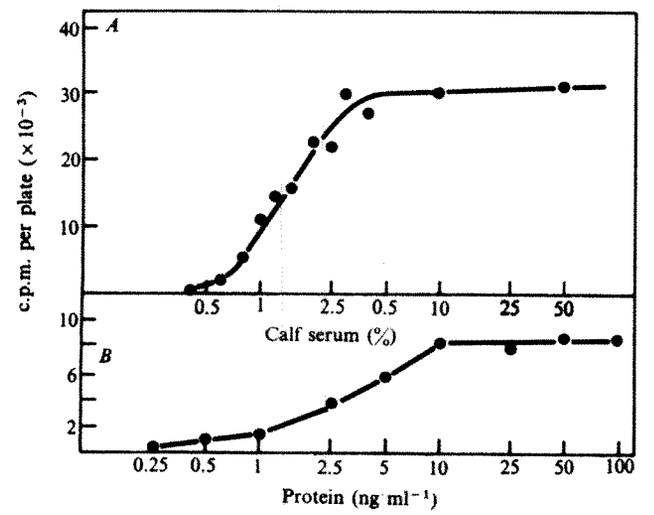

FIG. 4 DNA synthesis in 3T3 cells in the presence of serum compared with FGF. 3T3 cells were plated and maintained as described in Fig. 2 (4×10^4 cells per 60×15 mm dish). The incorporation of ^{3}H-thymidine was 600 c.p.m. per dish in controls. *A*, Effect of increasing concentrations of calf serum on the incorporation of ^{3}H-thymidine into DNA. *B*, Effect of increasing concentrations of FGF on the incorporation of ^{3}H-thymidine into DNA.

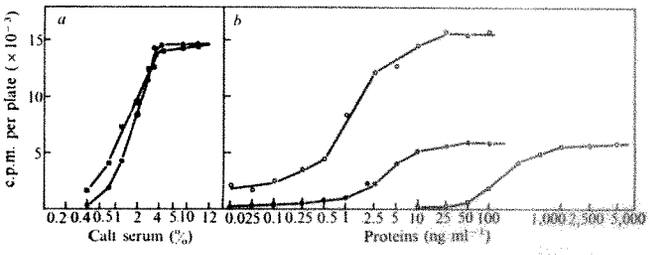

FIG. 5 DNA synthesis in 3T3 cells in the presence of serum, hydrocortisone and FGF. 3T3 cells were plated and maintained as described in Fig. 2 (2.4×10^4 cells per 60×15 mm dish). The experiment was conducted as described in Fig. 2. *a*, 3T3 cells maintained in the presence of increasing concentrations of serum (●) and serum + 0.5 μg ml^{-1} of hydrocortisone (■). The incorporation of H-thymidine was 300 c.p.m. per dish in the controls. *b*, 3T3 cells maintained in the presence of increasing concentrations of FGF in the presence (○) and absence (●) of 0.5 μg ml^{-1} of hydrocortisone. The stimulatory effect of NIH bovine LH-B-8 (bovine luteinising hormone) where the FGF is present as contaminant is shown by the lowest line. The purified FGF is about 200–500 times as potent as that preparation.

To test the ubiquity of the growth stimulating effect of brain and pituitary extracts cell lines other than 3T3 have been used. Figure 3 shows that the growth of C6 glial cells

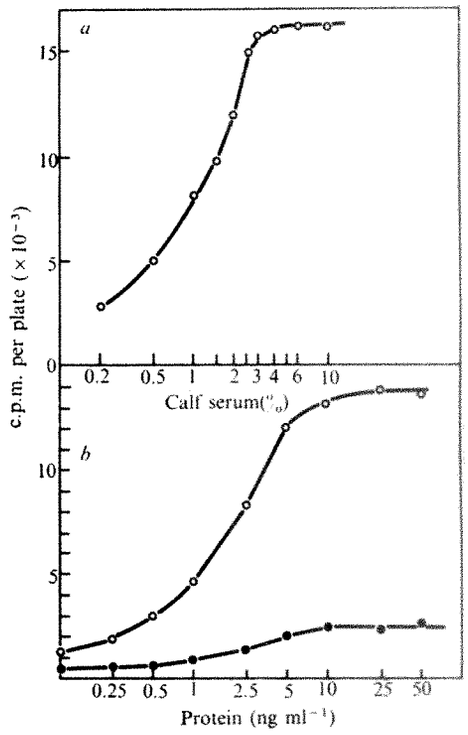

FIG. 6 DNA synthesis in 3T3 cells in the presence of either serum or FGF plus or minus hydrocortisone. 3T3 cells were plated and maintained as described in Fig. 2 (2.4×10^4 cells per 60×15 mm dish). Twenty-four hours before the addition of FGF and hydrocortisone the 0.4% calf serum medium was removed and replaced with DME containing 0.25% crystalline bovine serum albumin and 0.5 μg ml^{-1} of hydrocortisone; in some dishes, hydrocortisone was not added. Twenty-four hours later FGF and serum were added to the dishes in graded concentrations and the experiment was conducted as described in Fig. 2. The incorporation of ^{3}H-thymidine was 300 c.p.m. per dish in the controls. *a*, Effect of increasing concentrations of calf serum on the incorporation of ^{3}H-thymidine into DNA of 3T3 cells maintained in the absence of serum and in the presence of hydrocortisone. *b*, Effect of increasing concentrations of FGF on the incorporation of ^{3}H-thymidine into DNA of 3T3 cells maintained in the absence of serum and in the presence (○) or absence (●) of hydrocortisone.

TABLE 1 DNA synthesis in 3T3 cells maintained in the presence of increasing concentrations of various crude extracts

Crude extracts	Protein concentrations (ng ml^{-1})			
	100	250	1,000	5,000
Brain	4,600	8,500	10,200	9,500
Pituitary	2,500	5,100	7,600	10,200
Liver	680	1,000	1,860	3,600
Perfused liver	720	690	1,250	1,820
Cotyledon	620	650	1,200	1,150
Heart	610	670	750	1,600
Muscle	625	810	925	1,750
Ovary	650	710	1,200	1,560
Adrenal cortex	670	925	970	1,920
Adrenal medulla	580	570	420	750
Kidney	630	825	1,250	1,850

Results are expressed in c.p.m. of ^{3}H-thymidine incorporated into DNA. 3T3 cells were plated as described in Fig. 2 (32,000 cells per 60 × 15 mm dish) and ^{3}H-thymidine incorporated into DNA was assayed as described in Fig. 2. The incorporation of ^{3}H-thymidine was 630 c.p.m. per plate in the controls. All points were done in triplicate and standard errors did not average more than 10% of the mean.

is also stimulated. This cell line was chosen because the cells remain differentiated in culture, as demonstrated by the existence of a functional nor-adrenaline receptor[9] and by their secretion of S_{100} protein, a specific marker for glial cells[10]. As with 3T3 cells, C6 cells respond to crude brain and pituitary extracts by an increase in DNA synthesis. However, C6 cells are less sensitive to the extracts than are 3T3 cells. Furthermore, the maximum level of stimulation produced by brain extract is twice that produced by pituitary extract. Extracts of other tissues had no effect (Fig. 3). I now have evidence that crude extract of brain or pituitary can induce division not only of 3T3 and C6 cells but in primary cultures of glial cells as well. The growth factor activity in pituitary and brain is then not restricted to a single cell type.

Purification and activity

The purification of FGF from pituitary glands (described in full in ref. 8) is briefly as follows. Bovine pituitary glands are extracted at *p*H 4.5 with 0.15 M $(NH_4)_2SO_4$. Addition of HPO_3 to *p*H 3.0 removes an inactive fraction. FGF activity was precipitated between 2.34 and 3.8 M $(NH_4)_2SO_4$ at *p*H 7.0 and further purified by carboxymethycellulose chromatography. The activity was adsorbed from 0.01 M potassium phosphate, *p*H 5.9, and eluted with 1 M NaCl and 0.1 M potassium phosphate, *p*H 5.9. Further purification was achieved by chromatography on Sephadex G-75 and Sephadex SE C-50. The yield of purified FGF averaged 1 mg kg^{-1} of pituitary. Acrylamide gel electrophoresis at *p*H 4.5 (ref. 11) revealed a single band. Contamination by pituitary hormones was negligible.

As mentioned earlier, purification of the FGF from the brain is more difficult and has progressed more slowly. An effort is under way to purify FGF from the brain in order to determine whether or not it is identical to the FGF purified from the pituitary.

When purified FGF was added to resting 3T3 cells maintained at low serum concentration, they entered a division cycle as evidenced by an increase in cell number compared with controls, and as demonstrated by autoradiography (Fig. 1).

The initiation of DNA synthesis by 3T3 cells maintained in the presence of 0.4% calf serum in response to FGF was assayed quantitatively by measuring ^{3}H-thymidine incorporation into trichloroacetic acid-precipitable material. As Fig.

TABLE 2 Degree of stimulation or inhibition by steroids on the incorporation of ^{3}H-thymidine into DNA of 3T3 cells maintained in the presence of FGF

Steroids	Conc. (μg ml^{-1})	^{3}H-thymidine (c.p.m.)	Inhibition* (%)	Steroids	Conc. (μg ml^{-1})	^{3}H-thymidine (c.p.m.)	Inhibition (%)	Stimulation† (%)

	10.0	(−)680	100					

3T3 cells were plated and maintained as described in Fig. 2 (3.2 × 10^4 cells per 60 × 15 mm dish). On the day of the experiment, FGF (50 ng ml^{-1}) plus the different steroids were added to the dishes. The steroids were added in a final volume of 25 μl of ethanol. Serum was added to a final concentration of 8%. Thymidine incorporation was measured as described in Fig. 2 and the radioactivity incorporated into DNA in the presence of FGF was compared with that obtained in the presence of FGF plus steroids and in the presence of 8% serum. The incorporation of radioactivity in controls was 800 c.p.m.; this value has been deducted from the values obtained with FGF, FGF plus steroids and 8% serum.

* Inhibition values are expressed as percentage of the difference between FGF and control levels with control levels (800 c.p.m.) and below defined as 100% inhibition.

† Stimulation values are expressed as percentage of the FGF stimulation.

‡ In some cases the radioactivity incorporated into DNA when FGF plus steroids were present was less than that of controls; this is indicated by the sign (−).

4 shows, when increasing concentrations of FGF were added to resting cells they started to make DNA more actively. The minimal effective dose of FGF was about 0.1 ng ml^{-1} and plateau values were 5–10 ng ml^{-1} (Figs 4 and 5). Based on a molecular weight of 13,000 (ref. 8) this represents a concentration of 1×10^{-9}M. These concentrations are comparable with the physiological concentrations of polypeptide hormones in serum and are indicative of the potency of the FGF.

The maximal stimulation of DNA synthesis by FGF is about 30% of that observed with optimal serum concentration (Figs 4 and 5). This could indicate either that only 30% of the FGF-stimulated 3T3 cells enter the proliferative phase, or that the serum-containing medium stimulates more complete division, thus inducing additional DNA synthesis. The first hypothesis was rejected since autoradiography indicated that the entire 3T3 population was actively engaged in DNA synthesis when stimulated by FGF. The second hypothesis was explored by seeking factors which can potentiate the effect of FGF. It has been shown for many biological systems that glucocorticoids potentiate (permissive effect) the biological effect of polypeptide hormones[12]. Thrash and Cunningham have reported the stimulation of division of density inhibited fibroblasts by glucocorticoids[13] and Armelin has reported that glucocorticoids enhanced pituitary growth promoting activity[6]. These observations have led me to examine the effect of hydrocortisone and dexamethasone on FGF-stimulated DNA synthesis. Figure 5 shows that when 3T3 cells were maintained in the presence of FGF and hydrocortisone, the degree of incorporation of ^{3}H-thymidine into DNA became comparable with that found in the presence of serum. Furthermore, hydrocortisone did not potentiate the stimulatory activity of serum except when the serum was present in small concentrations. This can be interpreted as indicating that the concentration of hydrocortisone in serum is optimal to provoke maximal DNA synthesis. However, at low serum concentrations the hydrocortisone concentration is too low to be effective.

Progestogen, androgen and oestrogen were also tested for their permissive effect on the action of FGF. As Table 2 shows, androgen and oestrogen have an antagonistic effect on the incorporation of ^{3}H-thymidine into DNA. In the presence of high concentrations (10 μg ml^{-1}) incorporation could even decline to less than that observed with control 3T3 cells maintained without FGF. Progesterone in low concentrations had no marked inhibitory effect; however, when the concentration was increased to 10 μg ml^{-1}, ^{3}H-thymidine incorporation was inhibited completely. This effect of progesterone was interesting because the compound can compete for the receptor site of glucocorticoids[14].

In contrast to oestrogen, androgen and progestogen, glucocorticoids were agonistic with the exception of dehydrocortisone which was antagonistic. As expected from the previous results, dexamethasone and hydrocortisone were the most potent agonists and brought the incorporation of ^{3}H-thymidine to a level similar to that observed in the presence of high serum concentration.

If FGF and hydrocortisone are the only factors required for the control of 3T3 cell division, serum requirements for 3T3 cells can be replaced by those agents. As Fig. 6 shows, when 3T3 cells are maintained in the presence of 0.2% bovine serum albumin and hydrocortisone (0.5 μg ml^{-1}) they enter a resting stage. When FGF is added, DNA synthesis is initiated. The level of stimulation observed in the presence of an optimal concentration of FGF is comparable with that obtained with serum.

In summary, induction of 3T3 cell division requires only two agents, a polypeptide which has been purified from the pituitary gland and a glucocorticoid-hydrocortisone. Although the nature of the permissive effect of glucocorticoids on FGF activity can only be the object of speculation, glucocorticoids may be involved in the control of one or more components of the FGF effector system. An attractive possibility is that they modulate the receptor site for FGF; thus, in the absence of glucocorticoids, few or no receptor sites would be present, resulting in little activity of FGF. In their presence, the number of active sites would be induced maximally, leading to maximal activity of FGF. A similar hypothesis for the permissive effect of glucocorticoids on the lipolytic activity of luteinizing hormone[15] and thyroid stimulating hormone[16] has already been suggested.

It should be kept in mind that if glucocorticoids are needed for the induction of 3T3 cell division, that requirement does not necessarily apply to all types of cells. For L929 fibroblasts glucocorticoids are inhibitory[17].

Finally, it should be pointed out that in all the experiments only the initiation of 3T3 cell division and DNA synthesis for which I think the FGF associated with hydrocortisone is responsible have been investigated. The results do not exclude the possibility of the presence in serum of other factors which may affect cell plating, attachment and survival[18,19]. However, the acquisition of a highly purified polypeptide which triggers division of 3T3 cells *in vitro* should facilitate the study of the initial events which commit the cell to divide.

Seafloor spreading theory and the odyssey of the green turtle

Archie Carr
University of Florida, Gainesville, Florida

Patrick J. Coleman
University of Western Australia, Perth, Western Australia

Seafloor spreading theory seems to explain why the ancestors of a green turtle (Chelonia mydas) *subpopulation which now travels 2,000 km from Brazil to breed at Ascension Island, were induced to swim oceanwards for increasing distances during the gradual separation of South America and Africa in the earliest Tertiary.*

A SUBPOPULATION of the green turtle (*Chelonia mydas*) lives on the coast of Brazil but breeds and nests 2,000 km away on Ascension Island in the central equatorial Atlantic[1-6]. The feat of navigation involved in this odyssey has not been explained[5,7]. A puzzle of equal stature, and of more fundamental importance, arises in trying to account for the initial stages in the evolution of the adaptation[3,4]. Populations of the genus *Chelonia* have distinctive characteristics—enormous shoulder musculature together with its support, heavy fat deposits, and a peculiar jaw structure. The ecological regimen responsible for these characteristics is evidently the herbivorous feeding habit[1,8] and the need that this imposed for travel between a protected, shallow water pasture ground and the exposed shores on which suitable nesting beaches develop. Offshore and oceanic islands are likely to have good surf-built beaches and they almost always offer relative freedom from the nest-predators which plague mainland nesting beaches. In spite of these advantages, however, the Ascension colony has established the adaptations in the face of huge difficulties, inherent in the initial stages, which seem to make impossible demands on the process of natural selection. Seafloor spreading theory may bear directly upon this aspect, and it also offers clues to the navigation problem.

Turtles and central Atlantic opening

Marine turtles of *Chelonia* type inhabited the seas between 'North America' and northwestern Gondwanaland by the beginning of the late Cretaceous, about 100 million years (Myr) ago. Because of the cheloniid fossil record in this general area (refs 9–12 with the references provided there), we postulate that these ancient turtles included the ancestors of *Chelonia mydas*, even though its phylogeny cannot at present be reconstructed. (*Chelonia* has been found in Miocene sediments[9,10].) The northern coast of South America was a suitable habitat for these early turtles, providing a tropical to subtropical environment. There is fossil evidence that even then the herbivorous habit had evolved and that there was a separation of residence-pasture and breeding grounds[12]. Mammalian egg-predators no doubt acted as a limiting factor in turtle ecology at this time, augmenting the advantage in island nesting.

The opening of the equatorial Atlantic[13-16] (Fig. 1*a* and *b*), marking the final separation of South America and Africa at about 80 Myr ago, took place in steps: first, rift valley formation at about 110 Myr ago, or even earlier; second, sporadic but progressive ocean flooding with a strong west-to-east component by 90–80 Myr ago; and finally development of a ridge system which linked the spreading ridges of the North and South Atlantic and made of it a single ocean by 80 Myr ago.

Volcanic piles are a frequent feature of midoceanic ridges, and some may grow sufficiently to emerge as islands. As spreading

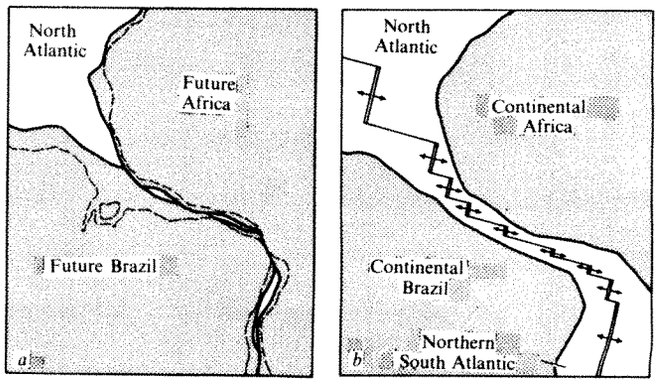

Fig. 1 *a*, Predrift reconstruction of equatorial 'South America' and 'West Africa', as parts of north-western Gondwanaland, based on the computer-tested bathymetric fit of Bullard *et al.* (ref 23). *b*, Reconstruction for the time of about 80 Myr ago. A 'Red Sea' connects the northern Atlantic with the younger southern Atlantic and its youthful spreading ridge. Spreading ridge detail is schematic.

continues, they become inactive and are carried outwards and downwards and become seamounts[17], the deepest being furthest from the ridge axis. They are sporadically replaced by new volcanoes on the ridge so that for the continental observer the volcanoes march seawards through time (Fig. 2). The ancestral turtles could thus migrate outwards with the volcanic islands, without the demands on the process of natural selection becoming excessive.

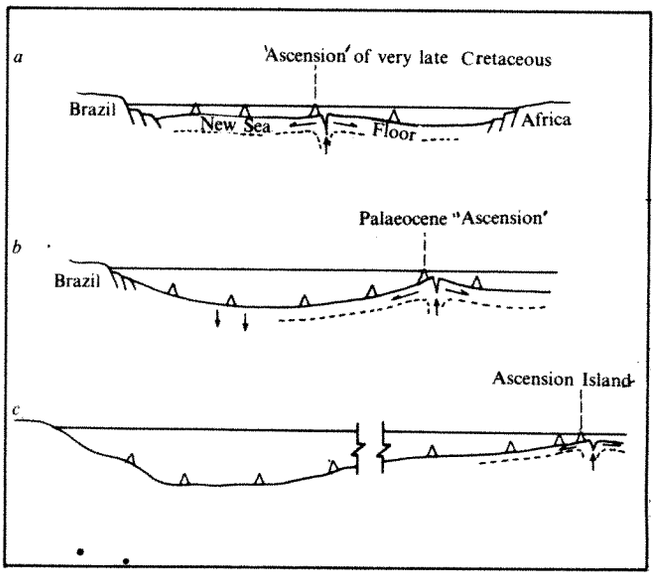

Fig. 2 The progressive appearance, then disappearance, of spreading ridge volcanoes as part of seafloor spreading mechanism. *a*, Approximately 70 Myr BP; *b*, approximately 60 Myr BP; *c*, approximately 1 Myr BP.

Turtle movement into the Brazil–West African channel

Before 100 Myr ago, turtle populations travelled between residence-pasture and breeding grounds along the shores of northern South America. By 90 Myr ago, a corridor had opened at the head of the gulf between Brazil and West Africa in line with the established longshore travel paths. By 80 Myr ago, the corridor was complete, much new coastline had been added, and there was a string of offshore islands. The exploitation of this oceanic channel by the turtles simply required repetitive extension of previous travel paths (Fig. 3). The bearings were WNW–ESE. This is close to a latitudinal course, and could be navigated relatively easily. Locating a particular beach on an island within this narrow sea or along its coasts would involve a longitudinal fix: local currents, rivers, even surfbeat, would offer individual signatures. It seems reasonable to assume that this pattern of travel, constant over a long period of time would become an established, heritable part of the turtle's behaviour.

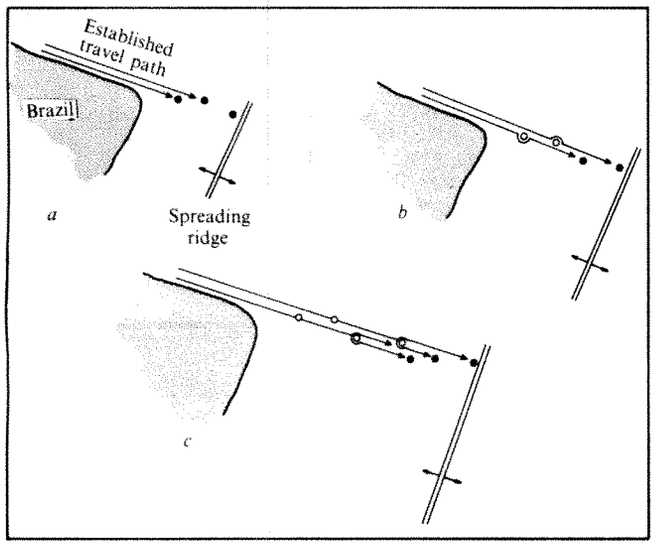

Fig. 3 As seafloor spreading proceeds, through stages *a*, *b* and *c*, new volcanic islands are generated near the ridge crest (double line). Older ones have moved out with the flanks of the ridge and gradually sink until they are submarine (open circle). As a former breeding ground becomes unusable, the turtle swims further on the same, or nearly the same, course.

By 80 Myr ago the Brazil–West Africa sea channel had connected with the northern South Atlantic and its active spreading ridge (Fig. 1*b*). The ridge volcanoes which had formed earliest, were close to those which had arisen or were still arising at the eastern end of the sea channel. For these new ridge islands to become included in the range of breeding grounds it was necessary only that some turtles extend their travel path, that is, simply stay on course, assuming either that the turtle was distracted from its prime target; or that the target had become submerged and unusable. On return trips the turtles would be guided to the final landfall by chemical cues, by surfbeat or even by direct vision. A degree of elasticity in the establishment and recognition of breeding grounds is necessary, but not much more than seems consistent with that found in the modern green turtle[18].

We envisage that by 70 Myr ago, the ancestors of the Ascension Island colony were making seaward breeding migrations of up to 300 km—a figure consistent with the spreading rate of 2 cm yr^{-1} (refs 14, 19). This process continued (Fig. 3) assuming there was sporadic creation of volcanic islands; Ascension Island is the last and youngest of them (less than 7 Myr old[19,20]). What was probably the penultimate island is now a seamount 15 km away, which is submerged to a depth of 1,500 m (ref 21).

We cannot establish the existence of a narrow swathe of seamounts connecting north-east Brazil with Ascension Island, because the detailed bathymetry is not well known. There is, however, a suggestion of a line of seamounts running south-eastwards from near Recife to about 30° W and then swinging east to Ascension (Fig. 4). This last limb is close to the trace of the Ascension Fracture Zone and its ridge[19]. The early Tertiary migration may have been controlled by volcanic islands that arose along the ridge.

Brazil to Ascension

We have argued that, since early in the Cainozoic era, the turtle has had an inherited tendency to swim a particular travel path, roughly WNW–ESE. This path can be followed by using the rising sun as a beacon to stay on latitude, an operation made simpler by the fact that the path is equatorial and the migration period is seasonal; turtles arrive at Ascension from February until May. Thus, for a December departure from the coast of northern Brazil the turtle heads directly into the rising sun (that is, ESE) and does the same every day. At night it rests below the equatorial current or even drifts eastwards with the counter-equatorial current[5]. The journey takes perhaps eight weeks. Because of the northerly drift of the sun at this time of the year, the general path followed from Brazil towards Ascension will describe a gentle arc, convex to the south, of the sort shown in Fig. 4. The required target is the intersection of the travel path with a plume of sensory clues arising from the island. Because of the equatorial current, which at this latitude has a southerly component, the stream line of solubles released from the island is favourably disposed to make the intersection and provide the turtle with a pathway to landfall; the stream line gives a longitudinal fix. The equatorial current also serves another important function, that of carrying the hatchlings, imprinted to Ascension, away from the ecologically unsuitable island[5]. The same requirements probably existed for the early Cainozoic populations, when the separation between Africa and South America was insufficient for development of an equatorial current. Reconstructions of late Cretaceous current systems[22] allow us to postulate an equally favourable smaller current system which would perform the same functions during the early stages of the migration to the islands.

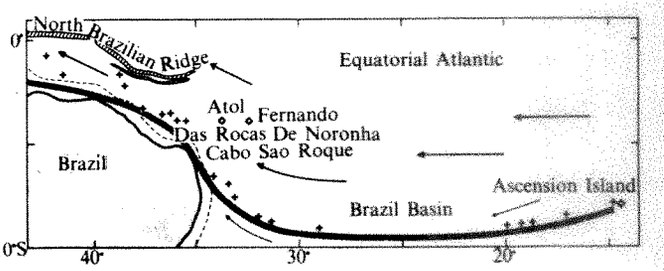

Fig. 4 The western equatorial Atlantic. The arrows indicate the generalised direction of the Equatorial Current (for the northern hemisphere summer). A possible line of seamounts (there are others) is indicated by the vertical crosses. Linking these is a hypothetical migration path (heavy pattern, still to be tested) taken by the Ascension turtles from Brazil to Ascension Island.

This navigatory scheme is simpler than that of Koch *et al.* (ref 7). In particular, it calls for a smaller plume from Ascension, in keeping with the size and nature of the island, and allows for recognition of Ascension emanations, as a new element, against the African background or 'noise' with which the equatorial current is loaded (the Congo contribution alone is massive). If the sun, in combination with chemoreceptive detection of the Ascension plume, is used as a navigational beacon, there would seem to be a corollary which can be examined: turtles from northern parts of the resident grounds would depart first and those from southern parts (south of Recif) would depart later. This is a necessary consequence of the northerly swing of the sun during the visitation period.

Inheritance of behaviour

We suggest that the process of racial learning is of the repetitive, stepping-stone type, which requires no radical change in behaviour at any point. The hypothesis puts the migration to Ascension Island in an evolutionary framework by allowing selective and adaptive processes to operate over a great period of time. Indeed, the period of time may be too long to be acceptable to some. If we are right it means that an extant species has inherited a vital behaviour pattern from ancestors that lived 40 Myr ago and more. In purely taxonomic terms these ancestral species were different, and perhaps very different, from *Chelonia mydas*. In the face of this somewhat unpalatable notion, we take comfort in the realisation that species are more than flesh and bones, especially bones. For the Ascension Island colony, we accept the seaward migration drive as an inherited feature that predates other morphological features conventionally used in systematics to define taxa at species and genus levels. We also accept the far reaching implications which lie behind this statement and its preamble, but we do not have space to discuss them here.

This article is the result, and therefore an acknowledgment, of the scholarly opportunities given to one of us (P.J.C.) during a year as Visiting Professor at the Hawaii Institute of Geophysics, University of Hawaii, where the Director, George Woollard, gave special help. A.C. received support from the National Science Foundation.

PHYSICAL SCIENCES

Uranium in HR8911

In recent years there has been growing interest in analysing stellar spectra in order to observe *r*-process elements (which are synthesised by neutron capture on fast time scales). Cool Ap stars seem to be the most likely objects to display lines of such elements[1,2]. We report here preliminary results concerning some anomalies in the spectrum, which were obtained during analysis of the Cr-Eu-Sr peculiar star HR8911 (κ Piscium) and which show evidence for the presence of *r*-process elements in this object.

Four Mount Palomar spectrograms of HR8911 were measured, one of which was at 4.5 Å mm^{-1} dispersion, and the spectral lines identified from tracings obtained with a Hilger microphotometer. As only about 2/3 of the spectral lines belonged to common elements of A-type stars, we further examined the unidentified lines in the plate at higher dispersions to search for *r*-process elements. We compared the stellar wavelengths and intensities with those listed by Zeidel *et al.*[3]. It is important to stress that the following results concern a single spectrogram, whereas HR8911 is a spectrum-variable star and cursory inspection of the other plates shows considerable spectral variations. For example, in another plate lines of Fe I 43, usually strong in spectra of A-type stars, are much fainter than in the measured spectrogram.

Of the heavy elements synthesised in *r*-processes[4] the presence of osmium and uranium has been confirmed in our analysis. All unblended Os I lines with intensity greater than 50 in the intensity scale of Meggers *et al.*[5] have been found in the spectrum, together with many blended, and fainter lines, such as those observed in the spectrum of 73 Draconis[6]. Unblended Os II lines have not been observed. Almost all unblended lines of U II with intensity greater than 40 have been found in our spectrogram and the presence of many other blended lines is suspected. In addition, we remark that the two strongest U II lines (λ = 3,859.58 Å and λ = 3,854.66 Å) are unblended and clearly visible in the spectrogram.

Furthermore, there is some evidence for the presence of both neutral and singly ionised platinum in the atmosphere of this star, because the four strongest unblended lines of Pt I and some blended lines of Pt II were observed in the tracings. In addition, the strong Pt II ultraviolet line at λ = 3,551.37 Å is clearly visible in the other plates (10 Å/mm^{-1} dispersion).

Among the other *r*-process heavy elements, we found no lines of gold, mercury, lead and bismuth. There are, however, some lines coincidental with Ir I lines, the strongest at λ = 3,800.12 Å. This is unblended and clearly visible in the spectrogram.

In conclusion, it seems that HR8911 shows evidence for *r*-process elements, so it must be added to those Ap stars in which such elements have already been detected. Thus the complex problem of the origin of Ap stars requires a theory which accounts for the presence of these elements in many objects. The hypothesis of a supernova explosion of a nearby star[7] is an acceptable theory because the nucleosynthesis of the *r*-process elements requires a very high neutron density, such as that found in the interior of a highly evolved star. We notice further that in this case magnetic accretion[8], could have an important role.

Maxwellian relative energies and solar neutrinos

THE solar neutrino discrepancy is now regarded[1,2] as very serious. The general attitude is that the Sun is trying to tell us something but no one is quite sure what. I wish in this note to add to the list of possible *ad hoc* explanations; namely that the scarcity of ^{8}B neutrinos reflects a departure of the distribution of relative kinetic energies from the Maxwellian distribution. I have not been able to calculate a cause of the indicated depletion of the high energy tail of relative energies, so this explanation must be limited to the associated effect.

For an ideal gas (which the solar plasma is not) the Maxwellian distributions of single-particle energies can be shown[3] to be equivalent to a Maxwellian distribution for the motion of the centre of mass of the summed masses multiplied by a Maxwellian distribution for the relative motion of the reduced mass. Thermonuclear reactions are calculated with the last of these Maxwellian distributions. For a gas having long range interactions, such as the solar plasma, the distribution function cannot strictly be obtained in such a simple way. The particles undergo many-body collisions and the energy assignable to a particular pair of particles is not defined. A powerful theory could calculate a distribution of relative energies, but only by projecting out of the total distribution its two-particle projection. The usual argument is that the average Coulomb energy is smaller than the average thermal energy, so that an ideal gas is a good approximation.

Nonetheless we should perhaps be cautious, because the thermonuclear reactions involve improbable high energy fluctuations. For example, in a recent model[4] of the solar centre having $T_c = 14.9 \times 10^6$ K the most effective[3] energy E_o for the pp reaction is E_o (pp) = 4.58 kT, and the reaction ^{3}He (α, γ) ^{7}Be leading to production of ^{8}B involves pairs whose average relative energy is E_o (3, 4) = 17.4 kT — very far out on the tail of the distribution. The power for the Sun comes from energies of a few kT, whereas the neutrinos come from nearly 20 kT; that causes the ^{8}B neutrino flux to be strongly modified if the high energy tail of the two-particle distribution is depleted.

To illustrate these effects I have recalculated the Sun assuming all Maxwellian distributions are multiplied by the same factor $\exp f(E)$, where $f(E)$ is a slowly varying function of energy. I find that the ^{8}B flux from the Sun depends on d^2f/dE^2: if $d^2f/dE^2 < 0$, the ^{8}B flux is reduced and if $d^2f/dE^2 > 0$ it is increased. The findings are most easily discussed by expanding $f(E)$ in Taylor series as $f(E) = \beta_o - \beta_1 E - \beta_2 E^2 + \ldots$ and ignoring higher terms as having negligible importance near E_o. The constant β_o is set by requiring that the distribution function remain normalised, and is a function of β_1 and β_2.

The β_1 term has no physical effect although it might seem to have, since it does seem at first glance to reduce the high energy tail. This would be true at fixed T, but to maintain the Sun's luminosity at its known value, its central temperature would have to be increased sufficiently to counteract the effect of β_1 on the solar power. This increase in T raises the ^{8}B neutrino flux back to exactly the value it had for $\beta_1 = 0$. Thus β_1 may be ignored as having no effect. For the ^{8}B neutrinos to be reduced in a Sun of fixed luminosity, the deviation from Maxwellian must decrease faster than $\exp(-\beta_1 E)$ between E_o (pp) and E_o (3, 4); that is, d^2f/dE^2 must be negative.

Suppose then that $f(E) \approx \beta_o - \beta_2 E^2$ and imagine that β_2 is a small number so that no great violence is done to the distribution. It is convenient to think of $\beta_2 E^2$ as being $\delta(E/kT)^2$, where $\delta = \beta_2 (kT)^2$ is a smallness parameter for the deviation. My calculations show that values in the range $5 \times 10^{-3} < \delta < 10^{-2}$ are adequate to suppress the neutrino flux to Davis's limit[1]. Values of δ in this range would mean that the deficiency in the distribution function is only a few per cent at a few kT, and at $E = 10\,kT$ the rate of change of the distribution function with energy due to the β_2 term is still only 10% of the Maxwellian rate of change. These values of δ entail negligible corrections to the equation of state but large corrections to the ^{8}B neutrino flux.

Using the same[4] unperturbed model of the solar centre, I find that the ratio of PPI completions to PPII + III is

$$[\mathrm{PPI}/(\mathrm{PPII}+\mathrm{III})] \approx 10.36 \exp(117\delta) - 0.25 \qquad (1)$$

and is 10.11 for the unperturbed model. I also calculate that the ^{8}B neutrino flux stands in relation to the unperturbed flux as

$$\frac{\Phi_\nu(^8\mathrm{B}, \delta)}{\Phi_\nu(^8\mathrm{B}, \delta = 0)} \approx 10^{-100\,\delta} \qquad (2)$$

For the two values $\Phi = 5 \times 10^{-3}$ and 10^{-2}, the ^{8}B neutrino flux is reduced by factors of 3 and 10 respectively. The flux of neutrinos from ($e^- + {}^7\mathrm{Be} \rightarrow {}^7\mathrm{Li} + \nu$) is reduced by factors of 1.7 and 3.0 respectively in a straightforward application of equation (1). The ^{13}N neutrino flux, which scales as $\exp(-248\delta)$, is reduced by factors 3.5 and 12 respectively. Thus this *ad hoc* suggestion can substantially lower the neutrino detection rate even for sufficiently small value of δ that its value is otherwise almost inconsequential. The only other major consequence that comes readily to mind is that the equilibrium concentration of ^{3}He at the solar centre will have been increased by the factor $\exp(106\delta)$, which is about 2.7 at $\delta = 10^{-2}$.

These suggestions sound implausible because we are led to believe that the Maxwellian must be correct, even in a non-perfect plasma and even at the level of $\exp(-20)$; but the lack of a positive detection of solar neutrinos by Davis[1] is also implausible. I have been unable to treat the difficult aspects of many-body physics involved, so I write in the hope of more authoritative treatment from others.

I thank many colleagues who have urged me to publish this abbreviated account of a more detailed paper I circulated privately in 1971. This research was supported in part by the National Science Foundation.

Martian lee waves revisited

SEVERAL of the Mariner 9 television frames show standing-wave patterns in the clouds of the Martian atmosphere near surface features of high relief. These lee waves have been interpreted as high level condensation clouds in which the brightness variations are due to a combination of true lateral variations in the local concentration of condensed material and the shadows cast on lower levels by such scattering material. Here I demonstrate that the variation in slope of the mean scattering layer with respect to the local horizontal produces a photoclinometric brightness variation strong enough to explain the data with the invocation of quite modest relief in the cloud deck. Although some lee wave clouds in the later frames of the mission leave no doubt that they are mainly pressure trough condensations, lee wave clouds in the early dust-storm phase of the mission are probably largely the photoclinometric effect of vertical oscillations of approximately 40 m in the lines of flow past land protuberances. One interpretation of this result yields a wind velocity of 92 m s^{-1}.

I was particularly interested in a striking frame we chose for the preliminary report of the Mariner 9 mission[1]; a frame taken with the wide angle camera on orbital revolution No. 18 which showed an approximately sinusoidal brightness variation near the Martian terminator, superimposed on the broader brightness variation due to the angular progression of the Sun with respect to the local vertical. This apparent lee-wave pattern was highly periodic, with wavelength of about 40 km, and a general trend of isophotes running roughly parallel to the terminator. On Earth such patterns would be readily ascribed to the periodic genesis of clouds above the lifting-condensation-level as laminar flow lines rose and fell several times in gradually damped, near adiabatic, harmonic compressions and expansions excited by flow over a promontory of some type. Such an interpretation is readily verified for lee waves observed much later in the mission after the planet-wide dust storm abated[2].

I interpret the earlier lee wave in a different manner, in terms of the sinusoidal deformation in the laminar flow line corresponding to the mean scattering level in the top of the dust storm itself. The reason for this has nothing to do with the implausibility of the condensation cloud hypothesis, but rests on the demonstrability that the required deformation, giving rise to a corresponding brightness variation through a change of orientation of the normal vector to the cloud layer with respect to the solar direction, is extremely modest and therefore ought to be the dominant effect.

The development of inferred topography on the basis of the brightness distribution in the image of a surface exhibiting diffuse reflection, and a knowledge of the quantitative law of light scattering for the kind of surface under scrutiny, has been called photoclinometry by common agreement over the past few years. (The word 'photoclinometry' is due to J. F. McCauley from Greek roots *photos* and *clinos*.) An operational photoclinometric theory adapted to light scattering properties peculiar to the Moon was worked out by Watson[3] several years ago.

As part of the Mariner Mars programme I have been developing a generalised photoclinometric theory for application to Mars. The lee-wave deformation of the top of the dust storm is a test case for that theory, in part because the particular light scattering law is reliably known from the isophotal contours of Mars as seen by Mariner 9 before insertion into orbit[1], and also because the 'surface' in question, as an optically thick cloud top, was devoid of albedo variations. Photoclinometry can be unambiguously applied to the determination of a three-dimensional surface corresponding to a mean scattering level so long as the length over which significant optical thickness develops is small compared to the lateral distance over which significant relief develops (this is considerably less stringent a condition than that such an optically thick distance should be short compared to the actual relief itself). An analytical approximation yielding the most essential information about the relief was developed some time ago and shows what modest relief is actually implied.

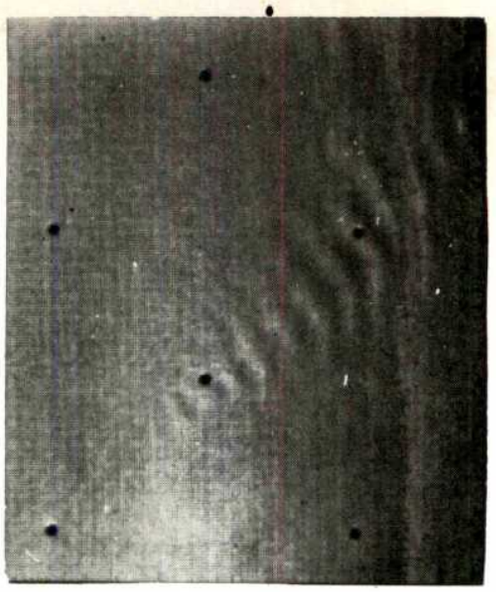

Fig. 1 Lee waves in the top of the great Martian dust storm of 1971, as photographed by Mariner 9. The gradual longitudinal dependence of scattered brightness has been approximately removed, using a computer programme developed by Pat Chavez of the USGS Flagstaff Computer Centre, leaving only the lee-wave effect which may then be greatly enhanced in contrast without partial saturation of the picture.

The planet-wide imagery showed that the planet was very nearly a Lambertian reflector under the dust conditions prevailing at the time. I shall use the Lambertian photometric function, cos i, where i is the incidence angle, in the following analysis. I shall also assume that the quantitative character of the hill and dale wrinkling in the upper dust layers of the Martian atmosphere is truly sinusoidal. Consider such ridge lines running parallel to the terminator and in a longitude interval narrow enough for the angle of the solar direction with respect to the local vertical (not surface normal) to be a constant i_o. If x is a linear distance toward the terminator, then the relative height of the mean scattering level under these assumptions is given by

$$y = A \sin (2\pi x/L)$$

where A is the vertical amplitude of the lee waves and L is the crest-to-crest separation. If i is the angle between the solar direction and the normal to the surfaces of constant dust density in the upper atmospheric layers, then

$$i = i_o + \tan^{-1} (\mathrm{d}y/\mathrm{d}x)$$

If the brightness of the surface is described by $B_o \cos i$, the following brightness variation is derived by simple trigonmetric analysis

$$B_o \cos i = \frac{B_o}{\sqrt{\left[1 + \left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)^2\right]}} \left[\cos i_o - \left(\frac{\mathrm{d}y}{\mathrm{d}x}\right) \sin i_o\right]$$

Obtaining the derivative from the sine wave 'topography', then

$$B_o \cos i = \frac{B_o \cos i_o - \left(\frac{2\pi A B_o}{L}\right) \sin i_o \cos \left(\frac{2\pi x}{L}\right)}{\sqrt{\left[1 + \left(\frac{4\pi^2 A^2}{L^2}\right) \cos^2 \left(\frac{2\pi x}{L}\right)\right]}}$$

The denominator can be neglected for amplitudes up to 2.3 km. In this range the following simple result is obtained for the relation between the total relative contrast and the total relief

$$\Delta B / \langle B \rangle = 2\pi/L \, (\tan i_o) \Delta y_{max}$$

The maximum lee wave contrast is measured in Fig. 1 as 8% at a point where $i = 86°$. The refined ephemeris prediction, which would have placed this point slightly on the dark side of the terminator, was adjusted so that $i = 90°$ occurred just at

zero brightness level. All sources of error considered would probably not change the inferred relief by more than 35%, subject, of course, to the validity of the interpretation. The relief implied by the equation is 40 m.

The basic wind phenomenon at issue does not change under a photoclinometric interpretation. If meteorological parameters are to be inferred in part from image measurements, however, the effects discussed here must be dealt with. One of the simplest meteorological interpretations possible, if use is made of the insignificance of the figure of 40 m. in comparison to the length of the lee waves and the cloud height, is obtained by neglecting the crest-to-trough variations in flow velocity in the Bernouli equation, which is thereby justified. On this view the moving atmosphere can be viewed from a comoving reference frame as an adiabatic oscillator whose expansions and compressions undergo relatively little damping per cycle. The driving force is the buoyancy of the normal atmosphere for vertically displaced cells, from which an oscillator frequency is determined and thus, through the known length of the lee waves, a wind velocity of 92 m s^{-1}. This figure is in fair agreement with other lines of evidence, most notably the sizes of dust particles as inferred from scattering, cloud motions and fluid dynamical considerations, all of which suggest velocities of the order of tens of metres a second. Fuller details will appear elsewhere.

Longitudinal effect in the response of total electron content to magnetic storms

IN a previous study[1] of the response of the ionospheric total electron content (TEC) data to magnetic storms, an average storm time behaviour of TEC for middle latitudes was deduced. On average TEC is enhanced during the first 24 h following the start of a storm, depressed for the next 24 h and near normal through the third 24 h. Another study[2] has shown a strong diurnal component in TEC behaviour with the maximum enhancement occurring in the dusk sector (1600 to 1800 LT). The present study of disturbed TEC behaviour generally agrees with that reported above but in addition indicates a longitudinal effect in the behaviour of both the storm time and diurnal components of disturbed TEC.

Data on TEC for 21 sudden commencement-type storms during 1969 for six viewing stations at middle latitudes are used to compute the average behaviour both in storm time and local time. No distinction is made regarding the severity of the storms used. The averages are computed as a percentage deviation of TEC from the average TEC on quiet days, calculated for each month using data from the ten magnetically quiet days of each month for each viewing station. In computing the averages the data from each storm are weighted to compensate for nonuniform distribution of storm sudden commencements in UT and are adjusted to compensate for deviation of prestorm values of TEC from the quiet day average TEC (ref. 3). I show the results of the storm time behaviour and the local time behaviour for each of these six stations.

The results of the storm time averages are presented in Fig. 1*a* for each of the viewing stations in the order of decreasing westward longitude. The usual initial enhancement in TEC is present in all the data during the first 10 to 15 h after the beginning of a storm. The feature of interest is the second enhancement in TEC which occur between 10 and 30 h after the start of a storm. This second enhancement is almost nonexistent at the easternmost station (Sagamore Hill) but it becomes more pronounced as one moves in the direction of increasing westward longitude (up in Fig. 1*a*). It actually becomes the larger of the two enhancements in TEC at the Stanford viewing station.

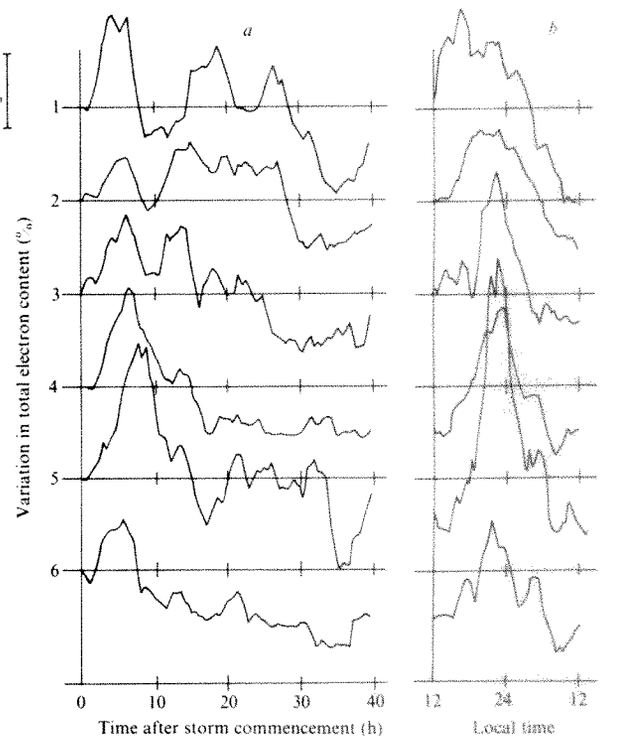

Fig. 1 *a*, Storm time averages of TEC for 21 storms during 1969 given in order of decreasing westward longitude for: 1, Cold Bay (49.8°N, 160.6°W); 2, Stanford (34.6°N, 125.1°W); 3, Fort Collins (37.0°N, 111.5°W); 4, Urbana (37.0°N, 86.6°W); 5, Rosman (32.6°N, 81.9°W); 6, Sagamore Hill (39.3°N, 71.0°W). *b*, Local time averages of TEC for 21 storms during 1969 given in order of decreasing westward longitude for the same stations.

The results of the local time averages are shown in Fig. 1*b*. All the averages show enhancements in TEC occurring during the afternoon and/or evening sectors of the first local time day of the storm. The characteristics of this enhancement also exhibit a longitudinal effect. The westernmost stations tend to have earlier starting and longer lasting afternoon and evening sector enhancements.

These two longitudinal effects are not readily explained by existing storm theories. Some longitudinal variations in the enhancements have been previously reported[4] but these were attributed to the uneven distribution of storms commencements in UT which would in turn result in a difference in the preferred local start times for each station. The weighted averaging used in this study should reduce this effect considerably.

I thank Dr K. C. Yeh and other members of the Ionosphere Radio Laboratory for suggestions and comments. This study was sponsored by the National Science Foundation. The electron content data were collected under a SAMSO Contract.

Strong electric fields above an ordinary rain cloud

ON September 6, 1968, in the course of a balloon flight designed to test our theory[1] that magnetospheric electric fields could be measured at balloon altitudes, we observed electric fields much larger than any we have ever observed in fair weather and which we usually attribute to thunderstorms, during the time that a rainstorm occurred under the instrumentation; however, various observations show that no lightning was being generated within any reasonable distance from our observations.

The apparatus is described in ref. 1; it is a set of three electrometers which measure the potential difference between pairs of conducting plates 2 to 3 m apart. Three orthogonal components of the electric field are measured. The apparatus also carries a magnetometer for measuring orientation and is rotated by a motor at one revolution in 6 min. Conductivity at altitude is periodically determined by momentarily shorting pairs of plates together, then allowing them to recharge through the atmosphere.

The balloon was launched at 2055 local standard time on September 5, 1968 (0255 September 6 UT) and reached its design ceiling of 91,000 feet about 1.5 h later. Usually, drifts in the electrometers are large for 0.5 to 1 h after reaching ceiling, possibly because of contamination of the atmosphere by emission of material from the balloon, but the system was quite well stabilised before the beginning of the observations reported here.

The pertinent observations are shown in Fig. 1. Beginning at 0815 UT all three components of the electric field began a marked change, increasing in magnitude to values which were too large for us to measure. During the onset of this event, at 0817 UT, the horizontal component of the field produced by the cloud (the difference from the pre-storm quiet field) was 150 mV m^{-1} at an azimuth of 30° and the vertical field was also 150 mV m^{-1} above the fair weather value. Data from times during which the conductivity was measured have been deleted from Fig. 1 except at 0945 UT where the recharging can be seen on the vertical field plot.

All components of the field remained off scale for about 1 h, except for occasional switching between the two extreme values of the horizontal measurement range caused either by rotation of the instrument or by field variations, and then

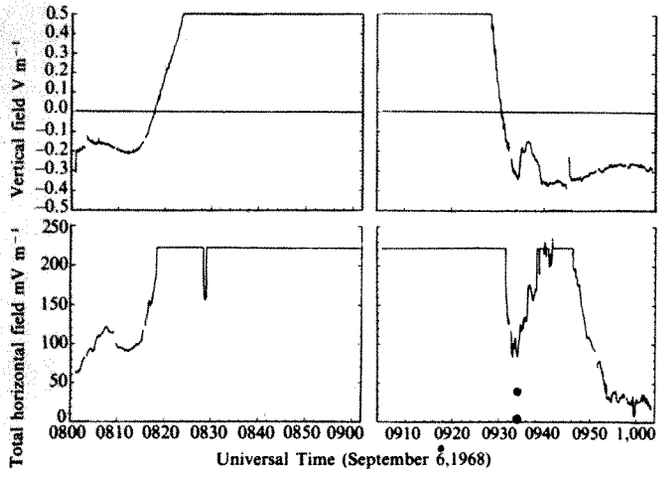

Fig. 1 Electric field variations detected by the balloon-borne instruments.

the field values returned to their 'normal' values over a period of 10 to 20 min. We believe that this phenomenon of switching establishes conclusively that the measurements are real and not the result of a failure in the instrument. Although the electrometers are mainly independent, they do have a common power supply, telemetry and logic system which conceivably might have malfunctioned. But the facts that the horizontal electrometers switch from positive off-scale to negative off-scale as the payload rotates, that they do this one at a time and not together and that the vertical instrument never switches sign, establish the effect as real. At 0932 UT, during the return to normal, the ratio of excess vertical to horizontal fields was 0.85.

The direction of the strong horizontal fields was determined at nine points in the storm, when one or the other of the horizontal axes switched between its extreme values as each of these axes became perpendicular to the fields (Fig. 2). Six of these points gave fields directed generally southwards and the remaining three points indicated westward fields. At the onset of the storm, the horizontal field pointed north, and at the end the field direction was variable, although from 0945 UT to 0951 UT there was an obvious eastward field. These measurements, as well as the brief resurgence of strong fields at the end of the storm, suggest that more than one charged region was present.

During these observations the balloon remained nearly fixed in position about 60 miles north-east of Minneapolis, at 45° 32′N, 92° 02′W. This position was within easy radar range of the US National Weather Service 10-cm wavelength

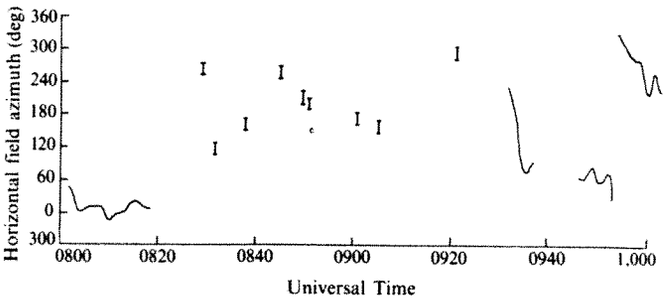

Fig. 2 Horizontal electric field direction.

radar at the Minneapolis—St Paul International Airport and the Weather Service supplied us with the results of their radar observations (Fig. 3). Neither lightning nor thunderstorms were reported within range of the radar in any direction.

Throughout the night, nonetheless, our local v.l.f. monitor recorded strong spheric activity. Observers under the balloon reported no thunder or lightning; thus we attribute the spherics to an intense thunderstorm system that was over the eastern United States at the time, received by means of the enhanced v.l.f. propagation which occurs at night.

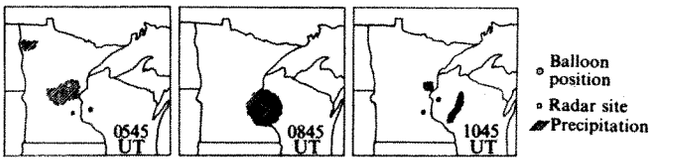

Fig. 3 Precipitation detected by 10-cm radar.

There was, however, a raining cloud some 200 km in diameter, which moved under the balloon when the large fields were observed. The cloud was visible on radar and the balloon recovery team reported rain, as did the tracking team in Minneapolis. The tops of the rainstorm clouds, as reported by radar, were at 18,000 feet. Field-mill measurements from the ground at Minneapolis indicated there was no lightning as the cloud passed overhead (G. Freier, private communication).

Our measurements are consistent with the formation of several bipolar charged regions of the cloud consisting of positive charges located above larger negative charges. The charged condition lasted for about an hour before dissipating.

Conductivity measurements near the end of the storm gave

$$4\pi\sigma = 0.90\ s^{-1}\ (e.s.u.)$$

at the balloon altitude of 27.6 km. This value is in the general range of fair weather values. Using a model of a charged cloud consisting of two unequal charges at different heights, imbedded in an atmosphere with conductivity varying exponentially with height[2-4], we find that typical horizontal and vertical field data may be fitted by an upper charge of 21 C and a lower charge of −35 C, located 50 km from the balloon. With the measured conductivity, the air-earth current due to the storm is 0.12 A.

We conclude that since we have observed strong electric fields above a cloud which did not generate lightning, there must be some process other than lightning which limits charge growth. This work has been supported by a grant from the National Aeronautics and Space Administration.

Possible new effects in solid state physics

IT has been suggested[1,2] that the electric properties of small enough metallic particles will differ in important ways from those of the bulk material. To test such properties Kreibig and Fragstein[3] made nearly spherical silver particles of given radius R, with 30 Å $< 2R <$ 500 Å. This article is concerned with the prediction of new effects which would be observed if particles of similar size consisting of doped and possibly amorphous semiconductors could be produced. The theoretical and experimental background is discussed by Mott and Davis[4].

The simplest example of the effect to be discussed is perhaps activated hopping, for instance in an n-type compensated semiconductor. The disorder can localise the electron states and an activation energy W, provided by interaction with phonons, is necessary for transport. For strongly localised states $W \sim N(E)\ (R_D^3)^{-1}$, where $N(E)$ is the density of states and R_D is the average separation between donors. For typical specimens of interest 100 Å $< R_D <$ 400 Å (ref. 4, page 160) and it may therefore be possible to produce particles such that the particle radius $R < R_D$. In this case $W \sim R^{-3}$ independent of donor concentration. This relationship should be even more easily satisfied in the case of weak localisation, in which case $W \sim (\alpha')^3/N(E)$, where the value of α' is such that $(\alpha')^{-1} > R_D$ (ref. 4 page 41). In this again we should obtain $W \sim (N(E)R^3)^{-1}$. A possible experimental test for such effects is the alternating current conductivity (ref. 4, page 51). The hopping distance R_ω, which makes a maximum contribution at frequency ω, is given by $R = (1/2\alpha) \ln(\nu_{ph}/\omega)$ where α is of the order of the inverse Bohr radius and ν_{ph} is a phonon frequency (ref. 4, page 56). The equation $R = \frac{1}{2} \propto \ln(\nu_{ph}/\omega)$ can be used to define a critical frequency ω_c for ω, such that for $\omega < \omega_c R < R_\omega$ but for $\omega > \omega_c$ $R_\omega < R$. Thus, if $W \sim R^{-3}$ and $\omega > \omega_c$, then $\sigma(\omega) \sim R^6\omega^{0.8}$; whereas for $\omega < \omega_c$, $\sigma(\omega) \sim R^{10}\ \omega$ on the simple theory. This dependence on R and ω could be tested experimentally.

A more dramatic effect seems possible if the current theory of the metal-insulator transition in disordered systems, such as compensated semiconductors, is considered. If the mean square fluctuation of potential is denoted by U_o^2 and J denotes the bandwidth, then the equation $U_o > 5J$ is believed to be approximately correct for localisation (ref. 4, page 26). A distance a_E can be defined such that $U_o = 1/N(E)\ a_E^3$ (ref. 4, page 26). For a given energy, and $a_E > R$ this equation becomes $U_o = 1/N(E)\ R^3$. It follows that for sufficiently small particles the value of U_o will be large enough for the states to become localised so that a metal-insulator transition will occur. The critical value of R will depend on the energy but will be of the order of R_D at the centre of the band. By the same reasoning it is possible that the region of localised states at the edge of the conduction band in amorphous semiconductors will extend over a greater region of energy in small particles.

I thank N. C. Wickramasinghe for pointing out the importance of studying the properties of small particles.

Possible origin of Prandtl's mixing-length theory

PRANDTL'S hypothesis[1,2] about turbulent motion in a simple shear layer proposes that the typical values of the fluctuating velocity components in the x and y directions, u and v, are each proportional to $l\delta U/\delta y$ where l is the mixing length (*Mischungsweg*). Prandtl[2,3] says that l "may be considered as the diameter of the masses of fluid moving as a whole in each individual case; or again, as the distance traversed by a mass of this type before it becomes blended in with neighbouring masses. . . ."; and also that l is "somewhat similar, as regards effect, to the mean free path in the kinetic theory of gases". It follows that the Reynolds shear stress $-\rho_{uv}$ is proportional to

$$\rho l^2(\delta U/\delta y)^2$$

and l is defined so that the constant of proportionality is unity. Prandtl, however, described this expression as "only a rough approximation".

Later work (ref. 4, and see ref. 5 for a summary) has shown that the formula for the mixing-length can be derived, using dimensional analysis, by assuming 'local equilibrium' between the turbulence and the mean flow. The only known example of a region of local equilibrium is the wall layer with $l = Ky$: experimentally $K \approx 0.41$. In a self-preserving (self-similar) flow with a single length scale δ, dimensional analysis gives $l/\delta = f(y/\delta)$. These results of dimensional analysis apply to very restricted cases (which were, however, used historically to test the mixing-length theory) and they have no relation to Prandtl's original derivation. In more general cases the quantity l defined by Prandtl has no simple connection with any meaningful scale of the mean flow or the turbulence.

Almost any method of flow visualisation contradicts Prandtl's idea of momentum exchange via lumps of fluid ('*Flüssigkeitsballen*'). Turbulence is an assembly of tangled vortex lines and sheets, dominated by the essentially three-dimensional phenomenon of vortex stretching. If a lump of fluid happens to move away from its former surroundings as an entity, it interacts strongly with those surroundings by the interconnecting vortex lines.

It seems that Prandtl could reconcile his idea with the results of flow visualisation because the predominant method of flow visualisation used in the early years[2,6] of Prandtl's Institute at Göttingen, during the development of the mixing length theory, was the Ahlborn method—the observation of

particles sprinkled on the free surface of a water flow. Many papers and books in which appear photographs taken at Gottingen show that this method of visualisation is very effective in showing up vorticity normal to the free surface. Indeed, because the free surface acts as a plane of symmetry the vorticity vector is constrained to meet the free surface at right angles. The constraint clearly influences a given eddy to a depth below the surface of the order of the eddy size. It therefore affects all sizes of eddy and not merely the smallest, which contribute most to the vorticity. The three-dimensional character of the turbulence is destroyed near the free surface, leaving only two-dimensional circulations like those seen in, for example, Fig. 36 of ref. 7 (which are similar to the two-dimensional circulations of synoptic scale in the atmosphere, seen in satellite photographs of cloud patterns). The photographs of turbulent channel flow reproduced as Figs 39 and 40 of ref. 7 also show exaggerated two-dimensional circulations, quite unlike our modern concept of turbulent motion but amply justifying the name *Flüssigkeitsballen*: it must surely have been photographs like these that provided the inspiration for Prandtl's mixing-length theory of 1925. In 1934 Prandtl and Tietjens (ref. 7, art. 155) commented that "In the case of a three-dimensional fluid motion, it is necessary to study the flow not only on the surface but also in the interior of the fluid". It is, however clear from their inclusion of free-surface visualisations of turbulence that they did not fully appreciate the untypical nature of the motion in the plane of symmetry formed by the free surface.

It seems very likely that the mixing length concept is a good model for two-dimensional eddying motions like synoptic-scale atmospheric circulations: it should also be applicable to highly stable stratified flows in which vertical motion is suppressed.

These remarks are offered not as a criticism of Prandtl but rather to exonerate him from the criticism that the mixing length concept ignores the facts: it is an excellent description of the flow patterns seen on a free surface. Unfortunately, however, these patterns are not representative of turbulence in the interior of a fluid.

I thank Professors G. K. Batchelor and R. E. Luxton for their suggestions and discussions.

Field evidence relating to the origin of ~ 3,000 Myr gneisses in southern West Greenland

SOME prominence has been given recently to the results and implications of isotope age studies[1–4] in the early Precambrian rocks of the Godthåb region, southern West Greenland. The studies were initiated after field investigations[5] suggested that the Godthåbsfjord region may contain outcrops of the oldest rocks in the earth's crust. McGregor[5] has grouped these rocks into an older and a younger set of gneisses (respectively the Amîtsoq and Nûk gneisses) separated in time by dykes (the Ameralik dykes), metavolcanic and metasedimentary rocks (the Malene supracrustals) and stratiform meta-anorthosites. Among conclusions drawn from the isotope work is that based on initial ratios of $^{87}Sr/^{86}Sr$ that the parents of the Nûk gneisses in the Godthåbsfjord area cannot have been derived by partial or complete melting of the older Amîtsoq gneisses[3]. We wish to comment on the applicability of this conclusion to the Nûk gneisses mapped in the area immediately to the south.

A team from the University of Exeter, supported by the Geological Survey of Greenland and the Natural Environment Research Council, began work in 1972 on the Buksefjorden map sheet (63 V 1, Danish Geodetic Institute), which overlaps the south of the Godthåbsfjord region, (ref. 5, Fig. 17) and the summer of 1973 has seen the completion of 1:20,000 mapping of a coastal area about 15 km wide extending more than 60 km south from Ameralik to Sermilik[6,7] (Fig. 1). Lithological units recognised by McGregor[5] in the Godthåbsfjord region extend south of Buksefjorden and we agree broadly, but not in detail, with the interpretation of the sequence of events in the evolution of the Archaean rocks of West Greenland listed in the most recent publication concerning isotopic ages[4]. It is pertinent to point out that we cannot accept McGregor's terminology[5] in its entirety.

Discordant, but intensely deformed, amphibolitic Ameralik dykes occur in leucocratic Amîtsoq gneisses at granulite and high amphibolite facies on the northeast of Amitsuarssugssuaq and at the entrance to Alangordlia (Fig. 1). The Amîtsoq gneisses and Malene amphibolites in Amitsuarssugssuaq are both injected and variably migmatised by granitic (s.l.) masses and gneisses which in the sense of McGregor are Nûk gneisses. The effect of this injection and migmatisation on the Ameralik dykes is to bring about a progressive loss of coherence until the dykes become strongly attenuated wisps which locally have recrystallised to coarse hornblendites. The wisps ultimately become assimilated by the younger gneisses. The Amîtsoq

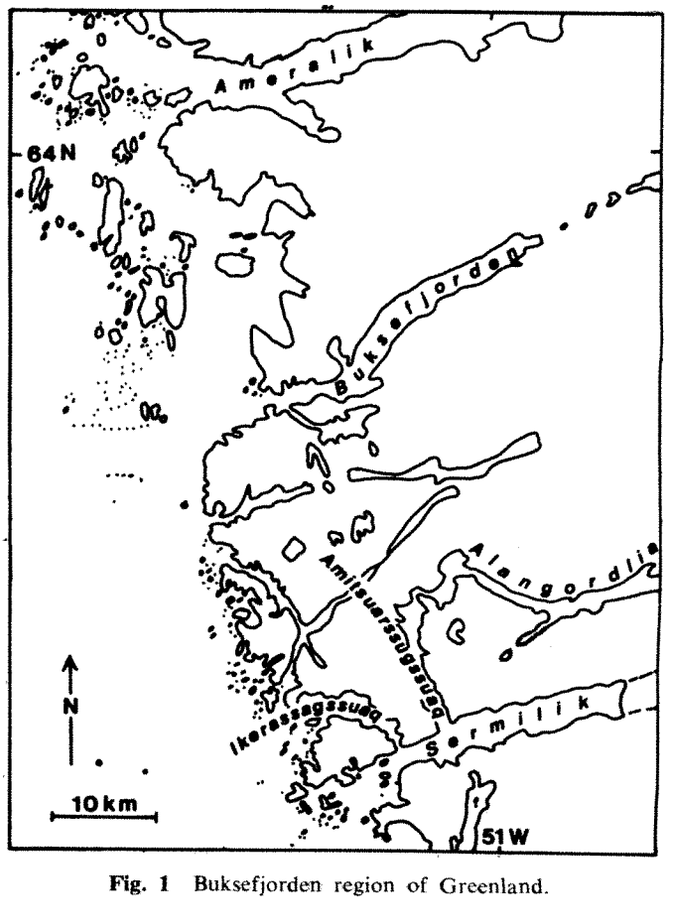

Fig. 1 Buksefjorden region of Greenland.

gneiss host to the dykes is also similarly reduced to xenolithic wisps and schlieren which merge completely into the younger gneiss. Similar effects are visible in coast outcrops around Ikerasagssuaq (Fig. 1). North of this inlet and around Amitsuarssugssuaq, the Amîtsoq gneisses, which for the most part are heavily migmatised with only rare Ameralik dykes, form linear strips within the Nûk gneisses, a relationship which suggests they have peeled off larger areas and are in an interrupted stage of incorporation into newer gneiss. Injected Nûk gneiss also occurs throughout the Buksefjorden region mapped so far. Original igneous textures survive only rarely: a hornblende granodiorite, for example, injected along a boundary between Amîtsoq gneiss and Malene amphibolite in east Amitsuarssugssuaq, retains igneous textures in the north but becomes gneissose with acid ptygma in the south. Much of the Nûk gneiss elsewhere in the Buksefjorden region contains enclaves of Amîtsoq gneiss (some clearly xenolithic) in various states of preservation. Modifications of the younger gneiss and its inclusions to new, banded gneisses have taken place in association with straight belt formation, for example in Amitsuarssugssuaq. This we regard as synchronous with the granulite facies metamorphism which has given a $^{207}Pb/^{206}Pb$ isochron of 2,850±100 Myr. (ref. 4).

The field evidence in the Buksefjorden region shows irrefutably that Nûk gneisses have been derived not only from injected material, but also by substantial remobilisation and incorporation of Amîtsoq gneiss. Our evidence is thus at variance with the conclusions drawn from isotope studies in the Godthåbsfjord region by Pankhurst *et al.*[3], that the Nûk gneisses "cannot have been derived by partial or complete melting of older rocks similar to the Amîtsoq gneisses." It has also been pointed out[4], that Sr and Pb isotope evidence suggests the ~ 2,800 Myr. granulite terrane in West Greenland does not represent a significant reworking of older crust (>100–200Myr.) such as the ~ 3,700 Myr. old gneisses of the Godthåb area, and they conclude that a significant addition of crustal material from an upper mantle source must have taken place in West Greenland between ~ 3,000–2,800 Myr. ago. The fact that Amîtsoq gneisses are common in the granulite facies terrane seen so far in Alangordlia and Sermilik (Fig. 1) does not in our view support this conclusion and we suggest, on the basis of field evidence for the late Archaean tectonometamorphic evolution of the Buksefjorden region to be published elsewhere, that events associated with the granulite facies metamorphism and later intrusion of the Qorqût granite suite[5] and related rocks may mark a stage as significant as the Nûk invasion postulated by McGregor in the addition of mantle-derived material to the Precambrian crust in West Greenland.

Hardening of tungsten carbide by irradiation

We report here a remarkable degree of hardening produced in standard tool-making grades of sintered tungsten carbide in a cobalt matrix by irradiation with charged particles.

Flat, rectangular blocks of three different grades (Wimet H, N and CXT) were bombarded with up to 5 $\mu A\ cm^{-2}$ of 32-MeV ^3He ions in the Birmingham University 150-cm cyclotron. Each block was partially screened by thick aluminium plate which could be moved to expose increasing areas at intervals of 15 min. Each sample was thus divided into 10 separate areas which had been bombarded for periods of 0 to 135 min. The maximum dose given was therefore 1.6×10^{17} ^3He ions cm^{-2} or 3×10^{11} rad. The ions penetrated to a depth of about 140 μm. The temperature of the block did not rise above 400° C during bombardment.

The hardness of each area after bombardment was measured using a Vickers Hardness testing machine, with a pyramidal diamond indentor, a load of 20 kg, and a 17-mm objective lens for measurement of the indentation.

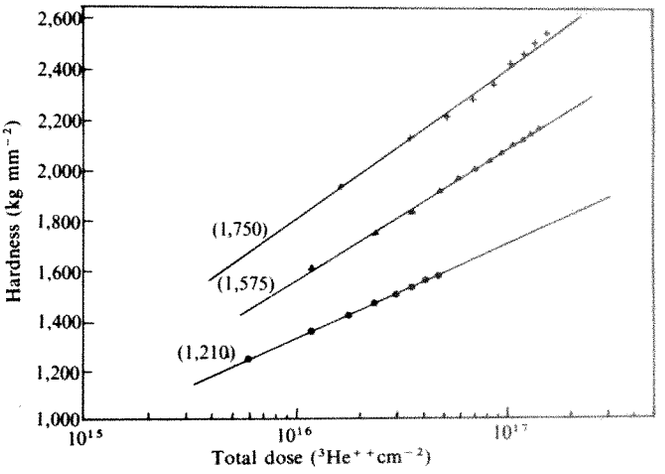

Fig. 1 Variation of Vickers hardness of three grades of Wickman Wimet tungsten carbide with bombardment of 32-MeV ^3He ions. The bracketed figures at the base of each line show the hardness of the unirradiated part of the sample. +, grade H; ▲, grade N; ●, grade CXT (Wickman Wimet grade).

The results are shown in Fig. 1. In the range within which measurements were made the hardness is a logarithmic function of dose, and about 30% increase in hardness was given to the hardest material by a dose of the order of 10^{17} ions cm^{-2}. At this density some 50 or so ions will pass through each atom of tungsten or of cobalt in the surface of the block and extensive damage to the crystal matrix of either material can be expected.

Further details and a more extensive series of measurements, together with measurements of other properties of the irradiated material will be published elsewhere.

We thank Dr E. M. Trent for suggesting the measurement of hardness as an indication of the changes produced by bombardment and for permission to use the necessary equipment; and Wickman Wimet Ltd for providing the samples.

BIOLOGICAL SCIENCES

Activation of maternal mRNA in the absence of poly(A) formation in fertilised sea urchin eggs

THE protein synthesis which follows fertilisation of sea urchin eggs depends largely on genetic templates synthesised much earlier during oogenesis[1]. In the first 2 h after fertilisation the amount of protein being made increases steadily as the preformed mRNA molecules gradually become available for translation[2,3]. During this period of mRNA activation, the polyadenylic acid content of the embryo increases to more than twice the level present in unfertilised eggs[4–6]. This fertilisation-stimulated polyadenylation occurs in the cytoplasm on RNA stored in the egg[6] and is essentially complete by the time of the second cleavage. Soon after fertilisation the poly(A)-containing RNA moves from the post-ribosomal supernatant to the ribosomal-polysomal fraction of embryos[5,6], which suggests that polyadenylation is important in the activation of stored mRNA molecules. This is consistent with other reports that these tracts may play a role in the translation of viral RNAs[7,8] and eukaryotic mRNAs[9,10]. We have therefore investigated whether the formation of poly(A) after fertilisation is necessary for the activation of maternal mRNA. We measured the increase in protein synthesis and active mRNA while poly(A) synthesis was repressed and found a substantial activation even when poly(A) formation could not occur.

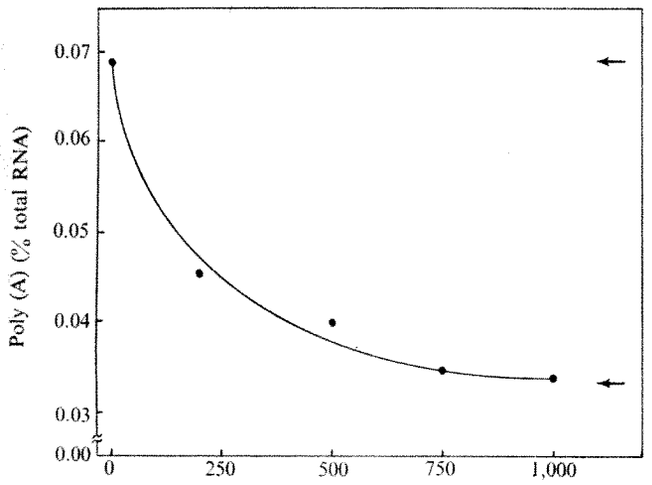

FIG. 1 Inhibition of polyadenylation by 3′-deoxyadenosine. Eggs were collected and washed by conventional procedures and maintained for 1 h on a rotary shaker at 21° C (ref. 2) in artificial seawater (ASW) containing 3′-deoxyadenosine (Cordycepin, Sigma) at the concentration indicated. The eggs were then inseminated with a 1:5,000 final dilution of sperm (95% fertilisation or greater was acceptable) and the embryos were allowed to develop for 2 h, at which time they were in the four-cell stage. Unfertilised eggs and embryos were washed once in cold acid seawater[3], once in a 0.1M Tris-HCl buffer, *p*H 9.0, containing 15% sucrose, and homogenised in 10 volumes of 0.1M Tris-HCl, *p*H 9.0, made 0.5% with sodium dodecyl sulphate[13]. RNA was extracted from the homogenates with phenol and chloroform in a method essentially the same as that used by Slater *et al.*[4] The ethanol-precipitated RNA, redissolved in hybridisation buffer, was washed twice with ether before being measured by $A_{260\ nm}$. The poly(A) content of the RNA was assayed according to the ^{3}H-poly(U) hybridisation technique developed by Gillespie *et al.*[11] and applied successfully to sea urchin RNA by Slater, *et al.*[4] Excellent results were obtained using 10 μg sea urchin RNA per aliquot hybridised with 0.8 μg of commercially prepared ^{3}H-poly(U) (Schwarz/Mann), specific activity 23.6 Ci mol^{-1}. The upper and lower arrows indicate the poly(A) content of normal 2 h embryos and unfertilised eggs respectively.

TABLE 1 Poly(A) assay of *Arbacia* eggs and embryos

RNA	ng poly(U) hybridised per μg RNA	poly(A) (% total RNA)
Unfertilised eggs	0.357 ± 0.041 (8)	0.033
Four-cell embryos	0.739 ± 0.283 (7)	0.069
Four-cell embryos in 3′-deoxyadenosine	0.364 ± 0.054 (3)	0.034
Four-cell embryos in adenosine	0.725 (1)	0.068

The concentration of nucleosides was 1 mg ml^{-1} artificial seawater. Cells were treated and poly(A) content assayed as in Fig. 1. The numbers in parentheses indicate the number of experiments performed.

We assayed the poly(A) in *Arbacia punctulata* using the ^{3}H-polyuridylic acid hybridisation technique of Gillespie *et al.*[11] and observed as reported for other species a doubling of poly(A) between fertilisation and 2 h, when the embryos are in the four-cell stage[4,6]. Further increase was not observed for several hours. Poly(A) formation was inhibited by 3′-deoxyadenosine (Cordycepin), which blocks polyadenylation[4,10,12] by terminating chain elongation. Sea urchin eggs were maintained in artificial seawater containing various concentrations of the adenosine analogue for 1 h, inseminated, allowed to develop in the continuous presence of the drug for 2 h, and assayed for poly(A) content. Increasing concentrations of the drug were found to inhibit the poly(A) formation progressively (Fig. 1), but extensive inhibition required relatively high concentrations. In seawater containing 200 μg 3′-deoxyadenosine ml^{-1}, 67% of the postfertilisation polyadenylation was suppressed; 750 μg ml^{-1} prevented 96% of the increase in poly(A). Similar large doses of adenosine did not affect poly(A) titres (Table 1). Embryos allowed to continue growth in any concentration of 3′-deoxyadenosine up to 1 mg ml^{-1}, although delayed 30–60 min by late cleavage stages, did not arrest until blastula stage. Developmental arrest at this stage is expected since mRNAs transcribed during cleavage seem to be required for gastrulation and morphogenesis[1] and 3′-deoxyadenosine disrupts mRNA formation[12]. It is surprising that such massive doses of the drug did not produce more general toxic effects.

Embryos in which the post-fertilisation addition of poly(A) to the maternal mRNA had been suppressed were tested for their ability to synthesise proteins. After 2 h of development in the inhibitor, they were incubated for

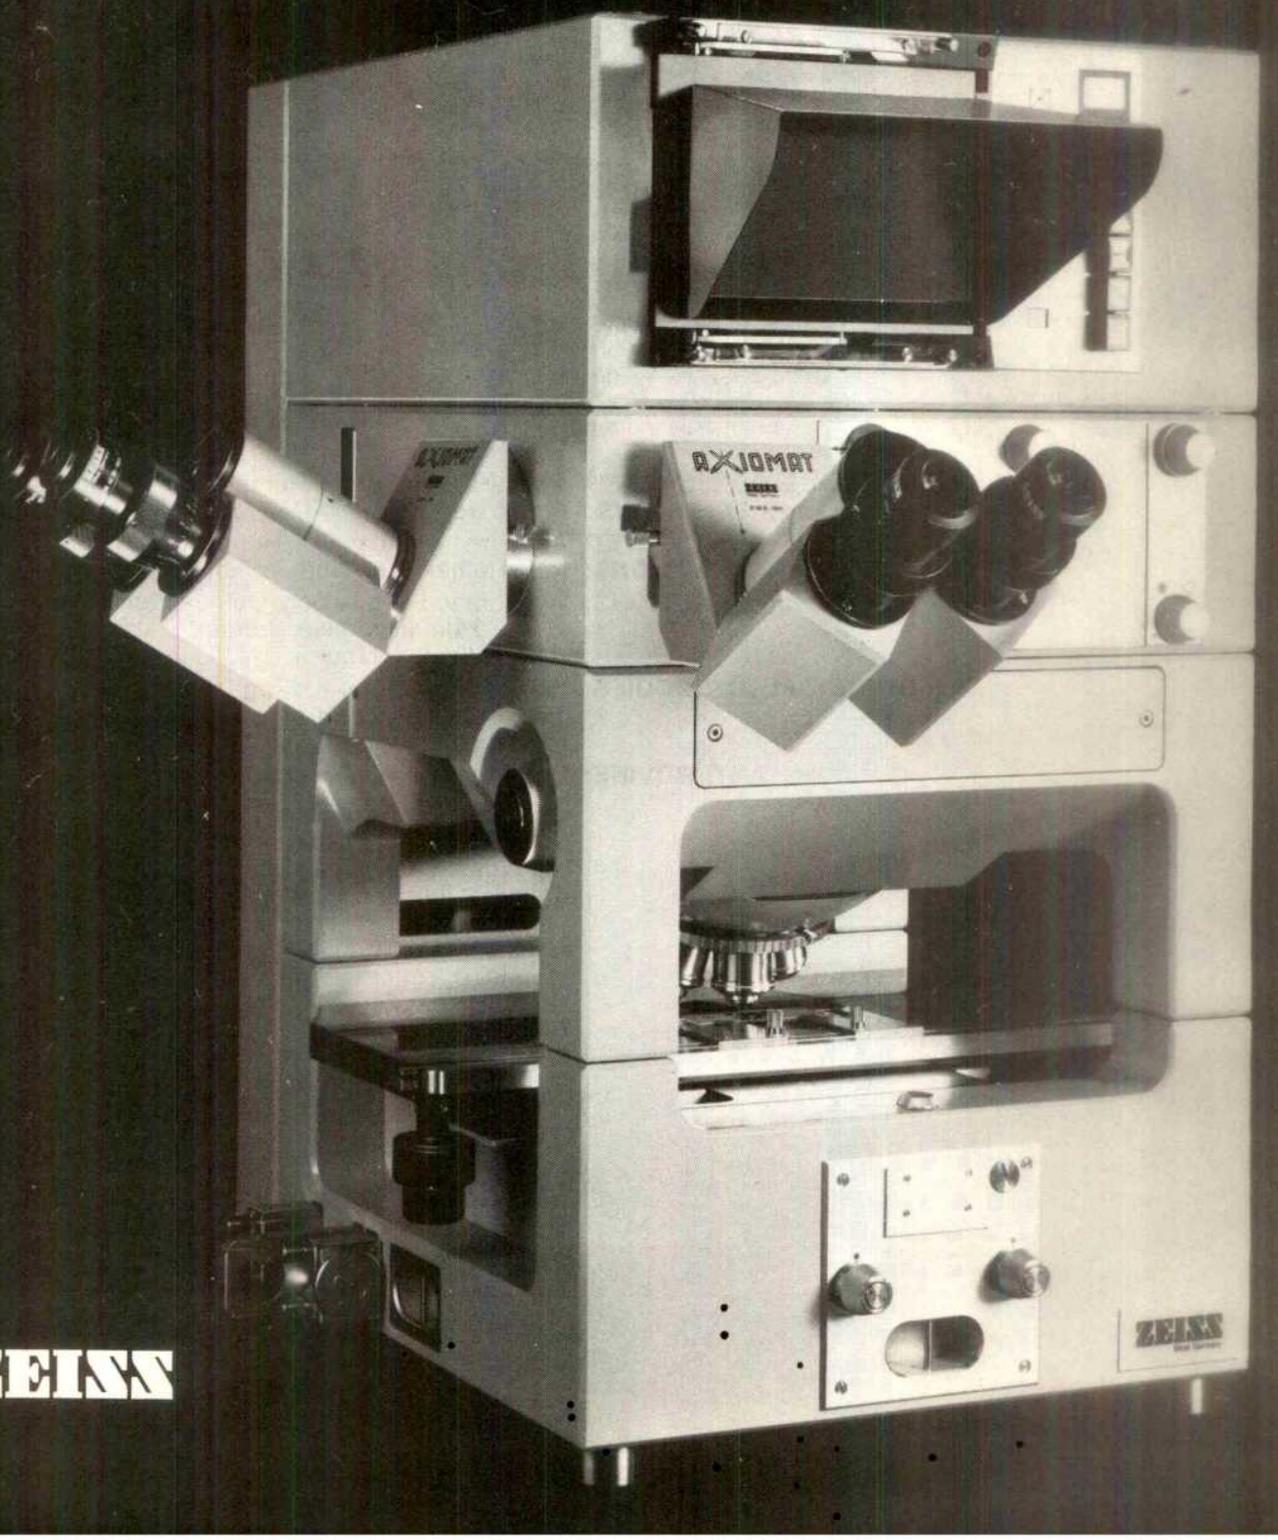
TABLE 2 Protein synthesis in poly(A)-inhibited embryos and controls

Cells	Total incorporation (%)	Incorporation into nascent protein (%)
Unfertilised eggs	6.8 ± 0.03	1.7
Four-cell embryos	31.1 ± 2.9	8.6
Embryos in 3′-deoxyadenosine, 200 μg ml^{-1}	31.9 ± 1.3	9.1
Embryos in 3′-deoxyadenosine, 750 μg ml^{-1}	25.9 ± 2.8	7.4

Cultures of 3 × 10^5 embryos were treated with 3′-deoxyadenosine at the concentrations indicated as described for Fig. 1. Two hours after fertilisation, embryos were incubated for 5 min with 5 μCi ^{3}H-leucine (30 Ci mmol^{-1}). Total soluble radioactivity and radioactivity incorporated into protein was determined by methods described previously[2]. The standard deviation indicated is from three experiments in each case. Incorporation into nascent proteins was determined by preparing polysomes[2,3] from embryos given ^{3}H-leucine as just mentioned and dividing the total radioactivity in the polysome portion of the gradient by the total soluble radioactivity in the sample layered onto the sucrose gradient.

Axiomat

A completely new concept in light microscopy.
Far surpassing anything even Carl Zeiss have done before.



The optics have been completely re-thought, to give more field of view, more zoom, more everything.

The modular design, in four rearrangeable units, gives more stability and more versatility than any previous microscope.

All existing techniques of light microscopy are available and the unique design makes many new ideas possible for the first time.

Come and see it, now being demonstrated at Degenhardt House.

Full details from Carl Zeiss (Oberkochen) Ltd Degenhardt House, 31/36 Foley Street, London W1P 8AP Telephone: 01-636 8050 (15 lines).

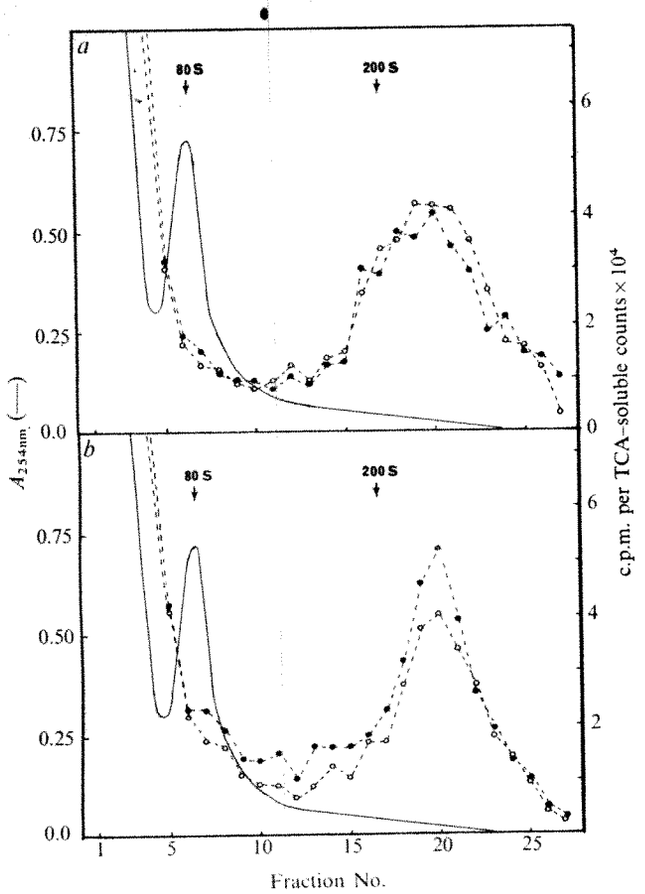

FIG. 2 Comparison of polysomes from normal embryos and embryos grown in 3′-deoxyadenosine at 200 μg ml^{-1} (*a*) and 750 μg ml^{-1} (*b*). A culture of 3 × 10^5 embryos was treated with the adenosine analogue as described in Fig. 1. At 2 h of development, the treated embryos and an equal number of control embryos were incubated for 5 min with 5 μCi ^{3}H-leucine (30 Ci mmol^{-1}). Polysomes were prepared from each culture with a high salt buffer as previously described[2,3] and centrifuged on 30 ml, 10–35% sucrose gradients for 3 h at 22,000 r.p.m. in a Beckman SW25 rotor (5° C). ●, Control embryos; ○, treated embryos.

5 min with ^{3}H-leucine and the rate of protein synthesis was estimated as the percentage of the soluble radioactive pool which had been incorporated into trichloroacetic acid-precipitable protein. This estimate depends on the assumption that the inhibitor does not alter the size of the pool. As Table 2 shows, incorporation at 2 h of development was completely insensitive to 200 μg ml^{-1} 3′-deoxyadenosine, which inhibits two-thirds of the normal poly(A) increase (Fig. 1). Increasing the level of drug to 750 μg ml^{-1}, to produce complete inhibition of the postfertilisation polyadenylation, had only a small effect on incorporation. It seems that protein synthesis can increase after fertilisation even without poly(A) formation.

The activation of protein synthesis when fertilisation takes place involves the translation of additional mRNA, which associates with ribosomes to increase the number of polysomes[3]. The ability of mRNA to enter the polysomes in sea urchins lacking the fertilisation-stimulated poly(A) sequences was investigated by preparing polysomes from the 3′-deoxyadenosine-treated embryos. Polysomes were measured as the percentage of the total soluble radioactive leucine incorporated into nascent proteins during a 5 min incubation with ^{3}H-leucine[2]. There is no diminution in size or number of polysomes from embryos in the adenosine analogue at a concentration of 200 μg ml^{-1}, as compared with polysomes from untreated embryos (Fig. 2*a*). When the dosage was increased to 750 μg ml^{-1} to eliminate all poly(A) formation, polysome size was not affected, although a slight decrease in number of polysomes was apparent in embryos grown in this high level of inhibitor (Fig. 2*b*). The quantitative results of these measurements of nascent proteins on the polysomes (Table 2) confirm the relative insensitivity of the activation of maternal mRNA to suppression of polyadenylation.

Polysomes from 2 h embryos apparently normally contain mRNA which has been polyadenylated as a result of fertilisation[5,6]. Our study suggests however that there is no direct correlation between the addition of these sequences and the ability of the mRNA to form polysomes. The finding that the postfertilisation synthesis of poly(A) is superfluous to the normal activation of maternal mRNA, coupled with the fact that it occurs in the cytoplasm[4,6], raises again the question of a role for poly(A) on mRNA. Evidence is accumulating[5–8,14] that the result of polyadenylation may primarily be the conferral of a higher degree of stability to mRNA during its intracellular transport and translation. The findings presented here are not incompatible with the idea that maternal RNA templates which have been polyadenylated are more stable than those without poly(A).

This study was performed in the Fertilization and Gamete Physiology Training Program at the Marine Biological Laboratory, Woods Hole, supported by a grant from the National Institutes of Health.

Triiodothyronine influences nuclear and extra-nuclear DNA in cultured human kidney cells

THE T-1 cell line, derived from normal human kidney epithelial cells and established over 15 yr ago by van der Veen *et al.*[1], has been found sensitive to and specific for the two thyroidal hormones, thyroxine (T_4) and triiodothyronine (T_3), as manifested by parameters reflecting morphology, proliferation, colony formation, and metabolism of lipids,

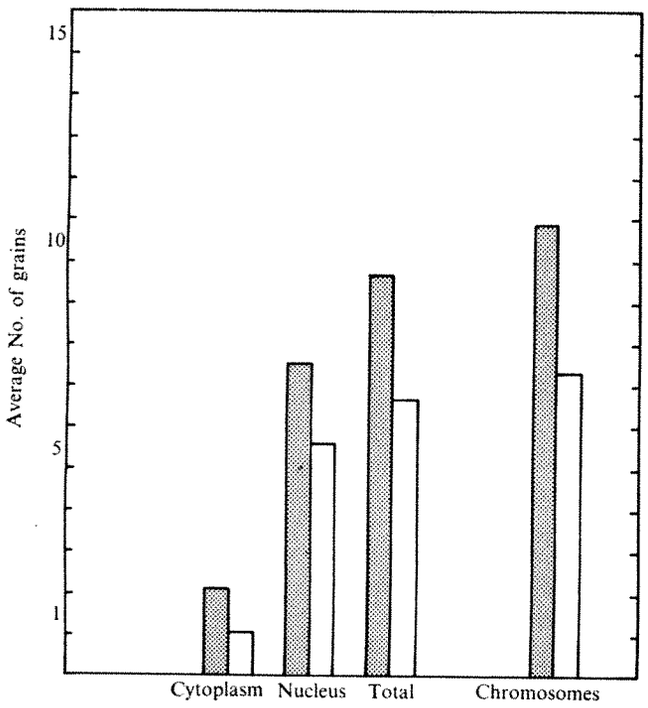

FIG. 1 Results of representative studies of ^{3}H-actinomycin D uptake by triiodothyronine (T_3) stimulated and control T-1 human kidney cells. Approximately 2×10^5 single cells were introduced into 100 mm Petri dishes (in duplicate) containing two microscope slides per dish. Cells stimulated for about 2 d with T_3 (8.90×10^{-7} M) as well as controls were labelled for 20 min with ^{3}H-actinomycin D (specific activity, 6.5 Ci mmol^{-1}) diluted to 0.5 μCi ml^{-1}, before rinsing with Hanks' balanced salt solution (BSS) and fixing with 50% ethanol–Hanks' BSS followed by absolute ethanol. Metaphase spreads of similarly treated and labelled cells were prepared by incubation with colchicine (25 μg ml^{-1}) for 16 h; hypotonic saline treatment and acetic alcohol (1:3) fixation completed the procedure. For autoradiography, cellular preparations and chromosome spreads were covered with Kodak NTB-2 emulsion, exposed for 14 and 11 d, respectively, followed by photographic processing and staining. Plotted are mean grain counts corrected for background, obtained by scoring 400 cells and 200 chromosome spreads; for each determination, the standard error of the mean was less than 5% of the indicated mean. □, control; □, T_3 stimulated.

proteins, and nucleic acids[2–6]. The cultured kidney cells therefore constitute a useful model for studying the peripheral actions elicited by these thyroidal hormones. Previous investigations strongly implicate the nucleus of the T-1 cell as being significantly involved in the response to T_4 and T_3; thus, thyroidal hormones affect nucleolar number, nucleolar RNA, and nuclear uptake of tagged T_4 (ref. 7). Here we report that T_3 acts on DNA throughout the T-1 cell in promoting the localisation of ^{3}H-actinomycin D, a labelled antibiotic that binds specifically to DNA[8,9].

For these determinations, autoradiographs were prepared of T-1 cells to evaluate ^{3}H-actinomycin D uptake by cytoplasm, nucleus, and chromosomes. Routinely, these cultured cells are grown as monolayers in Eagle's MEM supplemented with 10% foetal bovine serum, penicillin and streptomycin in 95% air–5% CO_2 incubators maintained at 37° C. For autoradiography, single cells in the exponential phase of growth, obtained by release and dispersal with trypsin, were overgrown onto microscope slides and, except for controls, stimulated for 2–3 d with T_3 (8.9×10^{-7} M) before tritium labelling; to similarly demonstrate the ^{3}H-actinomycin D associating with chromosomes, metaphase spreads of the labelled T-1 cells were made after incubation with colchicine for 5–16 h. After rinsing, fixing, and covering the slides with photographic emulsion, the exposed and processed autoradiographs were scored by counting developed grains. For making background corrections, autoradiographs of unlabelled preparations were scored. In this manner, cellular ^{3}H uptake was determined (five independent experiments); also assessed was the number of grains associated with chromosomes (three separate experiments). Data derived from representative studies are plotted in Fig. 1.

Evidently, T_3 stimulation of the T-1 cells results in a marked augmentation in binding of tagged actinomycin D, especially to chromatin, as judged by the enhanced nuclear radioactivity of interphase cells and by the label found incorporated in the chromosomes at metaphase arrest. Also noteworthy is the rise in the extra-nuclear localisation of the tagged antibiotic effected by T_3, possibly reflecting interaction between hormone and the mitochondrion[10], a cytoplasmic organelle containing DNA and concerned with respiration and energy transfer.

We wish to thank Ann Yang Kong and Janet A. Weil for technical assistance. This investigation was supported by a research grant from the John A. Harford Foundation, Inc., New York.

Cytochalasin selectively inhibits synthesis of a secretory protein, cellulase, in *Achlya*

IN an effort to elucidate the possible relationship between cytoplasmic streaming and secretion we used the male strain E87 of the water mould *Achlya ambisexualis*[1]. Cellulase secreted by *Achlya* presumably modifies the plasticity of the cellulosic walls of this fungus during morphogenesis[2]. Synthesis of this enzyme can be induced by the steroid hormone antheridiol, by amino acids[2], or by shake induction (mechanical agitation) as reported here. In attempts to arrest streaming we used colchicine and vinblastine, which have been employed to disrupt microtubule function, and cytochalasins, whose reversible effects include inhibition of streaming[3], of macromolecular secretion[4], of uptake of small molecules such as glucose[5], and destruction of microfilaments[6].

Achlya mycelia were grown for 5 d in defined medium[7] aerated by bubbling. After filtration, 1 g of mycelium was incubated in replicates in 10 ml of fresh growth medium lacking glucose. Glucose-free growth medium was used during shake induction, which is not dependent on exogeneous glucose, to avoid the possibility that cytochalasin effects might be due to inhibition of glucose uptake. After 2 h incubation at room temperature on a reciprocating shaker at 120 cycles min^{-1}, 1 ml samples of medium and of aqueous mycelial extract were assayed viscometrically for cellulase using carboxymethyl cellulose as substrate[8]. The aliquot of mycelial

* Glucose-free growth medium, with 2% dimethylsulphoxide, without (−) or with (+) CA at 20 μg ml⁻¹.
† Values represent duplicate treatments.
‡ Mycelial cellulase levels at the start of preincubation were 14.8 and 15.1 units.

extract used for the assay represented 0.5 g fresh weight of mycelium. One unit of cellulase was defined as that amount which gave 1% reduction in the flow time of the enzyme-substrate mixture during a 1 h incubation at 37° C. Cytochalasins (Aldrich Chemical Co., Milwaukee, Wisconsin) were dissolved in dimethyl sulphoxide to give 1% (w/v) stock solutions.

In experiments with *Achlya*, a wide range of colchicine (1×10^{-4} M to 2.5×10^{-3} M) or vinblastine (5×10^{-5} M to 3.3×10^{-4} M) concentrations failed to inhibit streaming or cellulase secretion. Cytochalasin A (CA) inhibited both cellulase secretion and synthesis (Fig. 1). At 20 μg ml⁻¹ cytoplasmic streaming was rapidly and completely arrested. Cytochalasin B (CB) at this concentration failed to inhibit streaming, and its effect on cellulase synthesis ranged from mild inhibition to stimulation. These differential responses to cytochalasins are consistent with those of Betina *et al*[9], who reported that CA, but not CB, is fungistatic and morphogenically active on fungi.

The effects of CA are reversible. Streaming recovers within 30 min of transfer to inhibitor-free medium. Mycelium preincubated for 1 h in CA, then transferred to fresh medium for 2 h of shake induction, is capable of cellulase synthesis and secretion (Table 1). The CA-free controls demonstrate shake induction of cellulase. Mycelium maintained in CA shows little secretion of cellulase, and no increase in tissue

	(1 μg ml⁻¹)	306	60

* All treatments were in duplicate, and contained 1 g fresh weight of mycelium in 10 ml glucose-free growth medium containing 2% dimethylsulphoxide and 0.4 mM leucine. The specific activities of the DL-leucine-1-^{14}C used in experiments I and II were 8.5×10^4 c.p.m. μmol⁻¹, and 7.9×10^5 c.p.m. μmol⁻¹ respectively. The 4 h incubation included 1 h static treatment and 3 h of shaking. Radioactivity was determined using 15 ml of a solubilising liquid scintillation fluid[13]. Medium was sampled after incubation to determine total radioactivity. Mycelia were rinsed twice with 30 ml of unlabelled leucine medium, and ground with sand in 0.5 N NaOH containing 10 mM leucine. The homogenates were acidified with 2 drops concentrated HCl, stored overnight at 0°C, and centrifuged for 15 min at 5,000*g*. Pellets were washed twice with 2 ml 10% trichloroacetic acid containing 10mM leucine, and resuspended in 0.5 N NaOH to a final volume of 2.1 ml. Aliquants were used for liquid scintillation counting, and for protein determination[14]. In *Achlya*, cycloheximide is a known inhibitor of protein, including cellulase, synthesis[12].

enzyme, when compared with the level at the start of preincubation.

The possibility that CA acts as a general protein synthesis inhibitor was excluded by the results in Table 2, which, in agreement with other reports[3,10] show no cytochalasin inhibition of labelled leucine uptake from the medium, or incorporation into protein. Failure of CA to inhibit general protein synthesis in *Achlya* indicates that the selective inhibition of cellulase synthesis may be a secondary effect, resulting from inhibition of secretion.

Previous work using cytochalasins has shown a correlation between streaming and plant cell growth[3,11]. Our results indicate the existence of coupling, not only between streaming and secretion, but between secretion and the synthesis of secretory protein, and raise the possibility that synthesis of certain proteins may be regulated at the level of secretion.

Neurotransmitter synthesis in inner ear and lateral line sense organs

HAIR cells of inner ear sense organs and of lateral line organs in fish are innervated by afferent nerve fibres, to which they transmit information about mechanical stimuli. Efferent inhibitory nerve fibres, which originate in the central nervous system, also innervate most hair cells at their base (Fig. 1*b*). Recent evidence indicates that both these synapses are chemical; excitatory postsynaptic potentials (e.p.s.p.s) have been recorded in afferent nerve terminals in response to mechanical stimulation[1,2] and inhibitory postsynaptic potentials (i.p.s.p.s) have been recorded in hair cells on stimulation of the efferent fibres[2]. Furthermore, several findings suggest that acetylcholine is the efferent transmitter: i.p.s.p.s in hair cells, as well as the ensuing inhibition of afferent discharge, can be blocked by curare[2–5]; both acetylcholine esterase and choline acetyltransferase have been found in the efferent fibres[6–9]. The nature of the afferent transmitter however has not been elucidated, although catecholamines[10] and glutamate[11] have been implicated.

We have investigated possible neurotransmitters in the inner ear and lateral line, especially at the afferent synapse. Three preparations were used: (1) the basilar papilla, an auditory organ in the bullfrog (*Rana catesbeiana*) which has only afferent innervation[12,13] (Fig. 1*a*); (2) the lateral line canal organ of a teleost fish (toadfish, *Opsanus tau*) from which both the afferent and efferent innervations[14,15] have been studied with intracellular recordings[2]; (3) the crista ampullaris of the semicircular canal in the skate (*Raja ocellata*), which has both afferent and efferent innervations and can be used for pharmacological studies.

We used a method based on the finding that cells which use a particular transmitter can synthesise and accumulate this transmitter in high concentrations[16]. Tissues were incubated in a medium containing radioactive precursors of noradrenaline, dopamine, γ-aminobutyric acid (GABA), acetylcholine (ACh) and serotonin. Tissue extracts were then fractionated by high-voltage electrophoresis and the radioactive products were identified[17,18]. The activities of the enzymes involved in the synthesis of particular transmitters were also measured. Preliminary pharmacological experiments were also performed.

Three to eight organs from one of the three types described above were dissected out and incubated at 20° C for 6–18 h in 30 μl of medium (Leibovitz medium for frog (260 mOsmol) and toadfish (320 mOsmol), skate Ringer for skate) containing 100 μCi ml^{-1} of one or a combination of electrophoretically purified L-^{3}H-glutamic acid (generally labelled, 2.5 Ci mmol^{-1}), methyl-^{3}H-choline chloride (6.7 Ci mmol^{-1}) and L-3,5-^{3}H-tyrosine (2.5 Ci mmol^{-1})[17,18]. In two experiments, toadfish lateral line canal organs were incubated with L-methylene-^{14}C-tryptophan (54.5 Ci mol^{-1}). After incubation, the tissue was first washed for 1 min in 2 ml Ringer and then homogenised with a ground glass homogeniser in 20 μl 0.47 M formic acid–1.4 M acetic acid containing unlabelled precursors and transmitters. A 10 μl sample of the homogenate and 10 μl of the labelled medium

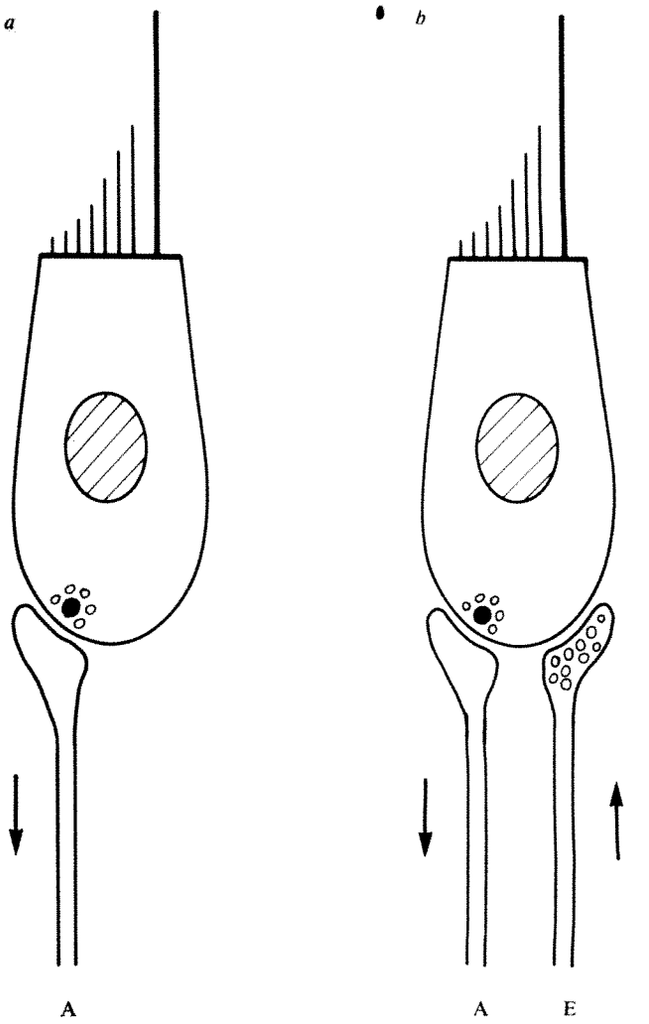

FIG. 1 Schematic diagram of hair cells and their innervation in (*a*) the frog basilar papilla, and (*b*) the lateral line canal organ and the semicircular canal ampulla.

TABLE 1 Biosynthesis of possible neurotransmitters in inner ear and lateral line sense organs

Incubations	^{3}H-Noradrenaline	^{3}H-Dopamine	^{3}H-GABA	^{3}H-Acetylcholine
Frog basilar papillae	30 ± 26	32 ± 18	562 ± 85*	49 ± 15
Frog medium	32 ± 20	35 ± 20	74 ± 39	55 ± 20
Toadfish lateral line organs	30 ± 18	15 ± 9	2,350 ± 340*	556 ± 84*
Toadfish medium	28 ± 15	16 ± 10	122 ± 56	53 ± 27
Skate semicircular canal ampullae	33 ± 22	26 ± 16	1,252 ± 315*	145 ± 45*
Skate medium	30 ± 18	26 ± 16	65 ± 35	26 ± 16
Medium without incubation	29 ± 6	18 ± 8	56 ± 25	28 ± 15

The tissues were incubated in media containing ^{3}H-tyrosine, ^{3}H-glutamate and ^{3}H-choline for 16 h. The numbers represent means ± s.d. of radioactive c.p.m. for 10 μl homogenate or medium for three experiments.
* Value indicates that the synthesis in tissue is significantly different from background.

were used for high voltage paper electrophoresis (6,000 V, 1.5 h, *p*H 1.9)[17,18]. After electrophoresis, the paper was dried, and ascending chromatography was applied perpendicular to the direction of electrophoresis to confirm the identities of the products (solvent for catecholamines and serotonin was: methyl ethyl ketone: propionic acid: water (200:65:55); solvent for GABA and acetylcholine was: *n*-butanol: acetic acid: water (60:15:25))[19]. After chromatography, the paper was dried and the spots corresponding to the precursors and transmitters were revealed by staining[17]. The regions corresponding to the appropriate transmitters and labelled precursors were cut into 1-cm squares and placed in scintillation vials each containing 1 ml 0.01 M HCl. After 2 h, 9 ml of Aquasol was added to each vial and the radioactivity was measured by scintillation counting.

In the basilar papilla and the lateral line canal organ the presence of glutamate decarboxylase (EC 4.1.1.15)[20] and choline acetyltransferase (EC 2.3.1.6)[18] was also investigated. For measurement of glutamate decarboxylase activity, organs were homogenised in 40 μl of L-^{14}C-glutamate (4 μCi, uniformly labelled, 255 Ci mol^{-1}), 2-mercaptoethanol (10 mM), pyridoxal phosphate (1 mM), and KH_2PO_4 (200 mM, *p*H 7.3)[20]. For determination of choline acetyltransferase activity, the organs were homogenised in 40 μl of ^{3}H-acetyl-coenzyme A (4 μCi, 980 Ci mol^{-1}), physostigmine (0.5 mM), KCl (100 mM) EDTA (0.2 mM, neutralised), choline (5 mM) and KH_2PO_4 (10 mM, *p*H 7.2)[18]. Each mixture was divided into four aliquots and incubated at 20° C for 0–8 h. The incubations were stopped by adding 1 μl of 2M HCl to each aliquot. The reaction products were analysed by high voltage paper electrophoresis and the activities of labelled GABA and acetylcholine were measured by scintillation counting.

The experiments on transmitter biosynthesis indicated that the bullfrog basilar papilla with only afferent innervation synthesised GABA but no detectable acetylcholine, dopamine or noradrenaline (Table 1). On the other hand, the lateral line canal organ in the toadfish and the skate ampulla, which have both afferent and efferent innervation, synthesised GABA and acetylcholine but not dopamine, noradrenaline or serotonin. Although quantitative kinetics of enzymatic activities were not studied, our results indicated that the basilar papilla (Fig. 2*a*) contained glutamate decarboxylase but not choline acetyltransferase, whereas the lateral line canal organ contained both enzymes (Fig. 2*b*). These findings are consistent with the results of Table 1.

Thus, acetylcholine was synthesised in the lateral line canal organ and in the semicircular canal ampulla, both of which receive efferent nerve fibres, but not in the basilar papilla which lacks efferents. In addition, choline acetyltransferase was found only in organs with efferent innervation. This correlation strongly supports the notion that the efferent nerve fibres are cholinergic, as suggested earlier by physiological and biochemical[2–9] results. The fact that curare, which specifically blocks cholinergic synapses, abolishes inibition caused by the efferents but leaves afferent synaptic transmission unaffected, implies that a different transmitter is involved at the afferent synapse. Since GABA is synthesised by all three organs, all of which have afferent synapses that show the ultrastructural and physiological criteria for chemical transmission these results point to GABA as a putatitive afferent transmitter.

Our biochemical findings, however, do not exclude the possibility that the synthesis of GABA occurred in the afferent nerve fibres, non-neural elements or other unidentified neurones rather than in the hair cells. In an attempt to clarify this point, preliminary pharmacological experiments were performed on the isolated labyrinth of the skate[21]. In this preparation the horizontal crista ampullaris could be stimulated by hydraulic displacement of the cupula and impulses from single afferent fibres could be recorded for several hours[22]. The base of the ampulla, where the nerve fibres enter, could be perfused with test solutions. Picrotoxin, a specific blocking agent for synapses transmitting with GABA[16,23], was found to block spontaneous as well as evoked discharge in sensory nerve fibres at moderate concentrations of the drug (5×10^{-5} to 10^{-6}M). This blockage was partly reversible in some cases. These experiments will be reported in more detail elsewhere.

Taken together, these findings give support for acetylcholine as the inhibitory transmitter used by efferent fibres of the acustico-lateralis system. In addition, our results raise the possibility that GABA is the neurotransmitter at the excitatory synapse between the hair cell and the afferent fibre. This possibility is interesting because in synapses where GABA has been shown to be the transmitter, its action on the postsynaptic cell is inhibitory[16,24]. Thus, if future experiments substantiate our results, GABA would be an excitatory transmitter used by hair cells in the inner ear and lateral line sense organs.

Release of specific protease during mitotic cycle of L5178Y murine leukaemic cells by sublethal autolysis

SUBLETHAL autolysis is postulated to be the process by which degradative enzymes may modify cell plasma membrane macromolecules without causing cell death[1,2]. Malignant or virally transformed cells can be agglutinated by various agglutinins; their untransformed counterparts are not agglutinated, but normal cells become agglutinable upon mild treatment of the cells with a proteolytic enzyme[3]. Therefore, elevated levels of degradative enzymes may be important for maintenance of the malignant or transformed state through sublethal autolysis, which constantly modifies cell plasma membrane surfaces. This report shows that L5178Y cells release small amounts of a protease active at *p*H 7.8 and that release of this enzyme is almost exclusively in the M period of the L5178Y mitotic cycle. Rubin[4] reported that small amounts of trypsin or Pronase produced an overgrowth phenomenon in cells; that is, contact-inhibited cells were released from contact inhibition and proceeded through a subsequent round of mitosis. Rubin[4] has also isolated from cells infected with Rous sarcoma virus a similar non-dialysable, thermolabile overgrowth-stimulating factor.

The ability of lysosomal enzymes to modify the cell periphery has been documented and the control of cell growth through such modification has been reported[1-6]. Release of lysosomal enzymes during M phase in synchronous normal cells has been reported[3], a proteolytic activity associated with malignant cells mediating fibrinolysis has been said to be a general enzymatic change associated with transformation[7], and increased concentrations of proteases have been found in a number of virally transformed cells compared with their normal counterparts[1,8,9].

L5178Y cells (mouse lymphoma cell line) were grown in suspension culture in sealed containers in Fischer's medium[10] with 10% horse serum and were used in the exponential growth phase. Cell numbers were determined in a Coulter counter. Cells were synchronised by the method of Doida and Okada[11-14] by applying one treatment with excess thymidine followed by one treatment with colcemid and deoxycytidine. At each hour after release from the colcemid block 30 ml cell suspension were centrifuged out of solution at 1500*g* for 5 min, and the medium was assayed for proteolytic enzymes as given below. Simultaneously with the sampling for analysis, 3 ml cells were centrifuged out of solution, resuspended in 0.2 ml Fischer's medium containing 10 μCi of ^{3}H-thymidine (15 Ci mmol^{-1}) and incubated at 37°C for 5 min. The incubation was terminated with 10% trichloroacetic acid; the cell suspension was centrifuged and the insoluble pellet washed twice with 10% trichloroacetic acid and once with ethanol–diethyl ether (2:1 (v/v)) dissolved in 1 M NaOH, plated on a glass filter disk, and counted in a liquid scintillation counter. Counts per minute from zero-time incubations, which were precipitated immediately, were subtracted from these results. This radioactive incorporation of ^{3}H-thymidine is an indication of DNA synthesis in the cell and is a useful measure of synchrony and the S period. Protein was determined by the method of Lowry *et al.*[15]. Crystalline bovine serum albumin was used as a standard. Protein per cell increased linearly from about 0.9 mg per 10^7 cells to about 1.7 mg per 10^7 cells after about 9.5 h and then dropped back to 0.9 mg per 10^7 cells. In general, there was a doubling of the cells at 9.5–10 h after release from the M block. Further details of these methods have been given previously[12-14].

^{3}H-Acetyl haemoglobin was prepared as described previously[15-17]. ^{3}H-Acetic anhydride (400 Ci mol^{-1}) was reacted

* Dissolved in dimethylsulphoxide diluted to 0.8% (v/v) in the assays.

The medium was incubated with the indicated compounds at the final concentration designated for 10 min at 25°C before the substrate was added. Data are given as relative activity; means from five independent determinations.

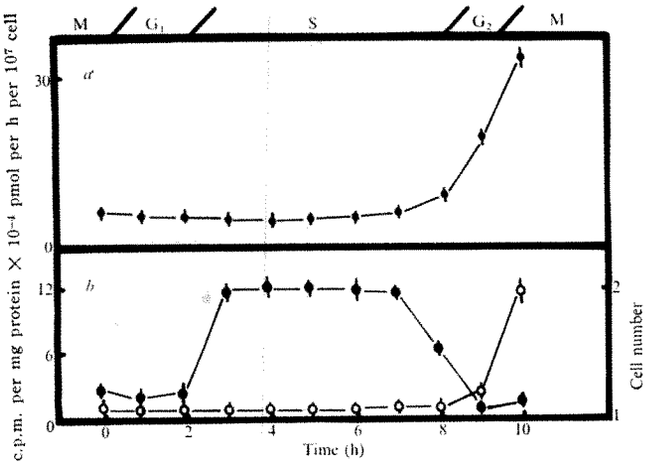

FIG. 1 Activity of released protease in synchronous L5178Y cells. Culture and synchrony of cells was as described previously[11–14]. Experiments were performed by collective cells in the indicated growth phase, removing the cells by centrifugation at 1500*g* for 5 min and analysing the proteolytic activity at *p*H 7.8 of the medium as described in the text. Appropriate medium controls were assayed simultaneously, and the activity was subtracted from the total activity. Data are pmol of ^{3}H-acetyl haemoglobin per 10^7 cells and are means ± 1 s.d. from five independent observations. *a*, Released proteolytic activity. *b*, DNA synthesis during cell mitotic cycle as measured by incorporation of ^{3}H-thymidine into acid-insoluble material (●) and cell number (Coulter counter; ○) in arbitrary units. A representation of the cell cycle is given above the panels[11–14]. Cells were released from mitotic block just before zero time.

with the Type I beef blood haemoglobin. The material was purified to a specific activity of 162 c.p.m. pmol^{-1} based on a molecular weight of 68,000 using the counting procedures described here. The specific activity of the material was 300 Ci mol^{-1}. Routinely in the assay systems described below, 50 μl (136 μg ^{3}H-acetylated haemoglobin; 2 nmol; 324,000 c.p.m.; 0.6 μCi) of the ^{3}H-acetylated haemoglobin was added per assay.

Routinely, 50 to 100 μl of medium or lyophilised medium made up to a smaller volume were added to 100 μl 0.1 M phosphate buffer, *p*H 7.8. As the substrate, 50 μl of ^{3}H-acetyl haemoglobin (2 nmol) were added. This mixture was incubated for 1 h at 37°C in a Dubnoff metabolic shaker. The reaction was terminated by placing the assay tubes in an ice-water bath (0–4° C) and adding 100 μl of 2.5% haemoglobin and 50 μl of 60% trichloroacetic acid (TCA). The precipitated material was removed by centrifugation at 5,000*g* for 5 min, and an aliquot of the supernatant fluid was plated on a glass fibre filter; the radioactivity was determined by counting in a liquid scintillation counter[17,18]. Activity is expressed as pmol of haemoglobin degraded per h per 10^7 cells. Suitable blanks consisting of medium without cells were added and incubated simultaneously.

Medium from exponentially growing L5178Y cells had 8 ± 1 pmol of haemoglobin per h per 10^7 cells. Activity of 5′-nucleotidase, esterase, and UDPase (all enzymes present in large amounts in L5178Y cells[12]) were undetectable in the medium from the same cells, indicating that the proteolytic activity was probably actually released from the cells and that cell lysis was not occurring. The proteolytic enzyme in the medium was very dependent upon *p*H: although a slight peak of activity occurred between *p*H 3 and 4 (2 ± 0.6 pmol per h per 10^7 cells), essentially no activity was present below *p*H 7.0 and above *p*H 8.6. Proteolytic enzymes can be classified in one of four groups: (1) serine proteinases, (2) acid proteinases, (3) thiol proteinases, and (4) metal activiated proteinases[13]. As demonstrated in Table 1, the thiol-specific reagents, iodoacetate and *p*-chloromercuribenzoate, failed to substantially inhibit the proteinase (although the *p*H 7.8 proteinase was inhibited by *p*-chloromercuribenzoate); however, $HgCl_2$ was inhibitory to the enzyme. The data of Table 1 clearly show the released protease to be a serine proteinase.

The data of Fig. 1 show the enzyme to be most active in the M phase of the mitotic cycle; indeed during division at 10 h the enzyme reached peak activity of 30 ± 2 pmol haemoglobin per h per 10^7 cells. The data clearly show that in these chemically synchronised cells a protease active at near physiological *p*H is exclusively released from the cell into the medium just subsequent to and during division. The role this enzyme plays in cellular regulation and control (if any) such as cell division, maintenance of the neoplastic state, overgrowth phenomena, sublethal autolysis, rounding up and lack of adhesion of cells during division, remains to be elucidated.

Exencephaly in the syndrome of trisomy No. 12 of the foetal mouse

EXPERIMENTAL[1] and morphological[2] evidence suggests that exencephaly and anencephaly represent different degrees of severity of cranioschisis. Their morphogenesis seems to involve a primary disturbance of the cephalic somites and notochord. Both conditions are experimentally inducible in several species by the action of different causal factors and teratogens[3–7]. Moreover, exencephaly has been observed occasionally in gene mutants, for example in the mouse[8], though rarely with complete penetrance in the affected strains[9], and apparent autosomal recessive inheritance of neural tube defects has been suggested to occur at least in some instances in man[10,11]. Therefore, it can be assumed that the aetiology of cranioschisis is at least complex and multifactorial involving environmental agents as well as

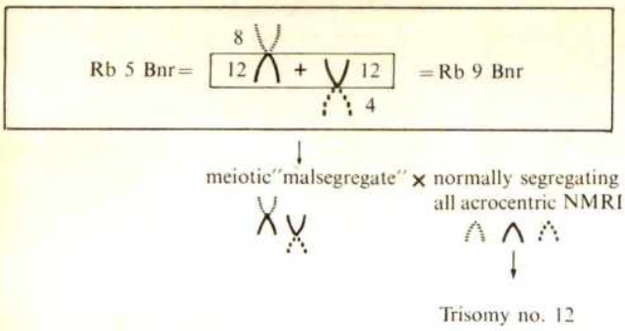

FIG. 1 The breeding of aneuploid zygotes by mating Rb5/Rb9 doubly heterozygous males with NMRI females.

genetic factors. But so far, defects belonging to this entity have not yet been observed in human or other mammalian chromosome mutation syndromes. In this respect it seems of interest to report the finding of exencephaly as constant and characteristic feature of trisomy of chromosome 12 in the mouse foetus.

Double structural heterozygotes possessing two metacentrics derived from Robertsonian changes and displaying monobrachial homology were used for inducing trisomy in the foetal offspring (A. G., D. Giers, and U. K., unpublished). Thus, for the study of trisomy No. 12, doubly heterozygous males with the Rb(8.12)5 and Rb(4.12)9 Bnr metacentrics (refs 12–14 and recommendations of subcommittee to consider rules for chromosome aberrations of the Committee on Standardized Genetic Nomenclature for Mice.) were selected and bred with NMRI (laboratory strain) females (Fig. 1). The two metacentrics share the chromosome arm which corresponds to mouse chromosome No. 12. In meiosis I they form a tetravalent (Fig. 2*a*) which is responsible for anaphase I malsegregation producing 43% chromosomally unbalanced, hypo- and hypermodal (Fig. 2*b*) spermatocytes II (A. G., D. Giers, and U. K., unpublished). On theoretical grounds it can be expected that among the aneuploid zygotes resulting from mating the Rb5/Rb9 double heterozygote with NMRI, the offspring with 41 chromosome arms in which both metacentrics had segregated together must correspond to the trisomy of the arm shared by them, that is of chromosome No. 12 (Fig. 1 and 2*b*).

Nineteen NMRI females mated with Rb5/Rb9 males were killed at day 10, 12, 13 to 14, and 19 (vaginal plugs controlled in the mornings; 'plug day' = day 1). Karyotypes were prepared from the total implant at day 10, and from the foetal membranes in the later stages of which the embryos were saved for morphological studies. At least 10 metaphases per implant were evaluated. At days 10 and 12 to 14, a total of 33 (21%) out of 156 living embryos were aneuploid (Table 1), of which 28 (28/33) showed 41 chromosome arms in the presence of the Rb5 and Rb9 metacentrics. Thus, they corresponded to trisomy No. 12. All of the 13 embryos of days 12 to 14 with the trisomy No. 12 karyotype which were morphologically studied exhibited fully developed exencephaly (Figs 3*b* and 4). The defect of the cranial vault is always complete and the brain protrudes beyond the cranium generally displaying a fairly good differentiation of the telencephalic hemispheres and of the diencephalic and rhombencephalic areas (Fig. 4). The eyes are remarkably small and hypoplastic. The size of most affected embryos is normal or only slightly subnormal. This is also true for the developmental stage characteristics, for instance development of the limbs and of the internal organs. In less than a fourth of the observed cases of cranioschisis, however, the development of the brain was more heavily affected, corresponding to more or less pronounced anencephaly (Fig. 3*c*). In addition these embryos were severely retarded and hypoplastic. At day 19, there were only three cases exhibiting exencephaly and trisomy No. 12, but the affected embryos were already dead and autolysed. A more detailed histological study of trisomy No. 12 describing the changes of the brain, the skull basis, the eyes and other organs, for instance the placenta, will be the subject of a further report.

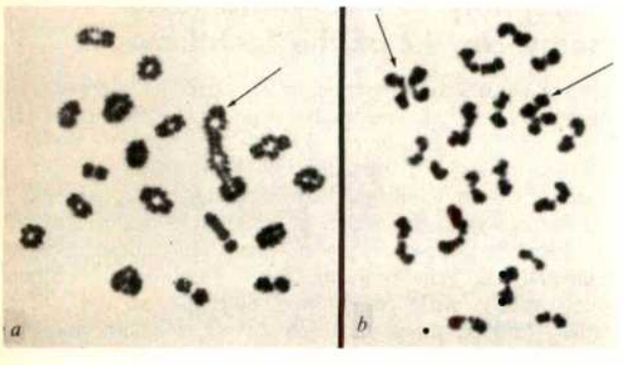

FIG. 2 *a*, Diakinesis (metaphase I) from Rb5/Rb9 male with tetravalent, *b*, Meiotic metaphase II with a hypermodal number of chromosome arms ($n = 21$) in the presence of the Rb5 and Rb9 metacentrics.

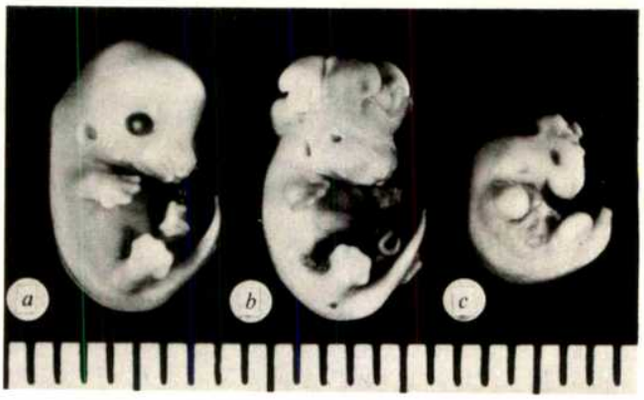

FIG. 3 Three embryos (on mm scale) of backcross progeny Rb5/Rb9Bnr male × NMRI female, day 13½; *a*, normal euploid littermate; *b*, trisomy No. 12 and exencephaly with microphtalmia; *c*, more severely affected and retarded trisomic embryo with anencephaly.

Two trisomic embryos (2/33 of days 10 to 14, one each of day 12 and 14) possessed only one metacentric (Table 1). It has to be assumed that in these cases the extra chromosome cannot be No. 12, but must be the result of meiotic malsegregation of a bivalent, though of undetermined origin. In fact, they were the only morphologically recognisable trisomics without cranioschisis. Their main external feature was marked hypoplasia. Moreover, at day 10, three triploid implants (3/33) were observed, all of them of maternal origin of the extra haploid set.

The present observations indicate that cranioschisis, and particularly exencephaly, is a constant feature of trisomy No. 12 of the mouse foetus. Exencephaly has never been encountered among the other autosomal trisomic conditions of the mouse so far studied in our laboratory (trisomy No. 1, 8, 10, 11, 13 and 15–17, A. G., D. Giers, and U. K. unpublished), or reported from other laboratories (trisomy No. 19, ref. 15). All these trisomic conditions cause death in the course of early or late foetal development, thus eventually leading to their elimination at least before term. In this respect, trisomy of chromosome No. 12 of the mouse can be well delineated and classified as displaying a characteristic

exencephaly or cranioschisis syndrome compatible with survival until a late period of gestatation, possibly until day 17 or 18. The observation that its developmental profile surpasses at least the survival capacity of trisomy No. 1, 8, 11, 15 and 17 (A. G., D. Giers, and U. K., unpublished) lends support to the assumption that cranioschisis *per se* is not the primary cause of prenatal death in the trisomy No. 12 syndrome of the mouse.

We thank D. Giers and G. Noack, Lübeck, for valuable help, Dr M. B. Cattanach, Harwell, who kindly supplied a breeding nucleus of Rb5Bnr mice, and Professor V. Totovic, Pathologisches Institut der Universität Bonn, for providing laboratory facilities to U. K. This work was supported by the Deutsche Forschungsgemeinschaft.

Phosphorylation of selected serine and threonine residues in myelin basic protein by endogenous and exogenous protein kinases

THERE is considerable interest in phosphoprotein metabolism in the brain and the effects of neurotransmitters on the turnover of phosphate in membrane proteins[1]. Emphasis has been placed on the phosphorylation of proteins of synaptosomal membranes, but in addition myelin comprises a considerable proportion of the total substrate activity for a soluble protein kinase of brain[2]. In the following paper Miyamoto *et al.*[3] show that this kinase, which is stimulated by adenosine 3′, 5′-cycle monophosphate (cyclic AMP), phosphorylates the basic protein of myelin. Besides being a substrate for this soluble kinase the basic protein was found to be phosphorylated by an endogenous kinase of myelin[3]. Carnegie *et al.*[4] demonstrated that a protein kinase from rabbit muscle would selectively phosphorylate certain serine and threonine residues in the basic proteins of rat and human myelin. Soluble protein kinases from brain and muscle seem to phosphorylate similar sites in histones[5]. We present evidence here that the endogenous protein kinase of myelin phosphorylates the basic protein, but not the proteolipid protein, and that the site of phosphorylation by this endogenous kinase is quite different from the site phosphorylated by soluble protein kinase.

Myelin was prepared from fresh bovine spinal cord by a rapid method[6] and stored at −20° C. γ-^{32}P-ATP was prepared[7] with a specific activity of 2500 d.p.m. pmol^{-1}. Protein kinase was prepared from rabbit muscle[8] and detailed conditions for phosphorylation of proteins by this kinase are described by Kemp *et al.*[9]

Myelin (300 μl, 7.5 mg protein) was incubated with 50 μmol HEPES buffer[9] pH 7.5; 29.3 nmol γ-^{32}P-ATP; 10 μmol $MgCl_2$; 10 μmol KF, in a final volume of 1 ml, for 10 min at 37° C. Samples (50 μl) were removed and added to 1 ml of a solution of ATP (100 μM) in 50% trichloroacetic acid. The precipitate was collected on glass fibre disks, washed repeatedly with trichloroacetic acid and ATP solution, and finally with ether.

Other incubations were performed as above but with the

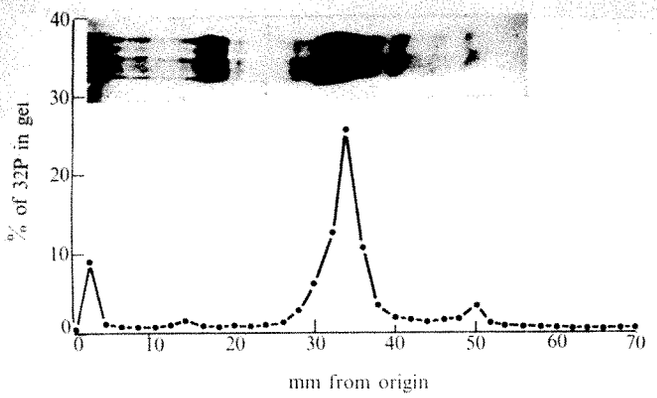

FIG. 1 Electrophoresis of myelin after phosphorylation by γ-^{32}P-ATP and endogenous kinase. Lyophilised myelin (about 10^5 d.p.m.) was dissolved in phenol-formic acid-water (2:1:1, by volume) and separated by electrophoresis in the same solvent in a 15% polyacrylamide gel for 4 h at 550 V. 28 MA. Gels were stained with amido black and 2 mm slices were taken starting from the cathodic side of the slot which is not shown in the photograph of the stained gel. The slices were counted for ^{32}P in a flow counter with an efficiency of 30.8%. Proteolipid protein is the band at 17.5 mm and basic protein that at 34 mm.

addition of either 2 μM cyclic GMP; 2 μM cyclic AMP; or 100 μl of rabbit muscle protein kinase (5.28 mg ml^{-1}) plus 2 μM cyclic AMP. The total ^{32}P incorporated (d.p.m. per mg protein) into the myelin under these conditions were as follows: myelin alone, 3.0×10^5; myelin plus cyclic AMP, 2.8×10^5; myelin plus cyclic GMP, 3.0×10^5; and myelin plus cyclic AMP and rabbit muscle kinase, 4.4×10^5. Thus cyclic AMP did not stimulate the endogenous kinase of bovine myelin. The addition of rabbit muscle kinase increased the total incorporation of ^{32}P into myelin. In other experiments, endogenous kinase did not appear to utilize γ-^{32}P-GTP as a phosphoryl donor.

Phosphorylated myelin was collected from the incubation mixture by centrifugation and washed with 2×10 ml water before lyophilisation. Samples of lyophilised myelin from the above incubation mixtures were dissolved in phenol-formic acid-water (2:1:1, by vol) and subjected to electrophoresis in this solvent[10] in a 15% polyacrylamide gel. Of the total radioactivity applied to gel 25% was not associated with any band of protein but was spread throughout the gel. After correction for this background 85% of the radioactivity was associated with the basic protein and none with the proteolipid protein (Fig. 1). Almost identical patterns, with no additional minor peaks or changes in the proportion (about 9%) of the protein of high molecular weight remaining at the origin, were obtained with myelin from the other incubation mixtures. In the sample with added kinase where the total incorporation of ^{32}P was increased, the pattern remained the same. Approximately 85% of the ^{32}P was incorporated into the basic protein.

Basic protein was prepared from each of the samples of lyophilised myelin by precipitation from chloroform-methanol[11]. The basic protein was collected by filtration and the recovery of radioactivity was similar to that found by gel electrophoresis. Some difficulty was experienced in quantitatively eluting the phosphorylated basic protein from filter paper. That the phosphorylated protein was indeed the myelin basic protein was determined by several criteria. Amino acid analysis agreed with that of a sample of myelin basic protein obtained from bovine spinal cord. Gel electrophoresis showed only traces of proteins other than the myelin basic protein. The main peak of radioactivity coincided with the myelin basic protein and less than 15% was associated with the contaminants, with no individual contaminant containing more than 6%. The phosphorylated proteins were digested with trypsin[12] (treated with N-tosyl-L-phenylalanyl-chloromethyl ketone) for 3 h at 37° C and peptide maps, stained with ninhydrin, were prepared as described in Fig. 2. These maps were identical with those from authentic basic protein.

From the specific activity of the phosphorylated protein approximately 25 mmol P were found to be incorporated per mol of basic protein. Autoradiography for 24 h was used to locate the ^{32}P-peptides. Analysis of the peptides was as described previously[12,4] and phosphoserine was identified by electrophoresis[13]. Myelin basic protein from bovine spinal cord was phosphorylated and digested as previously described for the human and rat protein[4].

The position of the main radioactive spots in a tryptic digest of ^{32}P-basic protein are shown in Fig. 2. The spots are labelled as described by Carnegie *et al.*[4] for the phosphorylated human and rat proteins. Spot A, from these proteins, was not found in the digest of the bovine protein. Spots B, C and F were obtained in sufficient yield for amino acid analysis, which enabled their identification (Table 1). Edman degradation of the material in spot C showed that serine-110, rather than serine-112, was phosphorylated. Spot B was derived from peptide 6 and 7 in the bovine protein. It is well known that acidic residues adjacent to a basic amino acid inhibit tryptic digestion. Spot B was not conclusively identified in the human and rat proteins although it was shown to contain phosphothreonine[4].

Spot G was not obtained in sufficient yield for accurate amino acid analysis. From a comparison of the effects of phosphorylation on the chromatographic and electrophoretic properties of peptides which were identified, however, it was possible to tentatively identify the parent peptides of spots G, K and O. The presence of these spots in digests of phosphorylated bovine, rat and human proteins suggested that they were derived from invariant regions of amino acid sequence[4]. Their low values of R_f and the presence of phosphoserine rather than phosphothreonine in hydrolysates of

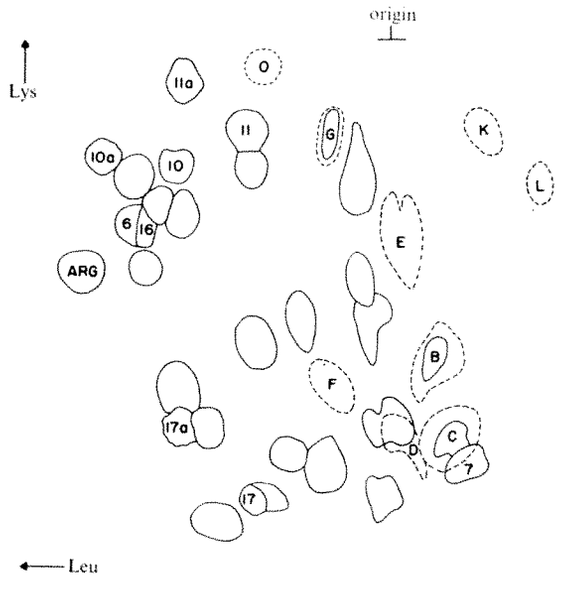

FIG. 2 Peptide map of phosphorylated bovine basic protein. The ^{32}P-protein was digested with trypsin and subjected to electrophoresis at *p*H 6.5 and chromatography in *n*-butanol-pyridine-acetic acid-water (15:10:3:12, by volume)[12]. Peptides reacting with ninhydrin (—) are numbered as in ref. 15 and those labelled 'a' (for example, 10a Arg-Gly-Ser-Gly-Lys) are derived from the failure of trypsin to digest a bond at the N-terminal end of the peptide (for example, 10 Gly-Ser-Gly-Lys). Auto radiography for 24 h was used to detect the ^{32}P-peptides. The main spots (- - - -) are shown and labelled as in ref. 4 as they had identical electrophoretic and chromatographic properties to the corresponding ^{32}P-peptides from phosphorylated human and rat proteins.

TABLE 1 Percentage distribution of radioactivity in peptides from a tryptic digest of ^{32}P-basic protein

^{32}P-Spot (see Fig. 2)	Derived from peptide No. (Fig. 2)	Amino acid sequence	^{32}P-Amino acid residue No. in protein	Incubation mixture with γ^{32}P-ATP: Myelin	Myelin + RMPK + cyclic AMP	Basic protein + RMPK + cyclic AMP

Others	?	Unknown	Ser	9.4	6.8	7.3

Incubations with myelin were carried out for 10 min whereas the incubation of isolated myelin basic protein plus rabbit muscle kinase was carried out for 180 min to enable a direct comparison to be made with the phosphorylation of the human and rat proteins[4]; incubation for 10 min gave a similar distribution.

* Identified by amino acid analysis, and ref. 4.

† Identified by chromatographic and electrophoretic properties (see text). MMA, monomethylarginine; RMPK, rabbit muscle protein kinase. Others, minor spots which had been 0.1 and 3% of the total radioactivity on the peptide map.

these spots eliminated a large number of peptides from consideration. From a comparison of the change in electrophoretic mobility caused by phosphorylation of peptides which were identified, it was possible to estimate the molecular weights of the parent peptides of spots G, K and O (compare ref. 14). After this comparison only two serine residues, 8 and 55, remained to be considered. It is known that trypsin gives rise to three peptides[12,15] all containing serine-55 (Table 1) and these fit the calculated molecular weights of the parent peptides of G, K and O. Therefore, serine-55 was tentatively identified as a site of phosphorylation for the endogenous kinase especially as the sequence adjacent to it is invariant.

Phosphorylation of myelin basic protein by endogenous kinase occurs mainly at one serine residue, tentatively identified as 55 (Table 1). Radioactivity at this site represented 80% of the ^{32}P incorporated. When rabbit muscle protein kinase was incubated with myelin, phosphate was incorporated into serine residues 55 and 110. After allowance was made for the contribution of the endogenous kinase, it seemed that the rabbit muscle kinase was mainly phosphorylating serine-110. These results indicate that the two kinases have different specificities. The labelling pattern obtained with the endogenous kinase was unaffected by either cyclic AMP or cyclic GMP.

As indicated in Table 1, the longer term incubation of the isolated myelin basic protein with rabbit muscle kinase results in phosphorylation of both serine and threonine residues. Miyamoto *et al.*[3] have reported that incubation of isolated myelin basic protein with the brain cyclic AMP-dependent kinase also leads to phosphorylation of serine and threonine residues. It will be important to determine whether the specificity of *in vivo* phosphorylation of myelin basic protein resembles that obtained with endogenous myelin kinase or with exogenously added kinases.

With the isolated bovine basic protein and rabbit muscle protein kinase the distribution of ^{32}P was similar to that obtained with the human and rat proteins except that a major spot A, His-Gly-Ser-Lys, was not obtained with the bovine protein as substrate. The sequence in the bovine protein in this region is -Gly-Arg-Ser-Lys- due to the deletion of His-Gly[15]. No major spot containing this serine was found which may indicate that close proximity of the arginine residue to the serine prevented its phosphorylation. Myelin basic proteins are heterogeneous as a result of methylation of arginine-107 (refs 12, 15). As was found with the human and rat proteins, the rabbit muscle protein kinase preferentially phosphorylated serine-110 in the unmethylated form of the bovine protein[4]. It should be emphasised that this site remains accessible when the protein is complexed with other proteins and lipids of myelin. The accessibility of this region in myelin is supported by preliminary experiments which showed that arginine-107 could be readily methylated by methylase I (G. M. Jones and P. R. Carnegie, unpublished).

In summary, although there are 26 possible serine or threonines available for phosphorylation in the protein, only one of these (serine-55) is preferred by the endogenous kinase and one (serine-110) by the added kinase when the protein is complexed in myelin. Miyamoto *et al.*[3] found the basic protein could be phosphorylated *in vivo* but the sites of phosphorylation have not been identified; it cannot be assumed that they will be the same as those demonstrated *in vitro*.

The observation that the myelin basic protein can be specifically phosphorylated opens up new approaches to the study of the possible physiological role of this protein in normal[16], neurodegenerative[17] and neoplastic[18] conditions.

We thank Mr N. R. Sims for help with the preparation of myelin. We thank the National Multiple Sclerosis Society and the Australian Research Grants Committee for financial support.

In vitro and *in vivo* phosphorylation of myelin basic protein by cerebral protein kinase

A class of cyclic AMP-dependent protein kinases may mediate a wide variety of physiological functions through phosphorylation of enzyme molecules or other cellular proteins[1]. Certain hormones activate these kinases indirectly by causing the synthesis of cyclic AMP in particular organs. The myelin basic protein is a major protein of myelin in vertebrate brains and spinal cords. It has been purified to homogeneity and its amino acid sequence has been established[2,3]. Myelin is a cell membrane substance as evidenced from its ontogenic origin. We wished to know if the basic protein serves as a substrate for a cyclic AMP-dependent protein kinase.

Protein kinase and myelin basic protein were purified from bovine brain according to the method of Miyamoto *et al.*[4] and Oshiro and Eylar[5], respectively.

Myelin basic protein was purified to homogeneity, shown by its migrating as a single band on acrylamide disc gel electrophoresis at *p*H 4.3 (ref. 6). The substrate activity of the myelin basic protein was compared with that of various proteins which are known to be substrates for the protein kinase. As shown in Table 1, ^{32}P was incorporated into myelin basic protein as rapid as into histone, when the proteins were incubated with protein kinase in the presence of ^{32}P-γ-ATP. Dependence of the reaction on cyclic AMP was also clear. Incorporation of phosphate into myelin basic protein was confirmed with gel electrophoresis followed by autoradiography.

The labelled myelin basic protein was hydrolysed in 6 N HCl at 100° C for 4 h to examine into which amino acid residue phosphate was incorporated. The hydrolysate was applied to high voltage paper electrophoresis, and labelled phosphoserine and phosphothreonine were detected. The ratio of phosphorylated serine and threonine residues was 7:9, whereas histone was phosphorylated only at a seryl residue. The phosphorylation of myelin basic protein was inhibited by a modulator of cyclic AMP-dependent protein kinase, as was the phosphorylation of histone[7,8].

TABLE 1 Comparison of phosphorylation of various substrates by cyclic AMP-dependent protein kinase from bovine brain.

Substrate	Amount (μg)	Protein kinase activity (pmol per 5 min per 4 μg enzyme) Without cyclic AMP	With 1 μM cyclic AMP
Histone mixture	200	8.7	79.9
Lysine-rich histone	200	6.3	36.7
Slightly lysine-rich histone	200	4.1	31.7
Myelin basic protein	200	2.4	22.5
Arginine-rich histone	200	2.3	18.9
Casein	500	1.2	6.0
Protamine	500	2.4	4.3
Phosvitin	500	0.5	0.6
Bovine serum albumin	500	0.7	0.8

The phosphorylation of myelin basic protein was proportional to the time of incubation. After 24 h a plateau was reached, with 3.8 mol of phosphate incorporated into the protein molecule, indicating that the protein has four residues which accept phosphate. The extensively phosphorylated protein migrated more slowly, as was expected.

It seemed necessary to prove the *in vitro* phosphorylation of myelin basic protein under more physiological conditions. The myelin fraction was prepared from rat brains according to the method of Uyemura *et al.*[9] and was incubated in the presence of ^{32}P-γ-ATP. Phosphorylation of myelin basic protein by endogenous protein kinase contained in the myelin fraction was demonstrated. Incorporation of phosphate was examined by hydrochloric acid extraction of the basic protein followed by disc gel electrophoresis. Autoradiography and determination of radioactivity in slices of the gel verified the phosphorylation of the basic protein.

We then performed an *in vivo* experiment. We injected 6.1 μCi ^{32}P-orthophosphate into the ventricle of rat brain by the method of Hayden *et al.*[10] The brains were dissected 30 min after the injection and myelin basic protein was purified. Incorporation of labelled phosphate into the protein was demonstrated by autoradiography of disc gel electrophoresis.

The final proof was obtained by the demonstration of the presence of phosphoseryl and phosphothreonyl groups in native myelin basic protein from bovine brain. The contents of the two amino acid residues of the protein was determined by acid hydrolysis and electrophoretic separation of the phosphoamino acids followed by amino acid analysis. Each molecule of bovine myelin basic protein contains 0.07 mol of phosphoserine and 0.09 mol of phosphothreonine residues. The value was calibrated by a partial loss of the phosphoamino acids at acid hydrolysis.

So it is clear that myelin basic protein is present in the brain in a partially phosphorylated form, and we think that the protein is in a dynamic state between phosphorylated and dephosphorylated forms. Methylation and glucosylation of myelin basic protein have been already established. Until now myelin has been considered only as a stable component of neurones, but its function should be reconsidered.

In vitro phosphorylation of myelin basic protein was reported by Dr Carnegie after this study was completed at the 4th International Meeting of the International Society of Neurochemisry. Details of these experiments will be described elsewhere.

The neurogenic and myogenic hypotheses in human (Duchenne) muscular dystrophy

X-LINKED recessive (Duchenne) muscular dystrophy (DMD) is the most common, consistent, and disastrous form of the diseases in man. Evidence that it is neurogenic[1] is open to criticism[2,3]. Though an apparently similar condition in mice, often used as a model, may be neurogenic[4], its different serology[5] and mode of inheritance[6] suggest a fundamental dissimilarity. The following observations on the human disease bring new evidence to bear on the issue.

In mammalian skeletal muscle, each fibre has near its mid-point a single endplate supplied by a single nerve fibre; more than one endplate is a rarity[7–9]. The axon of each lower motor neurone branches repeatedly to supply in this way very many muscle fibres[10] often widely scattered through the muscle[11,12].

If DMD were neurogenic and mediated by the lower motor neurone, then in afflicted males the dystrophic X chromosome in every neurone should render all the musculature dystrophic, as in fact it is[13]. Likewise, in carriers of DMD, the normal early random inactivation as stable[14] sex chromatin of one X chromosome in every female somatic cell[15], including neurones[16], would give an individually proportioned mosaic

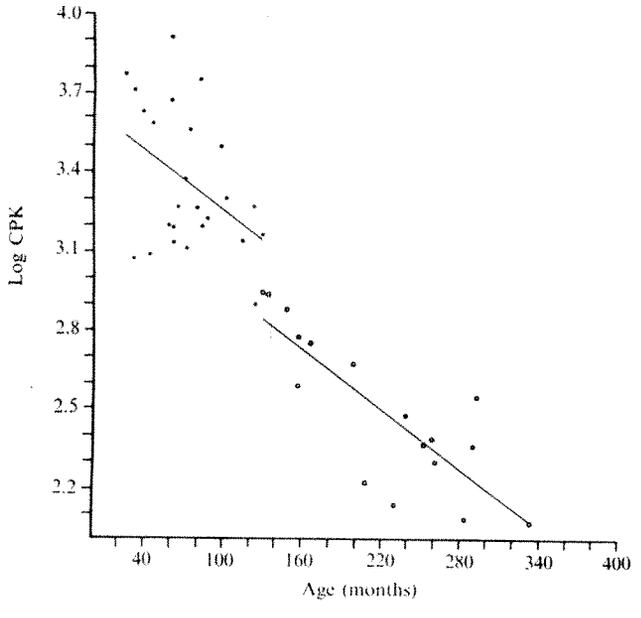

FIG. 1 Linear regressions of log(CPK) on age in sera from boys with clinically classical DMD, showing intercept and slope in equations providing exponential decay rate constant Kd and halflife $t_{1/2}$ of CPK values. Serum CPK throughout is assayed enzymatically[19] and expressed in International Units as mU ml^{-1} at 25° C, with male and female normal upper limits of 58.1 and 37.7 mU ml^{-1} respectively. ●, DMD ambulant: $n = 25$; $y = 3.61886 - 0.003787x$, ($t = -2.22477$ on 33 d.f.; $P < 0.05$), Kd = 0.00872 per month, $t_{1/2} = 79.49036$ months (6.6242 yr); ○, DMD wheelchair: $n = 17$, $y = 3.318915 - 0.0037813x$ ($t = -5.70201$ on 15 d.f.; $P < 0.001$), Kd = 0.008707 per month, $t_{1/2} = 79.61014$ months (6.6342 yr).

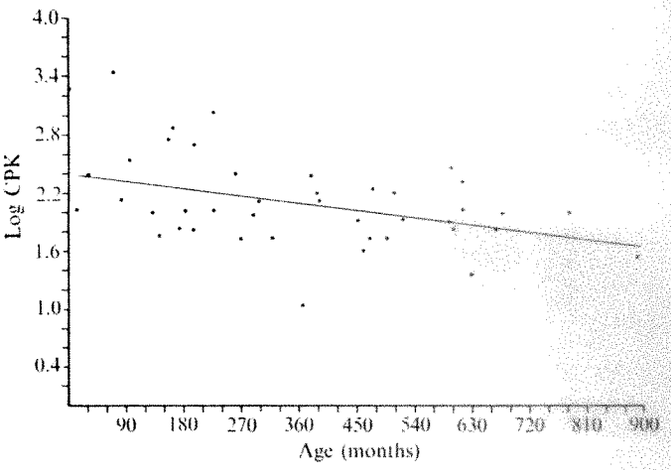

FIG. 2 Linear regression of log(CPK) on age in sera from female DMD carriers positively identified genetically and biochemically[21]. $n = 41$, $y = 2.398989 - 0.000848x$ $t = -2.87954$ on 39 d.f.; $P < 0.01$), Kd = 0.001953 per month, $t_{1/2} = 354.9886$ months (29.5824 yr).

of dystrophic motor neurones governed by the dystrophic X chromosome and healthy neurones by the normal X chromosome. Muscle fibres innervated by the former would then be wholly dystrophic, decaying as quickly as in afflicted males, but healthy if innervated by the latter. Thus carrier muscle should show a dual population of fibres, with clear-cut distinctions between them evident at biopsy. No such distinctions are seen, however. Instead, diffuse general changes are specifically noted[17], and recent electron microscopic findings seem to show all carriers affected[18]. Nor, as we now show, is there biochemical evidence for the expected rapid decay of a population of dystrophic fibres.

In DMD, the easily-measured[19] serum elevations of the muscle-specific enzyme creatine phosphokinase (CPK) due to the disease decline with age as the muscle mass diminishes, and covariance analysis of the data in Fig. 1 shows a constant process in which this exponential rate of decay of CPK is not significantly different between ambulant and wheelchair cases ($F = 0.0004$, 1 and 38 d.f.), with a joint estimate of slope of 0.00379 thus defining the disease. This slope gives estimated intercepts of 3.618 and 3.320 respectively, with a significant difference of about 0.3 ($F = 5.36$. 1 and 39 d.f., $P < 0.05$) implying on taking antilogs that CPK elevations are almost halved on transition from ambulation to the wheelchair. A third determinant is thus apparent, so that CPK in DMD specifically measures active dystrophic muscle mass, and may precisely assess prospective DMD therapy if activity and mass remain little changed over a short period.

In DMD the lifespan rarely exceeds 25 yr, but is apparently normal in carriers. Then if DMD were neurogenic, carriers should show initially a similar steep slope during decay of the dystrophic fibres, becoming horizontal later as in normal women[19]. Figure 2, however, shows a much gentler slope throughout, with covariance analysis giving no significant difference in the slopes before and after 30 yr. Its exponential rate of decline may be due to variable local anatomical disadvantages causing successive disappearance of a small number of fibres throughout life, occasionally evident at biopsy[17]. Its slightness is emphasised by consecutive CPK analyses over 3–7 yr in 22 carriers giving individual slopes neither significantly different from zero nor correlating significantly with initial age; clearly so small an interval with such a slope gives little information. In older carriers, moreover, derivation of probable earlier values from present CPK elevations gives reasonable results (obviously) if the

slope for DMD carriers is used, but unacceptably high values if that for DMD ambulant is used, indicating that wholly dystrophic fibres cannot account for present persistent increases.

Further, the collateral reinnervation by other motor axon sprouts found in denervated muscle fibres[20] has now been described in the fragmenting fibres of DMD[3], particularly in the evolving disease but not in the preclinical or terminal stages, with either minimal alteration or excessive damage. Then on the neurogenic view, if dystrophic carrier fibres decayed as quickly as in DMD itself, proportional reinnervation by adjacent normal axon sprouts and restoration towards normal of some dystrophic fibres should subtract them even more quickly, with a correspondingly more rapid decline of CPK than in DMD. Clearly this does not occur.

These findings and the wide range of sustained manifestation in DMD carriers, from undetectable to markedly abnormal[21], are readily explained by random fusion during early growth of mononucleate myoblasts from clones with one or other X chromosome already inactivated, to give a dual population of nuclei, in different proportions for different individuals, in the mature multinucleated muscle cell[17]. In contrast, a neurogenic view based on orthodox carrier anatomy does not show how the commanding influence of a dystrophic lower motor neurone may be so extensively moderated by a healthy upper motor neurone and other connections, or *vice versa*, to give so wide a range of individually homogeneous carrier manifestation. Nor does it show how in DMD the invariable myocardial involvement, eventually lethal in patients and generally detectable even in carriers[22], occurs without comparable innervation; no such involvement is seen[22] in the putatively neurogenic[23] limb girdle type of muscular dystrophy. The myogenic view of DMD, however, does explain these observations, and if accepted in carriers applies equally to the disease itself in males.

We thank the clinicians who introduced both patients and carriers, and Dr John Shaw Dunn for anatomical discussion. This study was supported by the Muscular Dystrophy Group of Great Britain.

Filaments and ribbons in vertebrate smooth muscle

Since Lowry *et al.*[1] found X-ray evidence for the presence of longitudinally ordered myosin in vertebrate smooth muscle there has been much debate on the precise form in which it is present. Small *et al.*[2,3] have found well ordered and well preserved broad ribbon-shaped elements (80 Å wide and 200–1100 Å broad) in micrographs of vertebrate smooth muscle fixed after relaxation in isotonic and hypertonic salines. They believe that these ribbons are the myosin contractile elements and support this view with the observation that the meridional X-ray reflection of 143 Å (indicative of an ordered myosin structure) could arise from such ribbons.

Choi[4], the first to observe thick filaments in vertebrate smooth muscles, found narrow ribbon-shaped structures in his preparations and so did Fawcett[5]. Many others, however, reported thick filaments in their preparations, either ribbon shaped, polygonal, or circular in cross section[6–14].

Vertebrate smooth muscle myosin is very labile and its demonstration in fixed preparations depends on preparative procedures[13,15], therefore contradictory results were not unexpected and the importance of carrying out all X ray and electron microscopic work in conditions which correspond as nearly as possible to those *in vivo* must be emphasised. We think for the following reasons that work at low temperatures is unsatisfactory, and report studies on muscles relaxed at 37° C.

Lowy *et al.*[1] showed that the 143 Å reflection is best observed in muscles relaxed by cooling, and attributed the increase in intensity of the 143 Å reflection when the muscle is cooled as due only to suppression of movement of cross-bridges upon relaxation[19] but at 0° C, changes in ionic content take place[16] and in particular Ca ions are taken up by the tissue[17] and the myosin appears to have undergone configurational changes[13]. Furthermore, we observe in the electron microscope that when taenia coli is equilibrated in ice-cold isotonic Bülbring-Golenhofen saline[18], as used by Lowy and also by Small, for different periods of time (30 min and 2, 4, 6 and 24 h) and the muscle is then fixed in 2.5% Taab glutaraldehyde buffered with 0.1 M cacodylate buffer at *p*H 7.0, the shape of the thick filaments varies with the period of equilibrium. After 30 min and 2, 4 or 6 h the thick filaments have mixed shapes, narrow ribbons, polygonal or circular as commonly seen with this method of fixation. After 24 h the thick filaments are mainly ribbon shaped (some quite broad ribbons can be observed—up to 770 Å wide) and some cell shrinkage has often occurred.

Like Small *et al.*[2,3] we observe mostly ribbon-shaped thick filaments in taenia coli fixed with acrolein[20] after equilibrating the muscle for only 2 h in ice-cold saline before fixation, probably because acrolein penetrates more rapidly than glutaraldehyde (Fig. 1).

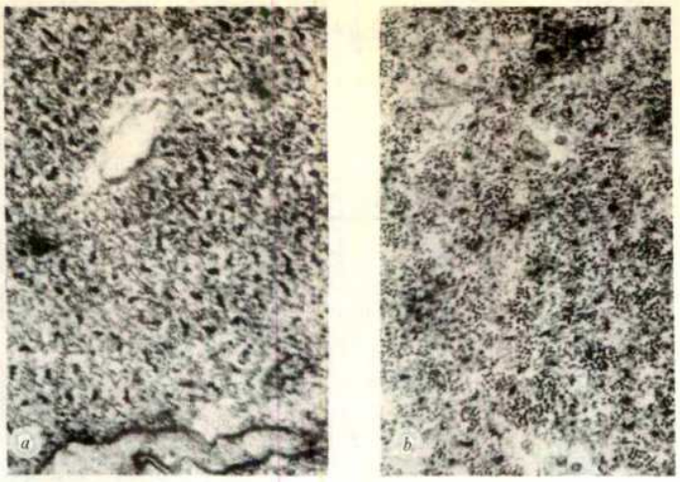

FIG. 1 *a*, Guinea pig taenia coli muscle equilibrated for 2 h in oxygenated Bülbring Golenhofen saline at 4° C. Primary fixation in acrolein[20]. Sucrose was omitted from the fixative. Fixation was followed by an overnight wash in 0.1 M cacodylate buffer, *p*H 7.0, with additional 7% sucrose. Post fixation was in 1% osmium tetroxide dissolved in the washing solution. The muscle was under load throughout equilibration and fixation. Transverse section: note ribbons 80 Å by 320–560 Å (×50,000). *b*, Guinea pig taenia coli muscle equilibrated for 1 h in oxygenated Bülbring–Golenhofen saline at 37° C. The muscle was then relaxed by the addition of xylocaine to the muscle bath (final concentration of xylocaine 1.5 mM). For the primary fixation 5% glutaraldehyde was added to the muscle bath. The muscle was under isometric tension and the tension was recorded throughout equilibration, the addition of xylocaine and primary fixation. Fixation was followed by an overnight wash in 0.1 M cacodylate buffer, *p*H 7.0, with additional 7% sucrose. Post fixation was in 1% osmium tetroxide dissolved in the washing solution. In this transverse section the thick filaments have ribbon shaped, polygonal and circular profiles. 80 Å by 160–320 Å (×50,000).

The size of the ribbons and the degree of shrinkage are very much enhanced if the muscles are equilibrated in cold hypertonic salines and indeed the 143 Å X-ray reflection is usually stronger and much clearer in a hypertonic solution at 4° C than it is in an isotonic solution (Fig. 2).

Also, if a muscle equilibrated for 24 h in the cold is transferred to an oxygenated isotonic saline at 37° C and the tension is recorded, it takes at least 30–40 min for the reappearance of activity and tension development, probably the time necessary for the ion concentration to return to normal and the ribbons to regain their normal shape.

We think therefore that the muscle undergoes considerable changes when it is cooled, and muscles should be studied at normal physiological temperatures (37° C).

Lowy *et al.*[19] relaxed muscles at 37° C by removing calcium from the bathing solution, but such treatment does not make the 143 Å reflection stronger than that of a contracting muscle unless the bathing solution is also made hypertonic (a treatment which enhances the reflection in the cold). We decided to work on muscles equilibrated in an isotonic saline at 37° C and to relax the muscle with a drug if one could be found which did not affect the contractile mechanism of the muscle. The anaesthetic xylocaine (suggested to us by Dr Kiernan of the Health Sciences Centre, University of Western Ontario, Canada) proved satisfactory. When the drug was added to the organ bath in a concentration of approximately 1.5 mM the muscle lost all tension and activity, and showed no sign of activity or development of tension for periods lasting as long as 24 h. If after 24 h the xylocaine was washed away, the muscle recovered normal activity within minutes, suggesting that only the membrane had been affected by the drug. In addition, P. J. Goodford and G. S. Wootton measured the wet weights and the extracellular space of muscles equilibrated in isotonic saline at 37° C with or without the addition of xylocaine and calculated from these measurements that although the cell volume decreased slowly in the control muscles, it stayed unchanged after a slight initial shrinkage in the xylocaine treated tissue. Therefore, in the xylocaine treated material, there is not likely to be an associated effect on the structure of the thick filaments which could affect the X-ray or electron microscope observations.

X-ray diffraction patterns were taken of taenia coli from adult guinea pigs equilibrated at 37° C in oxygenated Bülbring–Golenhofen saline after the muscle had been relaxed by the addition of xylocaine. The X-ray patterns were taken with a mirror monochromator camera on an Elliott G×13 X-ray generator; the tension of the muscle was monitored throughout. At 37° C the 143 Å reflection was not visible in xylocaine relaxed muscles although the actin equatorial reflections and the collagen reflections were good, so we should have seen the 143 Å reflection had it been present: one muscle was cooled to 4° C and the 143 Å reflection did then become visible.

Electron microscope observations were carried out on taenia coli from young guinea pigs (weighing less than 300 g), the muscles were treated in the same way as those used for X-ray observations and when they had relaxed completely after addition of the xylocaine they were fixed by addition of 2.5% Taab glutaraldehyde to the organ bath. The primary fixation which lasted for 1.5 h was carried out at 37° C, washing, post fixation and dehydration proceeded as previously described[14]. Thick filaments were present in many of the cells, but were not always numerous enough to account for all the myosin present in the cells. In cross section an assortment of narrow ribbons, polygonal and circular shapes were observed. (Fig. 1*B*). It has so far not been possible to observe a preponderence of narrow ribbons in cells from muscles after equilibration at 37° C.

Thus, in conditions in which the muscles can contract, when ionic and temperature conditions are appropriate for contraction we can find no X ray or electron microscopic evidence for the presence of broad ribbons.

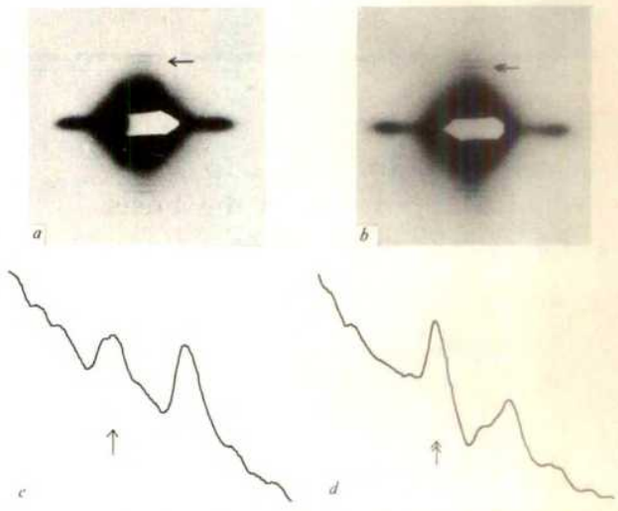

FIG. 2 *a*, X-ray diffraction pattern of a muscle in Bülbring-Golenhofer saline at 5° C; *b*, densitometer trace of part of the meridian of pattern *a*, showing the 143 Å reflection (arrowed) weaker than the adjacent collagen reflection; *c*, X-ray diffraction pattern and *d*, densitometer trace of a muscle in a hypertonic (480 mOsmole) saline solution at 8° C. The 143 Å reflection (arrowed) is stronger than the adjacent collagen reflection. The actin equatorial reflection is much sharper and corresponds to a smaller separation of actin filaments than in the normal saline solution.

We wish to thank Dr H. E. Huxley, Dr P. Lewis and Dr D. M. Needham for valuable discussion during the course of this work.

Production of antibodies to tetrahydrocannabinol as the basis for its radioimmunoassay

TETRAHYDROCANNABINOL (THC) is the main pharmacologically active constituent of cannabis. A sensitive method for its measurement in plasma would be expected to have important clinical, experimental, and forensic uses. Brief descriptions of the production of antibodies to THC have appeared in the past[1–3]. In one case[2], the antibodies were used to bind THC and its derivatives on a quantitative basis involving measurement of the inhibition of antibody fluorescence quenching or enhancement of hapten fluorescence when bound to antibody.

Here we use radioactively-labelled THC to detect the presence of antibodies. Each of six sheep was immunised with a different conjugate of THC and bovine serum albumin (BSA). Five milligrams of conjugate were dissolved in 2 ml of sterile water and emulsified with 4 ml of Freund's complete adjuvant. The mixture was injected intramuscularly into six sites in the medial surface of the thighs of a sheep. Thereafter animals were injected with 2.5 mg of conjugate once a month and bled 7–10 d after each injection. One sheep produced an antiserum capable of binding ^{3}H-THC and this material was investigated further. The conjugate which provoked antibody production was produced by preparation of the chlorocarbonate derivative of THC with phosgene and subsequent coupling of the derivative to BSA by the Schotten-Baumann reaction[4]. By the inclusion of a small amount of ^{3}H-THC in the process, it was shown that an average of 12 haptens were conjugated to each BSA molecule.

^{3}H-THC (2 μCi μg^{-1}) was used to assess the binding capacity of the sheep antisera. One nanogram of labelled THC was incubated for 1 h in a mixture containing a 1:12 dilution of antiserum. The diluent buffer was 0.04 M phosphate, *p*H 7.4, containing 0.15 M sodium chloride and 0.2% bovine gammaglobulin. Separation of the free and antibody-bound fractions of the tracer was effected with 5% uncoated charcoal (UCC)[5]. Aliquots of the supernatant, containing antibody-bound tracer, were taken for β-counting (Table 1).

TABLE 1 Assay protocol

	100%	Zero	Test
Diluent buffer	0.5	0.4	0.4
Normal serum (1:2)	—	0.1	—
Antiserum (1:2)	—	—	0.1
^{3}H-THC (1 ng)	0.1	0.1	0.1
UCC (5%)	—	0.2	0.2

Values indicate volumes in ml. Sera were diluted with diluent buffer. ^{3}H-THC was stored in dioxane and an aliquot diluted with diluent buffer before use. The incubation time was 1 h at 4°C. UCC was 5% charcoal in phosphate-buffered saline.

Table 2 shows the degree of binding of ^{3}H-THC tracer exhibited by 1:12 dilutions of sera collected after successive booster immunisations. The results are expressed as the % of tracer present in the antibody-bound fraction (% bound). With serum taken following the third boost, the decrease in tracer binding produced by increasing amounts of unlabelled THC was measured. Figure 1 shows the calibration curve obtained with a 1:12 dilution of antiserum. The

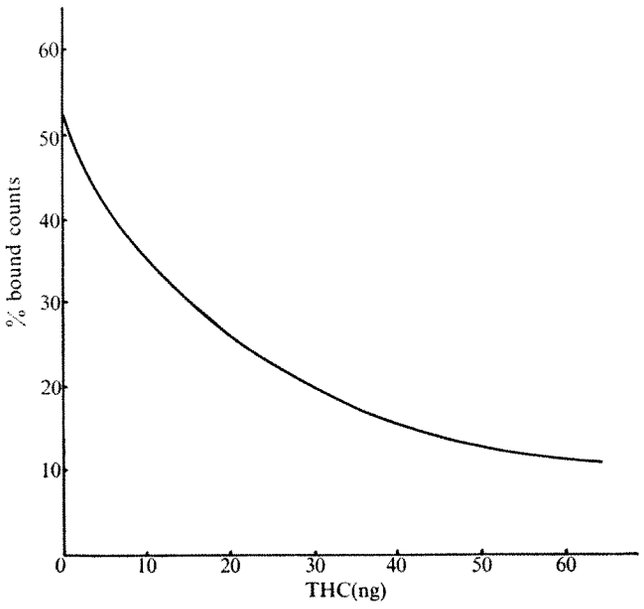

FIG. 1 Inhibition of tracer antibody binding by the addition of increasing amounts of THC to the assay system. The antiserum was used at a 1:12 final dilution and was that obtained following the third booster immunisation. Labelled and unlabelled THC were added simultaneously to the assay system and the incubation time was 1 h at 4° C.

TABLE 2 The ability to bind tracer of 1:12 final dilutions of the sera taken following monthly booster immunisations

Booster	% bound counts
1st	15.2
2nd	21.0
3rd	51.5

smallest amount of unlabelled THC producing measurable inhibition of ^{3}H-THC tracer binding was 2 ng. With higher specific activity tracer, it should be possible to lower the detection limit appreciably. Such a tracer would allow smaller amounts to be used in an incubation system containing less antiserum, and could constitute the basis for an immunological assay for THC with a sensitivity equal to or greater than those of physicochemical methods already in use[6].

This work was supported by the MRC. We thank Dr E. W. Gill for the gift of ^{3}H-THC.

Structural analysis of human proparathyroid hormone by a new microsequencing approach

RECENT evidence indicates that the synthesis of several polypeptide hormones, including parathyroid hormone, involves the production of precursor molecules larger than their corresponding hormones[1–5]. The hormones are generated intracellularly by specific enzymatic cleavage. This process may represent an important control mechanism for hormonal synthesis, cellular storage and eventual secretion of the hormone. Thus complete structural characterisation of both precursor and product molecules for further peptide hormones in several species is clearly desirable. The precursor forms are often present in extremely low concentrations in glandular tissue, however, rendering difficult their isolation and sequence analysis by conventional chemical methods.

We describe here a microsequencing procedure based on automated Edman degradation of internally labelled polypeptides isolated in trace quantities from *in vitro* tissue incubation systems. We used this method, which is about 10,000 times more sensitive than the conventional technique for determination of amino acid sequences[6], to confirm the structure of bovine proparathyroid hormone[7], and then to determine the structure of human proparathyroid hormone.

The bovine and human prohormones of parathyroid hormone were biosynthesised *in vitro* in tissue slices from bovine and human glands. During this process, radioactive lysine, serine, valine, and arginine were incorporated into the prohormone sequences (see Fig. 1 legend for details). These amino acids were chosen because they constitute the residues of the known bovine prohormone-specific hexapeptide. The prohormone fractions were isolated as described previously[1] and sequentially degraded in the protein sequenator.

The results of the sequence analyses are shown in Fig. 1. The sequence of the amino terminal portion of bovine prohormone is the same as that determined by conventional techniques[7]; human proparathyroid hormone contains an amino terminal hexapeptide sequence identical to that of the bovine prohormone. At each cycle of the degradation where an incorporated radioactive residue was released from the prohormone, a clearly detectable, five to ten-fold increase in radioactivity above background was observed. The identity of each residue was confirmed by thin-layer chromatography of the radioactive amino acids removed at each degradation cycle. Approximately 85% of the radioactivity in each aliquot comigrated with the appropriate amino acid–phenylthiohydantoin standards.

We used two controls on the accuracy of the sequence analysis by the radioactive method. First, the analyses were continued for at least twelve cycles to overlap into the bovine and human parathyroid hormone structures already determined by conventional techniques[8–11], where the respective radioactive amino acids were detected in their proper positions (Fig. 1). Second, each cycle of the degradation was monitored for completeness of reaction by using gas–liquid chromatography[12] to measure the molar yield of each residue released from sperm whale apomyoglobin, which was used as a carrier protein in the sequence analyses. By this method each degradation could be shown to have a repetitive yield in the range of 92–94%[13].

Since the additional amino acid residues present in the prohormone-specific sequence are not required for the expression of hormonal activity, one might expect, as with bovine and human proinsulin[4], more amino acid mutations in the prohormone-specific peptide than in the active region or secreted form of the hormone itself. If, however, the proparathyroid hormone-specific sequence, which is identical in human and bovine proparathyroid hormones, is found in other species too, this may reflect constraints in sequence variation which are important for the efficient transformation of prohormone to hormone. Since the sequence of the biologically active region of human parathyroid hormone (first thirty-four residues) is known[10–11], a synthetic peptide[14–15] can now be prepared that comprises the active portion of the human hormone with the additional prohormone-specific hexapeptide added to its amino terminal end. With this peptide, it should be possible to develop a radioimmunoassay for detection of the human prohormone, by techniques used previously with the bovine prohormone[16]. Such an assay should help to delineate the physiological importance of proparathyroid hormone in man.

This highly sensitive microsequencing method represents the culmination of efforts in our laboratory and elsewhere to reduce significantly the quantity of protein or polypeptide needed for structural studies. Conventional non-radioactive Edman methods require at least 100 nmol of starting protein to accomplish a twenty-cycle degradation[13]. Our earlier use of a radioactive coupling reagent, ^{35}S-phenylisothiocyanate, for the automated Edman degradation, reduced the required quantity of protein to 5 nmol[17]. Recently we developed another microsequencing method, the degradation of radioiodinated proteins. The method is useful in determining the position of tyrosine and histidine residues in the sequence of polypeptides, available in only picomole quantities[13]. With the degradation of internally labelled proteins described here,

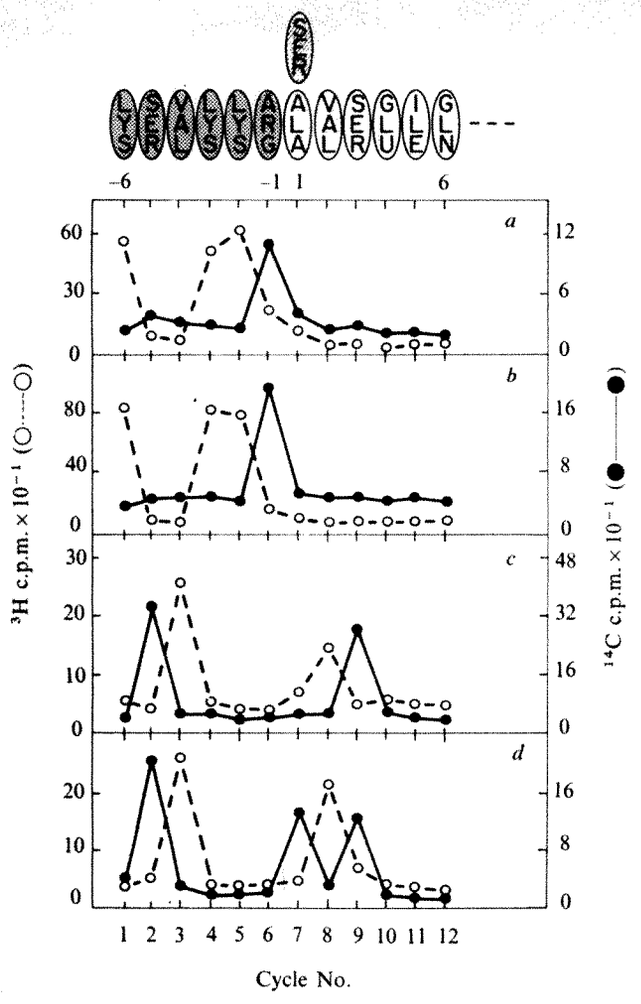

FIG. 1 Sequence analysis of radiolabelled human and bovine proparathyroid hormone. Bovine parathyroid glands were obtained from freshly slaughtered calves, and human parathyroid adenomas came from patients with hyperparathyroidism at the time of operation. Aliquots of about 100 mg of the tissues were incubated for 1 h at 37° C in 2 ml of Earle's balanced salt solution supplemented with 5% foetal calf serum, essential and non-essential amino acids (5 mm) and either a mixture of ^{3}H-lysine (26.8 Ci mmol^{-1}) and ^{14}C-arginine (0.31 Ci mmol^{-1}) or ^{3}H-valine (4.8 Ci mmol^{-1}) and ^{14}C-serine (0.15 Ci mmol^{-1}). The radiolabelled bovine and human prohormones were isolated from the tissue by extraction in 8 M urea–0.2 N HCl and electrophoresis on polyacrylamide gels as described previously[1]. Approximately 0.5 μg (50 pmol) of each of the specifically labelled prohormones containing about 20,000 c.p.m. ^{3}H and 5,000 c.p.m. ^{14}C were isolated by this procedure. The radiolabelled prohormones were dissolved in 0.2 ml of 20% acetic acid, to which 2 mg of sperm whale apomyoglobin was added as carrier protein during automated Edman degradation[6,20]. The prohormones were sequentially degraded for twelve cycles in the Beckman 890 C sequencer using a standard protein program as described by Edman and Begg[6]. A 20 nmol sample of the appropriate unlabelled phenylthiohydantoin amino acids (lysine and arginine or, alternatively, serine and valine) were added to each tube of the fraction collector before the start of degradation to protect against absorptive losses of the trace amounts of labelled amino acids. At the completion of the twelve-cycle degradation, aliquots were taken from each fraction collected and were counted directly in Liquiflour (NEN) in a Packard dual channel spectrometer at a setting which allowed independent measurement of ^{3}H and ^{14}C in the same vial. The remainder of the sample was allocated for thin-layer and gas-liquid chromatography. At each step in the degradation, where a peak of radioactivity appeared, the phenylthiohydantoin derivative of the labelled amino acid was identified by chromatography on silica gel thin-layer plates using solvent systems described previously[6,13]. Unlabelled phenylthiohydantoins were used as markers for thin-layer chromatography. The amino acid phenylthiohydantoins were scraped from the plate and counted for ^{14}C or ^{3}H activity at each successive cycle of the degradation. Release of radioactive amino acids (vertical axes) was plotted against cycle of the degradation (lower horizontal axis). At the top of the figure, in ovals, is the known amino terminal sequence of bovine proparathyroid hormone. The shaded ovals represent the hexapeptide sequence, specific to the prohormone numbered −6 to −1, with the amino terminal bovine hormone sequence beginning at position 1. The human prohormone has an identical amino-terminal sequence with the bovine species with the exception of position 1, where a serine (cross-hatched oval above the bovine sequence) represents a human specific mutation in parathyroid hormone. *a*, bovine ^{3}H-lysine and ^{14}C-arginine; *b*, human ^{3}H-lysine and ^{14}C-arginine; *c*, bovine ^{3}H-valine and ^{14}C-serine; *d*, human ^{3}H-valine and ^{14}C-serine.

sequence analysis involving all amino acids is possible with picomole quantities of polypeptide. Analyses reported here were carried out on 10 pmol of proparathyroid hormone.

Certain issues concerning the use of a carrier protein to protect trace quantities of polypeptide from chemical and mechanical losses during automated Edman degradation have been clarified[18]. The use of such carriers to achieve protected degradation is essential for the success of micromethods. In our earlier work polypeptides to be sequenced were not radioactive; rather, increased sensitivity was achieved with ^{35}S-phenylisothiocyanate. In this method, synthetic polypeptide carriers containing non-natural amino acids are necessary to avoid interference with the identification of the unknown sequence. In our new method internal labelling through biosynthesis enabled us to use as carrier a natural protein of known sequence; thereby conventional sequence analysis of the carrier protein provides a valuable monitor of the efficiency of each step of degradation of the trace, radiolabelled peptide.

Microsequencing methods involving radioactive amino acids promise to be generally applicable to the determination of the primary structure of trace quantities of other biologically important peptides. The work described here, as well as a study describing the sequence positions of a single radioactive residue (leucine) in a precursor to an immunoglobulin chain[19], suggests that the internal labelling method can be expanded to include the use of all twenty natural amino acids as radioactive precursors in the *in vitro* biosynthesis of proteins of unknown sequence. Smithies *et al.* have used such an approach for amino terminal sequence analysis of immunoglobulin chains (personal communication). Where the approach through biosynthesis is not feasible, peptides could readily be labelled with tritium to high specific activities and sequenced[20]. In some circumstances, sequence analysis of polypeptides bearing radioactive side chain prosthetic groups may be informative. These techniques that can be used to label polypeptides internally at high specific activity, coupled with the use of natural or synthetic carrier molecules, should extend the applicability of automated Edman degradation to sequence analyses of polypeptides of biological interest that are available only in trace quantities. Such advances, coupled with improvements in speed and efficiency of peptide synthesis[21], represent an amplification essential to biochemical and physiological investigation of biologically interesting polypeptides since milligram or even gram amounts of pure polypeptides can be synthesised chemically, even though they cannot be obtained from natural sources.

Effects of previous exposure on olfactory discrimination in *Acomys cahirinus*

Experiments with chicks[1–3], rats[4,5], and rhesus monkeys[6] indicate that previous exposure to a visual pattern facilitates subsequent discrimination learning involving that pattern and a novel visual stimulus. This facilitation of discrimination learning as a function of previous exposure has been found regardless of whether the exposure stimulus was the reinforced or the non-reinforced pattern in the subsequent discrimination task.

By comparison with animals exposed to only one of the visual discriminanda before testing, those exposed to both stimuli generally take considerably more trials to master a discrimination task[2,4]. Studies with monkeys and chicks indicate that animals that were familiar with both stimuli actually did less well on a discrimination task with those stimuli than did control animals for whom both of the stimuli were novel[2,7]. For both hooded and albino rats, however, subjects familiar with both visual discriminanda learned a discrimination task faster than did control animals[4,8,9].

In general, such studies have consistently been concerned with visual stimuli; even though vision is not the dominant sense in the rat which is often used as a test species. Here we report a first attempt to investigate the effects of previous exposure to one or both discriminanda upon subsequent discrimination of olfactory stimuli. The subject species, *Acomys cahirinus* (spiny mouse) is a nocturnal murid rodent little used in laboratory experimentation.

Individual adult male spiny mice were randomly assigned to one of three treatment conditions ($n = 8$ per condition) which varied as a function of whether the animals were exposed to one, both, or neither of the olfactory stimuli for 7 d before the start of testing. The two olfactory stimuli, ethyl benzoate (EB) and acetophenone (AC) have similar diffusion rates and have been effectively used in previous studies with rats[10], guinea pigs[11,12], and garter snakes[13]. The odourants were dropped onto cotton wool inside small plastic cannisters with holes drilled through the cap. Two of these cannisters were placed in the cage of each subject on the first day of exposure training and remained for 7 consecutive days. The cannisters in the cages of the control (C) animals remained empty throughout the training period; for the Experimental II (E-II) animals, one cannister contained AC and the second EB; the cannisters in the cages of the Experimental I (E-I) mice both contained the same odour (either AC or EB), which was randomly determined for each E-I subject. Mice were housed in four separate rooms as a function of the training odour(s) to which they were exposed.

Each animal was given a single 10 min habituation period in the olfactory discrimination apparatus (a T maze consisting of a runway with a short stem) on the first and second days of stimulus exposure. On days 3–7 of exposure, each mouse was given four pretraining trials during which he was placed into one end of the runway and allowed to run to the opposite end to obtain a small bit of apple. Discrimination trials began on day 8.

During discrimination testing, the two odours were blown into opposite ends of the runway, and two small food cups containing a piece of apple as a reward were placed into the runway—one at each end. The apple in the non-reinforced (incorrect) end was inaccessible behind a mesh screen. This procedure was adopted to equate for the presence of apple odour in each end of the runway. To obtain the apple reinforcement, the mouse had to approach the appropriate odour of the two being emitted into the T maze. A correction procedure was used[14] whereby incorrect trials were repeated until the correct choice was made. Subjects were run for a total of four reinforced trials on each day until reaching a criterion of 8/9 correct consecutive responses—or until reaching a maximum of 50 reinforced trials. Throughout the training and discrimination testing, the apparatus was washed, rinsed and dried after testing each animal on each day.

For both the E-II and C conditions, four animals were reinforced for running to AC and four for running to EB. For each of the E-I animals, the designation of reinforced compared with non-reinforced odour was randomly determined. Thus, five E-I mice were reinforced for running towards the previous exposure odour, while for the remaining three E-I animals, the exposure odour was the negative (non-reinforced)

TABLE 1 Performance on olfactory discrimination test as a function of previous exposure to the test odour(s).

	Treatment condition		
	Control (C) $n = 8$	Experimental I (E-I) $n = 8$	Experimental II (E-II) $n = 8$
Mean reinforced trials to criterion	25.25	12.87	34.12
s. d.	11.22	11.04	10.27
		$H = 10.65$, $P < .01$	
Mean errors to criterion	15.9	5.0	21.5
s. d.	9.67	8.19	11.52
		$H = 10.305$, $P < .01$	

stimulus. The left/right positions of positive and negative odours was randomly determined each day for each subject, with the limitation that each odour would be introduced from each end for two trials per d.

Table 1 includes a summary of the results of the olfactory discrimination tests. Differences between the three conditions on the number of trials to criterion and errors to criterion were analysed with the Kruskal-Wallis test. As indicated in Table 1, significant differences ($P < .01$) were found between the treatment conditions on both dependent measures. Following the significant overall H tests, all possible paired comparisons for both dependent variables were tested using the Mann-Whitney U test. The results of these *post mortem* comparisons indicate that for both the number of reinforced trials to criterion and errors to criterion, the E-1 condition had significantly lower scores than either the E-II or C conditions. When comparing trials to criterion for the E-I compared with C conditions, $U = 7$, $P = 0.006$ (2-tailed test) and for the E-I : E-II comparison, $U = 7$, $P = 0.006$. On the errors to criterion measure, the E-I : C comparison yielded $U = 7.5$, $P < .01$ and for the E-I : E-II comparison, $U = 5.5$, $P < .005$. No significant differences were obtained between the E-II compared with C conditions on either of the measures of discrimination learning (for trials to criterion, $U = 17$, $P = 0.13$; and for errors to criterion, $U = 22.5$, $P > 0.30$).

The behaviour of the E-I animals run to the exposure odour did not differ greatly from those for whom the exposure odour was the negative stimulus during discrimination testing; and both of these subgroups differed noticeably from the E-II and C conditions. The mean trials to criterion value was 15 for E-I animals for whom the exposure odour was the correct stimulus during testing, and 9.3 for those E-I animals for which the exposure odour was incorrect during subsequent testing. Mean errors to criterion values for these two subgroups of the E-I condition were 6.2 and 3 respectively.

These results indicate that spiny mice will learn to discriminate between a familiar and a novel odour faster than they will learn to discriminate between two unfamiliar odours. As animals in the E-I condition showed more rapid learning than did subjects of the other two conditions—regardless of whether the exposure odour was the rewarded or the unrewarded stimulus—this enhanced performance as a function of familiarity with one of the discriminanda cannot be due to previous attachment to the rewarded odour *per se*. These results tend to generally corroborate and extend those experiments in which previous exposure to one visual pattern has been found to facilitate subsequent discrimination between that pattern and a novel visual pattern[1,4–6].

The performance of the spiny mice exposed to one of the olfactory discriminanda (E-I) was superior to that of conspecifics who had been exposed to both discriminanda before discrimination testing. Those animals for whom both odours were familiar, performed roughly comparably to the controls for whom both odours were novel. As we have mentioned however, earlier studies in which visual stimuli were used revealed that rhesus monkeys and chicks who were familiar with both discriminanda were inferior to controls[7,2], while albino and hooded rats, for whom both visual discriminanda were familiar, learned a visual discrimination faster than did controls[4,8]. As pointed out by Chantrey[2], the visual stimuli used in these studies were probably more relevant to the diurnal rhesus monkeys and chicks than to nocturnal rodent species. On the other hand, olfaction (the sense under study here) seems to be the primary sense used by nocturnal rodents, including spiny mice. The relatively rapid acquisition of the olfactory discrimination test shown by the mice in the present study no doubt reflects the value of this capacity to nocturnal rodent species in coping with their environment. It may therefore be the case that as the value of any sense increases for the species in question, previous exposure to both discriminada to be subsequently discriminated may tend to have little effect, or to interfere with acquisition—rather than facilitate subsequent discrimination between these stimuli. It must be emphasised, of course, that this is at best a very tentative *post hoc* hypothesis. A series of parametric studies using stimuli within several senses and with the same subject species would be required to test this hypothesis effectively.

Bateson and Chantrey[7,2] interpret the poor performance of chicks and monkeys on a discrimination task in which both visual stimuli are familiar as being a result of the subjects classifying the stimuli together during the exposure period and subsequently having difficulty 'declassifying' them. In the present study, although the spiny mice that were exposed to both discriminanda did not differ significantly from the controls, they were inferior to those animals exposed to only one of the odours before testing (E-I). Therefore, it would seem that relative to the E-I condition, the E-II animals had trouble declassifying the two odours as a unitary stimulus complex as a function of their previous exposure; while the relatively poor performance of the control animals was a function of the total novelty of both discriminanda.

Role of C3 in *in vitro* lymphocyte cooperation

COMPLEMENT is one of the best known effector systems of immunological reactions, and has also recently been shown to participate in non-immunological inflammation[1], and blood clotting[2–4]. Complement arises early in both phylogeny[5] and ontogeny[6], and the concept[7] that it may in addition play a part in the induction of specific antibody production is of practical and theoretical interest. The complement C3-cleaving protein (CoF) of cobra venom and other C3-reactive agents have been shown in mice to inhibit the induction of thymus-dependent but not thymus-independent antibody responses *in vivo* (refs 7 and 8 and M.B.P., unpublished). Evidence was obtained which related suppression of antibody production to cleavage of C3, rather than to other possible effects of the C3-reactive agents, such as antigenic competition (refs 7 and 8 and M.B.P., unpublished). Interpretation of the data in terms of the role of C3 in the antibody response is difficult, however, especially as fluid phase C3 fragments (C3b and C3c) 'block' B lymphocyte C3 receptors and also suppress antigen-induced *in vitro* human lymphocyte transformation (refs 7 and 8 and M.B.P., and A. E. Butterworth, unpublished).

The requirement for C3 in cooperative antibody production was therefore studied *in vitro* where it is possible to exclude such effects as antigenic competition, and to differentiate between depletion of functional C3 and the generation of C3 fragments. The presence of murine C3 in the supernatant of mouse spleen cell cultures was first demonstrated and the effects on antibody responses of these cultures of isolated specific anti-mouse C3 antibodies were then examined.

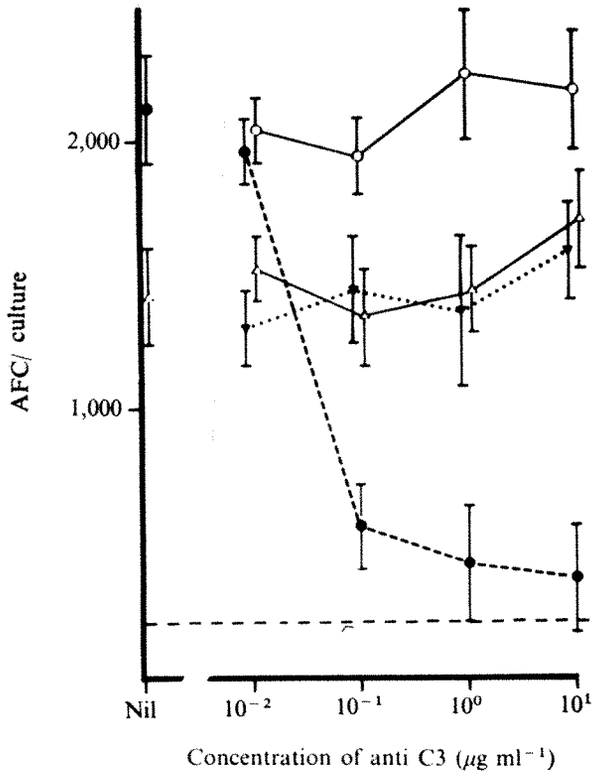

FIG. 1 Effect of anti-C3 on the response of TNP-KLH primed mouse spleen cells *in vitro*. ●, Response to TNP-KLH in the presence of anti-C3; ○, response to TNP-KLH in the presence of control IgG_1; ▼, response to DNP-POL in the presence of anti-C3; △, response to DNP-POL in the presence of control IgG_1; ----, background. Results from one seven experiments, using batch A. Values are metric means of four cultures ± s.e.m. IgM response measured at day 4.

TABLE 1 Response to DNP-POL in serum-free medium.

Cells cultured	Antigen (μg ml^{-1})	Antibody (μg ml^{-1})	Anti-DNP response (AFC per culture ± s.e.)
Normal spleen*	Nil	Nil	55 ± 28†
Normal spleen*	DNP-POL[1]	Nil	612 ± 124

* 1.5×10^7 unprimed CBA spleen cells were cultured for 4 d in serum-free medium.

† Values are arithmetic means ± s.e. mean of four cultures per group.

CBA/H mice between 60 and 196-d-old, and bred at either University College, or at the Imperial Cancer Research Fund Laboratory, London, were used throughout. Some mice were injected intraperitoneally three times at 2 week intervals with 100 μg trinitrophenylated keyhole limpet haemocyanin (TNP-KLH) or KLH absorbed on bentonite[9]. They were used for culture 4 to 12 weeks later. TNP-KLH with 800 TNP groups per 8×10^6 daltons and dinitrophenylated-polymeric flagellin (DNP-POL) with 1.7 DNP groups per 40,000 daltons, prepared as described previously[10] were used. Tissue culture was performed in Marbrook/Diener flasks[11,12] using Eagle's minimal essential medium supplemented with sodium bicarbonate and 5% foetal calf serum (Biocult Laboratories, Glasgow). In some experiments, foetal calf serum was absent. Antibody-forming cells (AFC) were counted by the technique of Cunningham and Szenberg[13]. Anti-DNP AFC were assayed by using SRC coated with a dinitrophenylated rabbit anti-SRC Fab' fragment (DNP-Fab')[14]. Only the IgM response is reported here as the IgG response were relatively low.

Isolated anti-C3 antibodies were prepared from sheep anti-mouse C3 serum by elution from Sepharose C3 (ref. 8). The anti-mouse C3 serum was raised in sheep by a modification of the method of Mardiney and Müller-Eberhard[8,15]. It was monospecific for C3, did not cross react with free or fixed bovine C3 from foetal calf serum, nor with either DNP-POL or TNP-KLH. The anti-C3 activity was estimated by agglutination of 1% sheep erythrocytes alexinated with mouse complement[8]; the protein concentrations and titres of the two preparations used in the present experiment were 90 μg ml^{-1}, 1/512 (Batch A) 170 μg ml^{-1}, 1/256 (Batch B).

Using a radioimmunoassay system (M. B. P., and D. V. Wilson, unpublished) to test for the presence of murine C3 in the supernatant of *in vitro* cultures of mouse spleen cells, it was found that the supernatants after 3.7 d culture of 1.5×10^7 spleen cells ml^{-1} regularly contained 0.3–0.6 μg ml^{-1} of murine C3, assuming that normal mouse serum used as reference standard contains 1.0–2.0 ml C3 ml^{-1}.

The effect of isolated anti-mouse C3 antibodies on the thymus-dependent response (to TNP-KLH) and the thymus-independent response (to DNP-POL) of spleen cells from mice primed to TNP-KLH was investigated. Seven experiments, the results of one of which is shown in Fig. 1, gave the same result. Anti-mouse C3 suppressed the response to an optimal dose of TNP-KLH (10^{-2} μg ml^{-1}) but did not affect that to an optimal dose of DNP-POL (10^{-1} μg ml^{-1}). The IgG_1 fractions of the same anti-mouse C3 serum depleted of anti-C3 activity did not suppress the response to either antigen; nor did anti BSA antiserum at various concentrations, which would also induce the presence of immune complexes in the cultures (results not shown). The maximum suppression obtained in different experiments varied from 100% (response of background or less) to 70% or so. Preliminary studies indicate that the least suppression occurred with spleen cells taken from mice cultured

relatively soon after priming. Analogous experiments were performed with spleen cells from mice primed with carrier only, that is, KLH (Fig. 2). Again the response to TNP-KLH 10^{-1} μg ml^{-1} was readily suppressed by anti-C3 while that to DNP-POL (1 μg ml^{-1}) was not.

The absence of suppression by anti-C3 of the response to DNP-POL was studied further, by using suboptimal concentrations of antigen. Responses to DNP-POL concentrations of 10^{-3} to 10 μg ml^{-1} were not affected by anti-C3 (10 μg ml^{-1}) (Fig. 3). It has been suggested that B cell activation *in vitro* may be dependent on bovine C3 provided by the foetal calf serum[13]. The sheep anti-mouse C3 which suppressed cooperative responses did not react with bovine C3, however, and unprimed spleen cells responded to DNP-POL in serum-free medium, even in the presence of anti-C3 (Table 1).

These results show that a thymus-dependent antibody response is suppressed by as little as 10^{-1} μg ml^{-1} of isolated anti-mouse C3 antibodies, a concentration comparable with that of murine C3 present in the culture supernates. In contrast, the thymus-independent response to DNP-POL was unaffected by as much as 10 μg ml^{-1} of anti-C3 even when suboptimal doses of antigen (Fig. 3) or serum-free cultures (Table 1) were used. Cooperative antibody production, such as induced by TNP-KLH, which requires the participation of three cell types namely T and B lymphocytes and macrophages[17,18] thus requires C3, whereas no such requirement was demonstrable in a non-cooperative response induced by DNP-POL which only involves B cells[19]. Both B cells[20] and macrophages[21] have surface receptors, albeit of different types, for fixed C3, and it is therefore possible that the role of C3 in lymphocyte cooperation may be expressed at either the B cell level, the macrophage level

or both. For example, fixed C3 interacting with cell surface C3 receptors might assist in T-dependent presentation of antigen to B cells[7,8]. The contrasting suggestion[16] that interaction of C3 with B cell C3 receptors is an obligatory signal for triggering of all B cells by either mitogens or antigens is not supported by this or other published work[7,22]. The recent observation of a difference between the B cell precursors responsive to DNP-POL and TNP-KLH, particularly in primed mice[23], might provide an alternative explanation of the present data if the difference could be correlated with heterogeneity of lymphocyte C3 receptors. A combination of cell separation and tissue culture techniques may help to clarify the role of C3 in antibody production.

Lymphocytes from human newborns abrogate mitosis of their mother's lymphocytes

THE conceptus is not automatically rejected by its mother as an allograft even though it differs genetically and therefore antigenically[1–3], perhaps in part because foetal tissues are segregated from immunologically competent maternal cells. For example, the surface of trophoblastic cells is partially covered by highly sulphated acid mucoprotein and the trophoblasts themselves have few if any transplantation antigens[3–8]. Also, blocking factors may prevent the mother from immunologically damaging her foetus(es). For example, pregnant mice have a serum factor which blocks their lymphocytes from inhibiting the growth of antigenically foreign mouse embryonic cells[9]; similar results have been observed with human materials[10,11]. We now report a further possible mechanism by which the newborn actively suppresses mitosis of maternal and other foreign lymphocytes.

Blood was obtained from the umbilical cords of male singleton newborns after delivery but before expulsion of the placenta, from their mothers' arm veins within 1 h of delivery and from nonpregnant adult females and adult males (ages 21-43, all healthy). Lymphocytes were prepared primarily from blood defibrinated by glass beads and purified by Ficoll-Hypaque gradient centrifugation[12], and on occasion passage through glass wool columns. Using Türk's reagent, lymphocyte purity was 95% or better as judged by light microscopy. Equal numbers of living lymphocytes from each mother and her newborn (1–2 × 10^6 from each) were cultured in 5 ml of RPMI 1640 media supplemented with 20% foetal calf serum, L-glutamine and antibiotics. Cultures were set up in parallel with and without phytohaemagglutinin P (PHA-P) because most cells needed PHA to go into mitosis. Adult and newborn lymphocytes cultured separately with similar amounts of PHA served as controls. We used 50 μg of PHA per ml of medium, previously determined to be an optimal dose for both types of lymphocyte. After 60–72 h incubation at 37° C in 5% CO_2 and 95% air, cultures were treated with colchicine, collected and prepared as described before[13]. Slides were stained with 0.15% quinacrine hydrochloride, washed, mounted in modified McIlwaine's citric acid buffer[14], examined by fluorescent microscopy and photographed, after which the karyotype was constructed. This technique marks the Y chromosome specifically. Under the culture conditions used, cells from mothers survived as well as cells from the newborns, as judged by trypan blue dye exclusion.

TABLE 1 Results of mixing lymphocytes from human newborns with lymphocytes from their mothers

Equal numbers of lymphocytes (1 to 2 × 10^6) from the mother and her male newborn were mixed in culture. After 3 d incubation the cells were treated with colchincine, collected and stained with quinacrine hydrochloride (to mark the Y chromosome). Usually 100 cells in metaphase were examined from each culture for the presence or absence of the Y chromosome. Lymphocytes were refined by Ficoll-Hypaque gradient centrifugation and, on occasion, by passage through glass wool columns. Under the culture conditions used, lymphocytes from the mother survived as well as lymphocytes from the newborns.

Expected result	1:1 Mixture		+ or 0	50

Equal numbers of lymphocytes (1 to 2 × 10^6) from male newborns or male adults and lymphocytes from adult females were mixed in culture. After 3 d incubation, the cells were treated with colchicine, collected and stained with quinacrine hydrochloride (to mark the Y chromosome). At least fifty cells in metaphase were examined from each culture and the percent having Y chromosome calculated. Under the culture conditions used, lymphocytes from males or females survived equally well.

Table 1 shows that after 3 d culture of a mixture of lymphocytes most cells undergoing mitosis were from the newborn. With or without PHA, 98% or more of the total cultured peripheral lymphocytes in mitosis were the newborn's (as determined by the presence of the Y chromosome), whereas 2% or less were from the mother.

In further experiments the chromosome labelling technique was used to study the mixture of lymphocytes from newborns and adult lymphocytes other than those of their mother. In all cases, lymphocytes from male newborns inhibited mitosis of lymphocytes from unrelated mothers and nonpregnant adult females (Table 2). In contrast, lymphocytes of adult males failed to inhibit mitosis of lymphocytes from adult females. Viability of cultured lymphocytes from adults and newborns was again similar in each experiment. We were unable to assess the mixing of lymphocytes from newborn females with their mothers' lymphocytes because of similarities in chromosome markers.

These results clearly show that lymphocytes from human male newborns effectively inhibit division of their mothers'

lymphocytes *in vitro*; however, lymphocytes obtained from the mother and cultured separately were able to enter mitosis. Preliminary experiments suggest that a soluble factor released from the newborn's lymphocytes may be in part responsible for inhibition of mitosis. Further, this inhibition is a general phenomenon, in that lymphocytes from newborns also block division of lymphocytes from unrelated mothers and other adult females. In contrast, lymphocytes from adult males failed to abrogate mitosis of lymphocytes from adult females, suggesting that (1) the Y chromosome per se is not important in this inhibition and (2) the inhibitory effect is a property of the lymphocytes of newborns. No attempts were made to assess the suppression of maternal response by transplantation antigens. Others have shown that lymphocytes of both the newborn and its mother respond less to mitogen stimulation when mixed together in a unidirectional mixed culture relative to paternal or other third party cells[15,16]. Experiments to be reported elsewhere show that lymphocytes from the mother are not killed when mixed only with lymphocytes from her newborn.

Our results suggest that any lymphocytes from the mother coming into contact with the foetus by transplacental passage are actively prevented from dividing. Such a process could protect foetal tissue from aggressor lymphocytes, prevent foetal rejection and explain the experimental difficulty in causing a graft *versus* host reaction in the foetus by cell transfer[1]. While lymphocytes from human male newborns can inhibit mitosis of lymphocytes from their mothers, one cannot conclude from *in vitro* data that this is the sole reason why antigenically different embryos are not injured *in vivo*.

Finally, our results offer an explanation for earlier observations that immune responses were difficult to elicit in newborn rabbits after adoptive transfer of sensitised homologous adult lymphocytes, whereas such adult lymphocytes mounted sizable antibody responses after transfer to X-irradiated homologous adult rabbits[17,18]. Perhaps lymphocytes from the newborn rabbits prevented potentially capable transferred cells from forming antibody. We are investigating whether lymphocytes from newborns can turn off a humoral response by preventing the division of primed immunocompetent cells and whether such lymphocytes are T suppressor cells.

Effects of barbiturate withdrawal on audiogenic seizure susceptibility in BALB/c mice

BARBITURATES are commonly used to prevent epileptic seizures[1], but it has also been observed that susceptibility to 'spontaneous' seizure in both normal humans and animals is increased during abrupt withdrawal from chronically administered barbiturates and other central nervous system depressants[2]. Here we show that barbiturate withdrawal is highly effective in producing audiogenic seizure susceptibility in a strain of mice which are normally resistant to seizure.

In addition, we present evidence that the barbiturate withdrawal effect is not an age-dependent phenomenon and further suggest that this drug-induced susceptibility to seizure shares features in common with the seizure susceptibility that can be induced in these same mice following a reduction of auditory input.

Audiogenic seizures, that is seizures driven by a loud sound, can be produced in normally seizure-resistant mice by 'priming' them with an intense acoustic stimulus a few days before testing for audiogenic seizures[3–5]. These primed animals show a severe loss in cochlear sensitivity indicative of cochlear damage. Saunders *et al.*[6] proposed an auditory deprivation hypothesis to account for the apparent paradox that deafened mice over-react to a loud sound. Essentially, this hypothesis suggested that priming caused damage to the cochlea which in turn effectively reduced auditory input to higher auditory structures. As a result of this disuse, the unused structures became supersensitive so that on re-exposure to a loud sound, the supersensitive structures were excited and a seizure precipitated. Gates, Chen and Bock[7] and Chen, Gates and Bock[8] later confirmed that auditory deprivation was the important condition for the development of supersensitivity.

Careful destruction of the tympanic membrane produces a reduction of input to the cochlea (approximately 40 dB) and would not seem to produce cochlear damage. There is, however, the chance that secondary infection could be introduced into the middle ear and then to the cochlea, but this did not seem to be the case with our animals. McGinn *et al.*[9] have subsequently confirmed our finding that a reduction of auditory input, by means of ear plugs, is also effective in producing audiogenic seizure-prone mice. Willott and Henry[10] report that preliminary histology from primed mice localises damage in the outer hair cells of the cochlea. Although we have no histological evidence of hair cell damage from our BALB/c mice following priming, there is no reason to believe that priming does not produce the same effect as in C57BL/6J mice. The 'poor' cochlear microphonic obtained from BALB/c mice after priming is indicative of hair cell damage.

Disuse in the nervous system, regardless of how it is produced, seems to be the condition responsible for an increase in nervous system excitability[11]. In view of the evidence

Table 1 Effects of barbiturate withdrawal on seizure susceptibility in non-susceptible BALB/c mice as a function of age

Group	Age	No.	Incidence of seizure pattern* Wild running	Clonic	Tonic	Death
Barbiturate	36 ± 3	10	10	10	9	0
Saline	36 ± 3	6	1	0	0	0
Barbiturate	270 – 275	8	8	8	5	0
Saline	270 – 275	11	1	1	1	0

* Fisher exact probability tests were used to compare the barbiturate and saline control mice for each stage of the seizure pattern. Exact probability values are given in the text.

which suggests that barbiturate anaesthetics produce a general reduction in excitability in at least some parts of the auditory pathway[12] and as a result of the suggestion put forward by Jaffe and Sharpless[13] (and others) that pharmacological disuse supersensitivity resembles other types of disuse supersensitivities, we decided to examine the effect of barbiturate withdrawal on susceptibility of BALB/c mice to audiogenic seizure.

Twenty-one mice from eight litters were divided into two groups (split litters) at 36 ± 3 d of age. This age group was the closest we could get to the immature mouse without introducing other difficulties. Each of the 14 experimental mice was given an intragastric dose of 1.8 mg (approximately 60 mg kg^{-1}) of sodium phenobarbitone dissolved in 0.3 ml of water twice daily at 12 h intervals for 5 d. The other group of seven mice was also given an intragastric dose of isotonic saline of the same volume on the same regimen. The barbiturate was given orally in both age groups. Four experimental and one control animal died during the treatment period. (We were concerned that interference with growth, through food deprivation, might introduce a confounding factor into the experiment but by lowering the dosage and increasing the time over which the drug is administered another problem is created—achieving the effect within the desired age group.)

Thirty hours after the last dose of phenobarbitone had been given to the experimental group, all mice from both groups were tested for susceptibility to audiogenic seizure by exposing each mouse to the sound of an intense electric bell (131 dB relatively to 0.0002 dyne cm^{-2}) inside a circular, sound-insulated chamber for 60 s or until seizure occurred. The types of seizure reactions were noted in those mice which convulsed and the results are shown in Table 1.

All the animals that had been withdrawn from phenobarbitone had florid seizures, but only one of the control animals showed the first stage of the audiogenic seizure sequence; that is, wild running without subsequent seizure. Fisher exact probability tests on incidence of each level of seizure behaviour reveal significant differences between the drug and saline control groups (wild running, $P = 0.0014$; clonic seizure, $P = 0.00012$; tonic seizure, $P = 0.0009$). Barbiturate withdrawal is clearly effective in inducing seizure susceptibility in these normally seizure-resistant mice.

Production of audiogenic seizure susceptibility in resistant mice by previous auditory priming is often regarded as being a developmental phenomenon; that is, the mice can only be made susceptible to seizure if priming occurs during a sensitive period when the mice are still undergoing neural maturation. Gates and Chen[14], however, have recently shown that seizure susceptibility can be achieved in adult mice if the intensity of the priming stimulus is greater than that used to prime younger animals. In view of this finding we thought it useful to examine the effects of barbiturate withdrawal on seizure susceptibility in mature mice.

Twenty-three mice from five litters were divided into two groups (split litters) of 12 and 11 respectively at 270–275 d of age. Each of the 12 experimental mice was given a 60 mg kg^{-1} intragastric dose of sodium phenobarbitone, dissolved in 0.3 ml of water, twice a day for 4.5 d and the 11 control animals were given an intragastric dose of 0.3 ml of isotonic saline on the same regimen. Thirty-four hours after the last dose of barbiturate had been administered, both groups were tested for susceptibility to audiogenic seizure using the method described previously.

The results of testing are shown in Table 1. Four of the animals in the test group died during barbiturate habituation. All of the remaining animals in this group exhibited audiogenic seizures during withdrawal and only one of the 12 control animals showed seizure behaviour. Fisher exact probability tests show that there are significant differences between the groups in incidences of wild running ($P = 0.0001$), clonic seizure ($P = 0.0001$) and tonic seizure ($P = 0.041$). Barbiturate withdrawal is therefore also an effective method for inducing seizure susceptibility in mature mice.

BALB/c mice are genetically resistant to audiogenic seizure. As we have already pointed out, however, susceptibility to seizure may be induced in these mice by exposure to either a loud sound or by depriving them of auditory input several days before the test. Fuller and Wimer[15] and Freund and Walker[16] have also shown that ethanol withdrawal is effective in inducing seizure susceptibility. Although all these methods of producing seizure susceptibility seem to be unrelated, they all share the common property of producing a depression of normal central nervous system activity. Priming produces cochlear damage which reduces input to higher auditory structures while auditory deprivation, by means of tympanic membrane destruction, has a similar effect. Phenobarbital and ethanol are both central nervous system depressants producing a reduction or depression of normal nervous activity, The major effect of reducing activity in the nervous system is that unused structures become supersensitive or over-reactive to sensory stimulation[2,17]. On exposure to a loud sound, the supersensitive structures are driven by auditory input, either directly or indirectly, and a seizure is precipitated. The audiogenic seizure is merely the behavioural manifestation of this underlying supersensitive state.

The significance of our experiment is that we have been able to induce seizure susceptibility by pharmacological means in a strain of mice which can be made susceptible to audiogenic seizure by means of auditory disuse. The fact that auditory stimulation is effective in driving a seizure during barbiturate withdrawal indicates that such a model might be useful in determining whether or not the different methods of disuse share a common or similar mechanism of supersensitivity. Our model is easily prepared and tested and lends itself to a wide variety of biochemical manipulations. These results also prompt speculation about 'spontaneous' seizures which occur in other animals during barbiturate withdrawal; such seizures may be induced by sensory stimulation.

We wish to thank Professor G. A. Bentley for his advice in execution of the experiment and in preparation of the manuscript.

Correlation between euploid structural chromosome rearrangements and mental subnormality in humans

For some time cytogeneticists have been concerned with the question of whether structural chromosome rearrangements in humans, while apparently balanced, can have deleterious effects, either physical or mental. I wish to report data which suggest that the latter at least is possible.

Between 1959 and 1972 the chromosomes of blood leukocytes of 33,533 people were examined in the Medical Research Council Clinical and Population Cytogenetics Unit in Edinburgh, and ninety-four euploid structural rearrangements of the autosomes were found, apparently of independent origin. These consisted of thirty-eight Robertsonian translocations, forty-seven reciprocal translocations and nine pericentric inversions. The chromosomes of both parents of forty-six of the subjects were studied and thirty-four of the rearrangements were found to be familial, sixteen being paternal and eighteen maternal in origin, while twelve seemed to have arisen *de novo* and are referred to here as mutants (Table 1). Blood groups and red cell and serum enzymes were studied in all the mutants and their parents and there was no evidence that the legal parents were not the biological parents.

When these data were being compiled the proportion of individuals who were mutants for a euploid chromosome rearrangement and who were also severely mentally retarded seemed to exceed chance expectation. To test this the data have been examined according to the method of ascertainment (see Tables 2 and 3 for details). At the time the original 33,533 blood samples were obtained the reason for the cytogenetic observation, that is, the method of ascertainment, was recorded for each patient. On the basis of this record the patients were divided into three groups: (*a*) those where the ascertainment was 'mental subnormality excluding Down's syndrome', (*b*) those where the ascertainment was 'consecutive or random liveborn babies', and (*c*) the remainder (Table 2). As the proportion of mutants in categories (*b*) and (*c*) was not significantly different ($P < 0.05$—Fisher's exact test) the groups were combined and the proportion of mutants in the mental subnormality group was compared with the proportion among the remainder. The proportion of mutants among the mentally subnormal was significantly greater than the proportion among the other individuals ($P < 0.01$—Fisher's exact test).

While 100% of the members of subnormal group were retarded, most being institutionalised and severely subnormal, several individuals in the other two groups must also have been mentally subnormal although only a very small proportion was likely to be severely retarded. In an attempt to see whether mutants in the other two groups were associated with mental subnormality, the method of discovery and clinical condition of the mutants in these classes were reviewed (Table 3).

Five of the seven mutants whose discovery was independent of any investigation of mental retardation were found during a survey of consecutive liveborn hospital births. One of the remaining mutants, who had a chromosome rearrangement t(3:20), (Table 3) was found during a survey of individuals occupationally exposed to ionising radiations, while the other, who had a rearrangement t(14q15q), was discovered during the investigation of a family in which a t(6p14p; 6q14q) rearrangement was segregating and it was shown that the t(14q15q) in the son must have been maternal in origin. It seems probable, especially as a break at or near the centromere of a chromosome 14 is involved in both translocations, that one rearrangement influenced the occurrence of the other[1].

All the newborn mutants appeared normal at birth, with the exception of laxity of the right hip in one baby (No. 173/71). This baby required hospitalisation at the age of 1 month because of myoclonic fits; however these were not observed in hospital and her EEG was normal. She is now well and at the age of 2 yr development seems to be normal. One child, 177/69, developed myoclonic epilepsy at the age of 3 months with a typical hypsarrhythmia pattern in his EEG. The fits were extremely difficult to control with medication and there was progressive mental deterioration until sudden death at the age of 3.5 yr. The remaining three mutant babies appear developmentally normal and the two mutant adults are physically and intellectually unremarkable.

Table 1 Euploid structural rearrangement of the autosomes

Type of rearrangement	Total No. observed	Total-where both parents examined	Mutant	Inherited Father	Inherited Mother
Robertsonian translocation	38	19	3	10	6

10	54	0	0	–
Total	2,167	12	5	2

Very few chromosome surveys of mentally subnormal individuals who do not have Down's syndrome have been published and, in almost every case where data are available, the individuals examined represent a highly selected subgroup of the mentally subnormal. The results of nine published surveys are given in Table 4 and while 12 of the 2,167 people examined were reported to have a euploid structural rearrangement, in only five were both parents examined. Two of these were found to be mutants and while these data are small, they agree with the observation that there is an excess of mutant euploid structural rearrangement among the mentally subnormal.

A deleterious effect of apparently balanced translocations in the heterozygous state has, as far as I am aware, no reported parallel in the animal kingdom. This may be because an experiment designed to detect such an effect would be virtually impossible with most laboratory animals. The phenomena may be widespread and many apparently balanced autosomal exchanges may have a deleterious effect in the heterozygous state on the cell and/or organism carrying them. The mechanism for such an effect could be either (*a*) that the rearrangement is in reality unbalanced and carries a small deletion below the level of cytological detectability; or (*b*) that chromosome breakage and exchange results in a gene mutation at one or both the break points; or (*c*) that certain rearrangements are associated with a position effect detrimental to their carriers.

Whatever the mechanism responsible, the data presented here suggest that the possession of a *de novo* euploid structural rearrangement of the autosomes is, in some cases, associated with and presumably causal to, severe mental retardation. However the follow-up of a large series of newborn babies who are mutants for a euploid structural rearrangement will be necessary before a precise prognosis for mental retardation can be made. More intensive study of mutant individuals might well enable us to determine not only the proportion of euploid mutations associated with a phenotypic effect but also the mechanism by which the effect is produced.

Negative outcome of a blind assessment of the association between spray adhesive exposure and human chromosome breakage

THE recent claim of an association of exposure to spray adhesives with a rate of chromosome breakage five to six times that in control subjects, and the report of birth defects in two children of exposed parents led the United States Federal Consumer Product Safety Commission, in August 1973, to ban abruptly the sale of these products. They were recalled from the market and a widely publicised nationwide warning urged all people exposed, particularly pregnant women, to seek chromosome studies. This resulted in widespread popular concern. Cytogeneticists throughout the country received many requests for advice from exposed women concerning termination of pregnancy and future genetic risks. Evaluation of these requests was particularly difficult because there had been no formal publication of the original data at the time of the warning. (And as of January 15, 1974 none has appeared.) The only information released to investigators who queried the Product Safety Commission directly was a copy of a letter from J. R. Seely

TABLE 1 Chromosome breakage in individuals exposed to spray adhesives and in matched controls

	Study A		Study B		Both studies together	
	Exposed	Controls	Exposed	Controls	Exposed	Controls
No. of subjects	11	11	4	4	*	*
No. of metaphases per subject	~36	~36	72	72	*	*
Total No. of metaphases studied	397	398	288	288	685	686
Frequency (and %) of cells with evidence for breakage	7 (1.8%)	3 (0.8%)	2 (0.7%)	4 (1.4%)	9 (1.3%)	7 (1.0%)
	$P = 0.34$ ($\chi_c^2 = 0.92$)		$P = 0.68$ (Fisher's exact test, two-tailed)		$P = 0.81$ ($\chi_c^2 = 0.06$)	

Phytohaemagglutinin stimulated peripheral blood was used; the total time in culture was 72 h because in all experiments collections at 48 h revealed growth too sparse to provide adequate numbers for counting. (The Oklahoma report also used cells cultured for 72 h.) Our procedure included treatment with hypotonic KCl, air drying of cell preparations dropped onto cold water-wet slides from a distance of 18 inches, and staining with carbol fuchsin. Total time in colcemid (0.5 $\mu g\ ml^{-1}$) was 2 h. Unstained areas in chromatids, no matter how large, were considered gaps not breaks, unless there was a clear discontinuity of the chromatid as well as nonalignment of the chromatid axis. Cells with gaps only were not scored as having evidence for chromosome breakage. Study *A* lasted for 2 weeks, and one batch of media was used. Exposed and control subjects could not always be set up on the same day. Only metaphases with at least forty-four centromeres were scored. In the exposed group there was one cell with a dicentric chromosome and six others, each with an acentric fragment. The dicentric and one fragment occurred in the same individual. Otherwise no more than one break occurred in any individual studied. In the controls there were two cells with isochromatid breaks and one with an acentric fragment. (There was also one dicentric in a control cell with only forty-one centromeres, and hence not scored.) In study *B*, blood from each exposed individual and matched control of a pair was drawn, cultured and studied at the same time. The specimens were coded at the time of sampling, and the code was not broken until after analysis. There was an interval of about 1 month between the sampling of first and last pairs. Individuals who were resampled from the original eleven included three of the four with heavy exposure (the fourth was unavailable) and one individual chosen randomly from the three with intermediate exposure. (The group resampled included the exposed individual in the first study with the dicentric and an acentric fragment. In none of the controls resampled had a break been found in any cell examined in study *A*.) In study *B*, two cells, each with an acentric fragment, were found in those exposed and one cell with a dicentric and three others with an acentric fragment were found in the controls.

* Seven pairs were studied once, (~36 metaphases from each subject), and four pairs twice (~108 metaphases from each subject). See text and footnote above.

at the University of Oklahoma who had made the original claim.

This evidence offered in support of the association we found suggestive, but hardly convincing, for the studies did not involve a blind assessment of chromosome breakage. The claimed relationship of birth defects to chromosome breaks and spray adhesive exposure was obscure moreover, for one of the two malformed children with alleged breaks had been conceived several months after the parents ceased use of the spray. In addition, because many of those exposed knew each other, even if there were an increased rate of chromosome breakage, this might have been caused by some other shared environmental factor.

We undertook a study of the problem in September 1973. Eleven individuals with histories of recent exposure to spray adhesives were matched with controls of the same age and sex. Blood specimens were obtained from each, coded, and set up in culture (Table 1). Approximately thirty-six metaphase plates were examined from each individual, providing a total of about 400 cells for analysis from each group. (The anticipated background rate of cells with chromosome breakage in adult controls from earlier studies was about 1.2%. Therefore, should equal rates at this level have been found in both groups, this observation would have excluded, with 95% confidence, a two-fold or greater increase over expected control rate.) When the code was broken, the results (study *A*, Table 1) revealed no significant difference between the two groups. In fact the observed frequency of breaks in the exposed subjects excluded with 95% confidence a rate five times or greater that observed in the controls, which had been the order of magnitude of the increase reported by the Oklahoma investigator. We then repeated the study on four of the original eleven subjects studied who were among those with the heaviest exposure (study *B*, Table 1). The controls were the same. Seventy-two metaphases from each individual were examined. Again there was no statistically significant difference between exposed and control subjects, and the results in the exposed excluded with 95% confidence a rate twice or more that observed in the controls.

No experiment can ever prove negative results, that is the absence of a difference between exposed and controls. The results can only put boundaries on the confidence limits of the observed rates in a particular group of people with a particular history of exposure. Our observations, however, provide no grounds to reject the null hypothesis. That is, on the basis of our results, we believe there is no reason now to accept a purported association of significant magnitude between chromosome breakage and exposure to spray adhesives.

(While our manuscript was in preparation the Consumer Product Safety Commission announced the ban would be lifted[1]. It has been reported that a blind reevaluation of the original slides failed to confirm the initial interpretation[2], and that other investigators, as well as ourselves, could not confirm the original report[2].)

This episode raises questions as to what evidence of chromosome breakage in humans should be grounds for action that may provoke unnecessary public alarm and adverse economic effects.

Linkage between immune response potential to DNA and X chromosome

INTEREST in the regulation of the immune response to nucleic acids stems largely from the spontaneous occurrence of anti-nucleic acid antibodies in the sera of patients with systemic lupus erythematosus[1–4]. Genetic factors seem to play a role in this disease, which is associated with certain human transplantation antigens[5]. Spontaneous production of antibodies to different forms of nucleic acids has been observed in some mouse strains, and is suggested to be correlated with autoimmune diseases[1–4,6–8]. It is of interest to find out whether the response potential of different mouse strains to nucleic acids, on active immunisation, is related to the spontaneous occurrence of antibodies and/or to autoimmune-like diseases.

We have previously reported that various mouse strains differ in their ability to respond to denatured DNA[9]. Thus, DBA/2 mice were found to be low responders to denatured DNA, whereas SJL/J mice were high responders to this immunogen. The SJL mice are of special interest, as they develop spontaneous reticulum cell neoplasms which resemble Hodgkin's disease in man[10], as well as some immunological abnormalities including the production of anti-nuclear antibodies[7,11]. It was found that the low responsiveness of DBA/2 mice to denatured DNA, is a result of their inability to form antibodies of the IgG class. SJL mice produced anti-denatured DNA antibodies of both 7S and 19S classes, whereas DBA/2 mice elicited only 19S antibodies[9].

Here we demonstrate that the ability to respond to denatured DNA is genetically regulated by an X-linked gene carried on the X chromosome.

SJL mice, DBA/2 mice, their (SJL × DBA/2)F1 hybrids and the backcrosses of the SJL and DBA/2 females with F1 males, namely, SJL × F1 (SJL × DBA/2) and DBA/2 × F1 (SJL × DBA/2), were injected intraperitoneally with 150 μg denatured DNA in a complex with equal weight of methylated bovine serum albumin (MBSA).

The mice were immunised twice within a 3 week interval. The first immunisation was given in complete Freund's adjuvant, whereas in the second one the denatured DNA-MBSA complex was given in phosphate-buffered saline (0.01 M sodium phospate buffer, *p*H 7.0, 0.15 M NaCl). The mice were bled 10 d after the second injection, and their sera were tested for anti-DNA titres by the antigen binding capacity assay, using ^{14}C-DNA, as previously described[9]. In addition, mice of the backcross DBA/2 × F1 (SJL × DBA/2) were assayed for their H-2 antigenic specificities. The animals were typed by the haemagglutination method[12,13], using anti-H-$2^{s/s}$ and anti-H-$2^{d/d}$ alloantisera[13,14].

The immune response to DNA of the animals described above, after the second injection, is demonstrated in Fig. 1. As was shown earlier[9], the SJL mice are high responders, whereas DBA/2 mice are low responders. The F1 hybrids are intermediate responders. The backcross animals, DBA/2 × F1 (SJL × DBA/2) and SJL × F1 (SJL × DBA/2), segregate in their response as expected from the response potential of the parental strains. Thus, the ability to respond to denatured DNA is genetically controlled.

Typing of the backcross mice DBA/2 × F1 (SJL × DBA/2) for their major histocompatibility (H-2) specificity indicated that the capacity to respond to denatured DNA is not linked to H-2, as the H-2^s antigenic specificity, donated by the SJL high responder strain, was detected in low and high responder animals. The results obtained with these backcross mice, however, demonstrate that the gene which regulates the response potential to DNA is on the X chromosome. All the males of the DBA/2 × F1 (SJL × DBA/2) backcross were low responders, whereas all the females responded well (Fig. 1). These results could be expected if the response to DNA is controlled by a dominant X-linked gene. All the males of this backcross possess the X_{low} allele donated by the DBA/2 low responder females. On the other hand, all the females carry one X_{high} allele donated by the parental males F1 (SJL × DBA/2). These F1 parental males carry the X_{high} allele, as they are offspring of a cross between SJL high responder females (X_{high} X_{high}) and DBA/2 low responder males (X_{low} Y). Mice of the backcross SJL × F1 (SJL × DBA/2) were good antibody producers (Fig. 1), as expected, as all of them carry at least one X_{high} allele. Thus, the females of this backcross are X_{high} X_{high} and the males are X_{high} Y.

Analysis of the antibody classes produced by mice of the backcross DBA/2 × F1 (SJL × DBA/2) indicated that a poor responsiveness to DNA is associated with inability to elicit antibodies of the IgG class, as was previously shown for the DBA/2 low responder parental strain[9]. Thus, the low responder males of this backcross produced only 19S antibodies, whereas in the sera of the high responder females, antibodies of both 19S and 7S were present.

The immune response to another nucleic acid, namely, double-stranded polyinosinic-polycytidylic acid, (poly(I)·poly(C)), was also found to be controlled by a gene on the X chromosome[15]. It has been suggested that poly(I)·poly(C) is a thymus-independent antigen, as neonatally thymectomised mice produced antibodies to this antigen[16]. The immune response to type III pneumococcal polysaccharide, which is a thymus-independent antigen, is also linked with the X chromosome[17]. Is the response potential to denatured DNA thymus independent, and if so, is an association between the

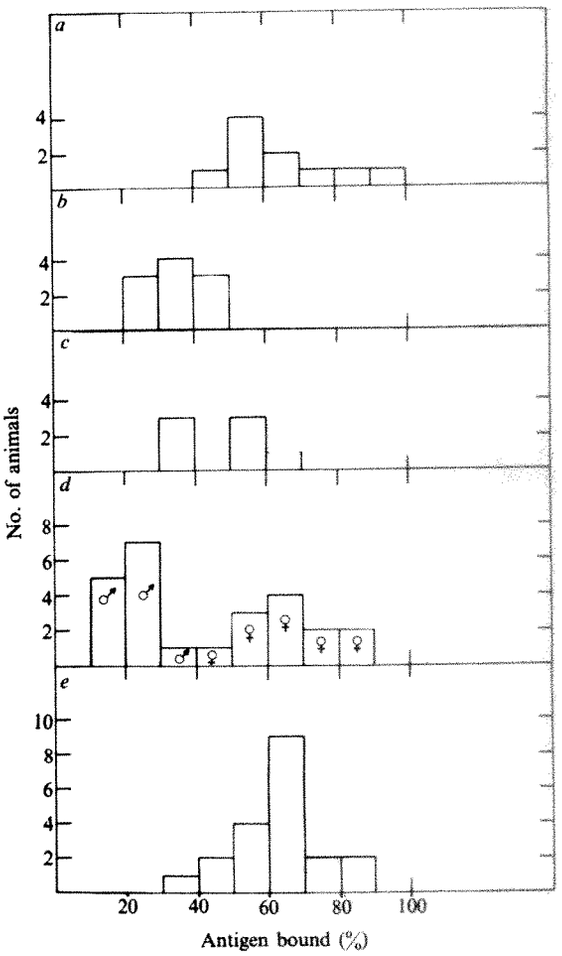

FIG. 1 The antibody response of mice immunised with denatured DNA-MBSA and assayed with ^{14}C-DNA. The horizontal axis plots the % antigen bound in the antigen-binding assay, while the vertical axis plots the number of animals falling into a given percentile for antigen bound values. 10 μl of each antiserum were assayed. *a*, SJL; *b*, DBA/2; *c*, (SJL × DBA/2) F1; *d*, DBA/2 × F1 (SJL × DBA/2); *e*, SJL × F1 (SJL × DBA/2). The sex of the animals is shown in *d*.

gene(s) controlling the response to thymus-independent immunogens and the X chromosome a general phenomenon?

An efficient immune response to denatured DNA could be obtained only when the immunogen was complexed with MBSA. Strain-dependent differences in the response potential to some synthetic polypeptides[18,19] have been shown to be obliterated when the immunogens were injected as complexes with MBSA. In the case of denatured DNA, strain differences in the ability to produce antibodies were observed following immunisation with complexes of denatured DNA–MBSA.

Here we have demonstrated a linkage between the ability of mice to respond to denatured DNA upon active immunisation, and the X chromosome. Such a linkage may contribute to the elucidation of the phenomenon of autoimmune diseases, especially if a similar association should also be found between spontaneous antibodies to DNA and the sex chromosome. This experimental approach may be of relevance for the understanding of human immune disorders, as the incidence of some autoimmune diseases in man seems to be associated with sex[20,21].

This work was supported in part by a grant from the National Institutes of Health, US Public Health Service. We wish to thank Etti Ziv and Heidy Zinger for technical assistance.

Lymphocyte separation from blood

MUCH attention has been focussed on the role of lymphocytes in the immune response of the tumour-bearing host. To study the cytotoxic effects of lymphocytes from rabbits bearing VX2 tumours towards the tumour cells *in vitro*, a suitable method for obtaining lymphocytes from peripheral blood was sought. With the recognition that both T and B lymphocyte populations are heterogeneous, and have different properties and functions which modulate each other's activities[1], the question of cell yield assumes importance in lymphocyte preparations. The method of choice should also be simple and rapid.

Several methods have been described in the literature for preparing comparatively pure lymphocyte suspensions from peripheral blood. For separation of lymphocytes from granulocytes, columns of cotton wool or glass beads have been widely used[2–4]. This method is rather lengthy and is difficult to carry out in sterile conditions. The major disadvantage is that erythrocytes are not efficiently retained by the columns, and the effluents always contain a similar or higher number of erythrocytes as lymphocytes. The yield of lymphocytes recovered by this method is usually small (about 50%). Purification of lymphocytes from blood by either Triosil (Isopaque)-Ficoll or carbonyl iron powder seemed to be simple and less time consuming, and these two methods were examined for preparing lymphocytes from rabbit blood.

Böyum[5] devised the Triosil-Ficoll method for separating lymphocytes from human blood. His lymphocyte preparation usually contained about 80% lymphocytes, 18% monocytes and 6% erythrocytes with a lymphocyte yield of greater than 95%. Harris and Ukaejiofo[6] using the same method, obtained on average 70% of the available lymphocytes. Using this Triosil-Ficoll method, we obtained lymphocyte yield from human blood of between 30% and 40% and from rabbit blood a yield of between 6% and 50%. Attempts to obtain higher yields were not successful. In addition, the purity of the lymphocyte preparations was not satisfactory.

Several groups of workers have used the carbonyl iron method for preparing lymphocyte suspensions[7–9]. These workers do not state the actual yield of lymphocytes recovered per ml of blood, although from the results of Coulson and Chalmers[7] it can be calculated that their yield for human blood was 25–50%. A lymphocyte yield from rabbit blood of greater than 70% (average 74%) has been consistently obtained by us with this technique. The yield of lymphocytes obtained from human blood, however, was always about 40%. The carbonyl iron method is simple and the entire purification procedure requires less than 2 h.

Venous blood (10 ml) was placed in a siliconised universal bottle containing 200 units of phenol-free heparin (Heparin BP (Mucous), Boots Pure Drug Co. Ltd., Nottingham, England) in 1 ml of saline. To this, 3.3 ml of sterile 1% methyl cellulose (viscosity 15 centipoise, Standard Grade, Dow Chemical Co.) in saline containing 120 mg of sterile carbonyl iron powder 3μm size (SF, GAF, Great Britain Ltd., Manchester) was added. The universal bottle containing the blood–methyl cellulose–iron mixture was incubated at 37° C for 30 min and was gently shaken at 5 min intervals. At the end of 30 min incubation, the contents of the bottle were transferred to another siliconised universal bottle which was left on a magnet at 37°C for 30 min. Red cells, granulocytes and monocytes settle with the iron particles. The supernatant, containing mainly lymphocytes and some iron particles, was pipetted off into a fresh universal bottle using a sterile Nylon Cannula (Portex Ltd., Kent, England) attached to a 1 ml syringe. The red cell pellet was spun at low speed (1000 r.p.m.) for 30 s using an MSE bench centrifuge. The supernatant was carefully pipetted off as above and added to the previous supernatant. The lymphocytes from the combined supernatants were centrifuged (2000 r.p.m. for 5 min on MSE

bench centrifuge), and washed three times with warm Waymouth medium (Medium MB 752/1, Difco Laboratories). During this washing procedure, the lymphocytes are freed from residual iron particles by resuspending the cells in the medium without disturbing the iron deposit, and decanting to a fresh siliconised universal glass bottle. Finally, the lymphocytes were suspended in Waymouth medium containing 5% bovine serum albumin previously warmed to room temperature. The differential count was performed using white blood cell (WBC) fluid (1% acetic acid in saline with two drops of methyl blue).

The lymphocyte preparation from rabbit blood contains over 95% lymphocytes compared with 50–60% lymphocytes in the blood before separation. One or two erythrocytes are usually present for every five lymphocytes, as observed by Giemsa staining. The preparation of human blood obtained by this method contains 50–60% lymphocytes compared to 30–40% lymphocytes in the original blood. Usually one or two erythrocytes are present for every lymphocyte in the suspension.

Lymphocytes prepared as above from rabbits bearing VX2 tumours are currently being investigated for cytotoxic activity towards the tumour cells previously labelled by ^{125}I-iododeoxyuridine by *in vitro* or *in vitro* methods.

T lymphocyte requirement for MSV tumour prevention or regression

Adult mice injected with murine sarcoma virus Moloney isolate (M-MSV) develop sarcomas which have a high incidence of spontaneous regression. As tumour cells are strongly antigenic and release virus continuously, it is generally agreed that tumour regression is mediated by a host immune reaction[1]. In fact, M-MSV induces a progressively growing tumour in newborn or adult mice immunologically depressed by X-irradiation, anti-lymphocyte serum or neonatal thymectomy[2–4]. It is still not clear, however, if humoral or cellular immunity is mainly responsible for M-MSV tumour regression[5–8]. Both bone marrow-derived (B) and thymus-derived (T) lymphocytes have been shown to possess a killer effect *in vitro* against target cells bearing Moloney virus specified cell surface antigens[9,10]. Here we report preliminary data which indicate that T lymphocytes are necessary for spontaneous M-MSV tumour regression.

CBA mice of both sexes were thymectomised at 2 months of age. Two weeks later they were both irradiated with 850 rad and injected intravenously with 5×10^6 syngeneic bone marrow cells. These mice were then considered 'deprived' for T cell functions. A cell-free tumour extract of M-MSV, maintained by serial *in vivo* passage in 1–2-week-old CBA or BALB/c mice, was prepared as previously reported[8]. Three to four weeks after irradiation, deprived mice were injected intramuscularly in the left thigh with 0.05 ml of this tumour extract diluted to 10^{-2} g equivalent. Control CBA mice were similarly treated. All mice were inspected daily for tumour development and growth.

As shown in Table 1, 27 of 30 deprived mice (90%) developed tumours with a mean latent period of 17 d; moreover, 24 of these 27 mice died with progressive tumours 2–3 months following M-MSV injection. No tumours were observed in M-MSV-injected control mice. These results indicate that the deficiency of the T cell population is responsible for the induction and progression of tumours in the deprived mice.

To better evaluate whether restoration of T cell function could reverse the oncogenic response, deprived mice were grafted under the kidney capsule with neonatal thymus lobes, either from CBA or CBA/H-T6T6 donors, at different time intervals before or after M-MSV injection. These mice were considered 'reconstituted' for T cell function. Reconstitution was also evaluated in mice grafted with CBA/H-T6T6 thymuses, by means of karyotypic analyses of peripheral blood lymphocytes after PHA stimulation[11]. As seen in Table 2, mice receiving the thymus graft 30 d before M-MSV injection did not develop tumours while mice which were grafted 1, 5 or 25 d after M-MSV injection presented a tumour incidence of 87.5, 69 and 100%, respectively, with a latency of 15–19 d. Furthermore, the mice reconstituted 1 or 5 d following M-MSV injection presented 100% regression while the mice grafted with a thymus 25 d after M-MSV injection presented tumours which progressed and killed the host.

It has been reported that following thymus grafting in deprived mice, a gradual restoration of T cell functions occurs and is accomplished in about 30 d (ref. 12). Consequently, our results may easily be explained in terms of complete or partial restoration of T-cell activity at the time of M-MSV injection. Thus, the mice grafted before M-MSV injection were as immunocompetent as the controls and did not develop tumours. Mice grafted 1 or 5 d after M-MSV injection present tumours but all of them regress, most likely because of a gradual increase in the T cell population during tumour growth. In this regard, the time needed for regression was greater (31 d) for mice grafted on the fifth day than that needed for mice grafted on the first day following M-MSV injection (13 d). Finally, thymus grafting 25 d after M-MSV does not affect the tumour because the neoplasm has probably reached a very advanced stage.

TABLE 3 M-MSV neutralisation titres* of sera from normal, deprived and reconstituted mice at different days following M-MSV injection

	Days from M-MSV Injection		
	15	20	60
Normal	8	16	32
Deprived	4	8	16
Reconstituted	—	16	32

Pools of sera inactivated at 56°C for 30 min, were incubated at various dilutions for 60 min at room temperature with 30–40 focus forming units (f.f.u.) of M-MSV. The mixtures of sera and M-MSV were then assayed for focus formation on DEAE-dextran treated 3T3FL mouse cells plated the day before at concentration of 10^5 in 60 mm plastic petri dishes. The cultures, in duplicate, were grown in Dulbecco's medium supplemented with 10% inactivated and filtered foetal calf serum and antibiotics. Foci were scored on the fifth day.

* Reciprocal of serum dilution that resulted in a 50% reduction of focus formation is given.

As there is evidence indicating that humoral antibodies may interfere with M-MSV tumour induction and progression[5,7,13], it was considered worthwhile to study whether deprived and reconstituted mice could produce virus-neutralising antibodies. Mice, normal, deprived and reconstituted before M-MSV, were bled at various intervals following M-MSV injection. Their sera were assayed by the *in vitro* focus reduction method on 3T3 FL cells[14]. As shown in Table 3, both deprived and reconstituted mice produced neutralising antibody, although the former had a somewhat lower titre. This last finding could be due to the decrease of antibody in free form, which is usually observed in the serum of mice with progressing tumours[6]. Alternatively, since both 19S and 7S immunoglobulins are responsible for virus neutralisation[15], it might be that the capability to synthesise 7S antibodies, which is a function of T and B cell cooperation[16], is reduced or absent in deprived mice. Obviously, the fact that deprived mice produce virus-neutralising antibody does not exclude the possibility that their serum contains also antibody with an enhancing or blocking effect, although these antibodies are mainly of the 7S type[17]. The importance of T cells in restraining M-MSV oncogenicity clearly emerges in the experimental model studied. However, whether T cells operate directly by a cytotoxic effect on tumour cells or through cooperation with B cells resulting in more efficient antibody production, remains to be elucidated.

Induced redistribution of membrane particles, anionic sites and con A receptors in *Entamoeba histolytica*

THE extent to which the distribution of antigens and other receptors at the cell surface is determined by structural components within the plasma membrane is largely unknown. In erythrocyte ghost membranes, freeze-fracture and freeze-etch studies have demonstrated that structural components, 'membrane intercalated particles', are the exclusive sites at the surface which bear A and B antigens[1,2], wheat germ agglutinin[3], influenza virus[3], con A receptors (Pinto da Silva and Nicolson, unpublished), and anionic sites[4]. It is clear, however, that conclusions derived from the study of this membrane system cannot be freely extrapolated to living cells where the relationship cell surface-membrane structure may be more complex. We report a study of this relationship on the plasma membrane of living *Entamoeba histolytica* cells in conditions which induce a redistribution of membrane intercalated particles, anionic sites or con A receptors.

Trophozoites of *E. histolytica*, a pathogenic strain cultured under axenic conditions[5], were washed with phosphate-buffered saline (PBS). Aggregation of membrane particles was induced by gradual impregnation with 25% glycerol in PBS, incubation for 30 min at 34° C and 30 min more at

CAN YOUR LIBRARY AFFORD MORE SPACE?

MICROFORM EDITIONS save space, time and money

One microfiche can carry a whole issue of a journal with up to about 90 pages. So each volume of a quarterly journal will normally be carried on four microfiches. Think of the saving in shelf space! And microform also lowers the cost of stock—which is particularly important to the new library which needs large numbers of journal back volumes and out-of-print books.

With a good system of microform indexing—in library or office—pages can be found simply and rapidly.

Gordon and Breach publish some 75 journals covering a wide range of scientific subjects, and all are available in microform. On the right are some examples of G + B journals, together with the regular subscription rates (per volume, postpaid) for printed editions for libraries.

SUBSCRIPTION RATES FOR CURRENT VOLUMES: MICROFICHE. 50% of the library subscription rate for the printed version, provided that you also subscribe to the printed version. The full subscription rate if you do not, but if you order four or more microfiche subscriptions simultaneously, any microfiche subscriptions at the full rate will be reduced by 33⅓%. This includes postage.

Gas Analysis Instrumentation

Anthony Verdin

The detection and analysis of gases and vapours has become essential in many areas of modern life; noticeably industrial safety and control of the environment. As a result a whole class of physio-chemical methods has come into existence. The author draws on his fourteen years of experience in the field to supply the only wide-ranging view of all types of equipment presently available. Both academics and industrialists will find it indispensable. £9.50

Electrical Breakdown in Gases

Edited by J. A. Rees

The electrical breakdown of gases has been studied in the laboratory since before the start of this century and it is sixty years since Sir J. S. Townsend wrote his monograph *The Theory and Ionisation of Cases by Collision*. In that time the subject has been widely studied and a great deal of progress has been made in understanding many aspects of the problem. J. A. Rees has selected the major papers in this field and has linked them with comments and an introduction. Reprinted from the the original sources, the papers together provide a unique introduction to the ionisation of gases. £7.95

Introduction to Space Charge Electron Optics

G. A. Nagy and M. Szilagyi

This introduction to space charge electron optics is an updated translation of an original Hungarian publication which presents to the West for the first time a comprehensive survey of the vast work carried out in this field in the USSR and Eastern Europe. It is however more than just a summary of literature as it also contains the solution of many problems and so points the way to future developments. £9.00

Macmillan

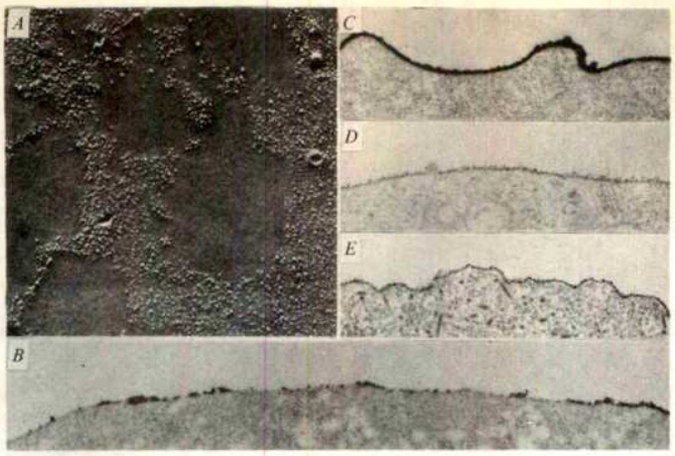

FIG. 1 Membrane intercalated particles, anionic sites and con A receptors in *E. histolytica* plasma membranes. *A*, Freeze fracture; *B*, colloidal iron at *p*H 1.8; *C*, con A–peroxidase; *D*, ferritin at *p*H 4.0; *E*, colloidal iron, prefixed cell. *A*, and *D*, 33,000; *B*, *C* and *E* × 16,500.

24° C. Cell viability of glycerol impregnated cells as determined by exclusion of trypan blue remained over 75%, dead cells being easily distinguished in thin sections or in freeze-fracture replicas. For freeze fracture, cells were rapidly frozen in the liquid phase of partially solidified Freon 22, and fractured at −100° C in a Balzers 300 apparatus equipped with a turbomolecular pump. The ultrastructural distribution of acidic sites ionised at *p*H 1.8 was determined by labelling the cells with colloidal iron[6]. Negatively charged sites ionised at *p*H 4.0 were labelled with positively charged ferritin, obtained by dialysis at *p*H 4.0, that is, below its isoelectric point[7]. Con A receptors were detected by the con A–peroxidase reaction[8].

To alter the distribution of structural components within the plane of the plasma membrane, living cells were incubated in glycerol, which results in aggregation of the membrane intercalated particles revealed by freeze fracture[9]. In our experimental conditions, we find that glycerol-induced aggregation of membrane particles in *E. histolytica* (Fig. 1*A*) is more prominent than that previously reported for lymphoid cells[9,10]. Glutaraldehyde prefixation completely prevents glycerol-induced aggregation of membrane particles. In consequence, the aggregated pattern of membrane particle distribution which is observed on the fracture faces of plasma membranes is clearly distinguished from the non-aggregated pattern observed in cells fixed before glycerol impregnation. As can be seen in other cells systems, detailed examination of uncontaminated replicas of prefixed cells demonstrates, under favourable shadowing conditions, the existence of an extremely heterogeneous particle population where all transitions ranging from a slight rugosity—here termed 'subparticle'—to a definite membrane particle can be observed. This renders difficult the unequivocal identification of membrane particles. Aggregation of membrane particles induced by glycerol, however, provides a clear distinction between smooth and particulate regions of membrane fracture faces, because both particles and subparticles coaggregate into a clearly delimited network, which leaves in between regions denuded of any rugosity. The proportion of membrane area which is occupied by aggregates of particles and subparticles varies, even within a given cell, from 30 to 70%.

Ultrastructural observation of glycerol-pretreated cells demonstrates a patchy distribution of acidic sites labelled by colloidal iron at *p*H 1.8 (Fig. 1*B*). This constrasts sharply with the continuous and uniform distribution of both con A receptors (Fig. 1*C*) and acidic sites ionised at *p*H 4.0 (Fig. 1*D*). In control cells prefixed in glutaraldehyde, uniform labelling over the entire cell surface is observed with all three reactions, as is illustrated in Fig. 1*E* for colloidal iron. Cells treated with ferritin, at *p*H 7.0, remain unlabelled.

In view of the report that con A induces aggregation of membrane particles in plasmocytoma cells[11], and the high agglutinability of pathogenic strains of *E. histolytica* relative to strains isolated from asymptomatic carriers[12], we studied the effect of con A on the distribution of membrane particles in pathogenic HK9 trophozoites. In our experimental conditions (5, 10, 20, or 100 μg ml^{-1} con A, 30 min, 34° C) the lectin does not cause any apparent alteration in the distribution of membrane particles. In addition, treatment of cells with con A does not result in redistribution of membrane receptors detected with the peroxidase–benzidine reaction. When cells are fixed after con A–peroxidase treatment, however, the electron-dense precipitate is confined to a cell region containing the uropod, in a manner analogous to 'cap' formation in lymphocytes[13], as will be reported in detail elsewhere. Freeze-fracture examination of these cells does not reveal a corresponding accumulation of membrane particles.

Our results demonstrate that glycerol treatment of *E. histolytica* cells results in marked aggregation of the membrane intercalated particles and in patchy distribution of acidic sites labelled by colloidal iron at *p*H 1.8, that glycerol induced aggregation of membrane particles is not accompanied by a redistribution of acidic sites ionised at *p*H 4.0 or of con A receptors and that con A receptors may redistribute independently of the membrane particles.

Our observations indicate that the cell surface–membrane structure relationship in *E. histolytica* cells is not straightforward. Although it remains possible that anionic sites labelled at *p*H 1.8 may correspond to the membrane intercalated particles, no such direct relationship exists between either acidic sites ionised at *p*H 4.0 or con A receptors and the membrane intercalated particles.

Platelet secretion induced by divalent cation ionophores

SECRETION by platelets is stimulated by agents of diverse structure such as thrombin, collagen and adrenaline; the substances secreted include adenine nucleotides, 5-hydroxytryptamine and calcium[1]. In many cells secretion seems to be mediated by the influx of Ca^{2+} (ref. 2), but this mechanism has not been demonstrated for all secretory systems and, in fact, no extracellular calcium is required for secretion by platelets. From kinetic studies of thrombin-stimulated secretion of ATP and calcium[3,4] we proposed that stimulus-secretion coupling in platelets is mediated by intracellular calcium. We have now tested this hypothesis with the divalent cation ionophores X-537A (Lasalocid, Hoffman-La-Roche) and A23187 (Lilly). These antibiotics increase the permeability of membranes to divalent cations and can perturb intracellular cation gradients[5–10]. The probable mechanism involves formation of lipophilic chelate compounds[10]. If secretion by platelets were mediated by the intracellular release of stored calcium (or some other divalent cation) the ionophores should disrupt the intracellular ion gradients and trigger secretion. This was the observed result.

Secretion was observed as the release of ATP, which was continuously measured by the firefly luminescence method[4]. The experiments were performed in the absence of extracellular Ca^{2+}, but addition of 1 mM Ca^{2+} or Ca^{2+} chelators did not affect the reactions. Both ionophores cause release of ATP with a time course that is nearly identical to that of thrombin-induced secretion (Fig. 1). The dependence on concentration of ionophore (Fig. 2) is consistent with other studies that show that A23187 is more effective as a calcium ionophore than is X537A (refs 5 and 7). Since the rate constant for release (Fig. 1) and the amount released (Fig. 2) are the same whether induced by thrombin or ionophores, the final steps in the multistep stimulus-secretion mechanism must be the same. In addition, no further ATP can be released by thrombin after treatment with ionophores and, conversely, ionophores do not release additional ATP from thrombin-treated platelets.

X537A and A23187 also cause release of calcium. We attempted to follow the kinetics of this release by the murexide dye binding technique[3] but this method gave spurious results in this system. The apparent yield of calcium estimated

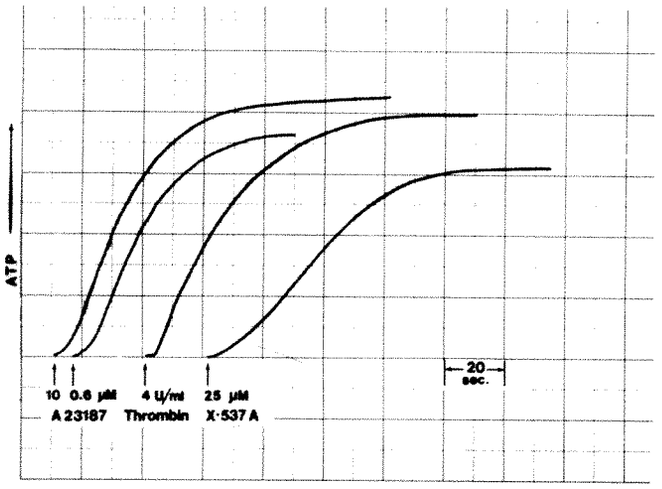

FIG. 1 Thrombin-induced and ionophore-induced secretion of ATP by washed human platelets. The preparation of platelets has been described before and ATP secretion was measured by the firefly luminescence procedure under conditions identical to those in ref. 4. A23187 was added as 5 μl of an ethanol solution and X537A as 5 μl of a dimethylformamide solution. Addition of solvents alone had no effect. Thrombin was purified by the method of Glover and Shaw[11] and had a specific activity of 1800 to 2000 U mg^{-1}.

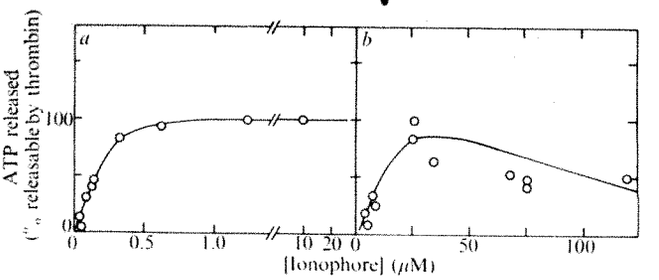

FIG. 2 Dependence of ATP secretion on concentration of ionophore. Yields are shown as percentage of ATP released by 4 U ml^{-1} of thrombin from the same platelet preparation. *a*, A23187; *b*, X537A.

from change in optical density of murexide was about twice the amount directly measured by atomic absorption. This error is probably due to binding of murexide to the membrane, a less polar environment. (We have measured large spectral shifts in murexide and calcium-murexide in non-polar solvents such as acetonitrile–water mixtures.) Atomic absorption measurements indicated that after 2 min exposure to ionophore nearly all the platelet calcium was recovered in the supernatant.

Interpretation of these results requires consideration of the known biological activity of these ionophores[5–10]. X537A causes release of accumulated Ca^{2+} from isolated sarcoplasmic reticulum vesicles and also induces contraction in intact muscle preparations[8,9]. Both compounds have also been shown to cause secretion of histamine from mast cells, but only in the presence of extracellular calcium[7]. There is no evidence that ionophores are capable of transporting ATP, and although X537A has been found to change the permeability of cells to monovalent cations or amines[3,5,7], no such effect has been shown for A23187. In this regard, we also found that the K^+ ionophore valinomycin did not cause secretion by platelets. Thus the most likely effect of the ionophores in these experiments is to disrupt divalent cation gradients. Since this must involve intracellular ion, the results are consistent with the hypothesis of an internal calcium flux triggering secretion in platelets. We favour calcium as the active ion (ionophores also transport Mg^{2+}) because of the well known role of extracellular calcium in secretion processes[2]. We therefore propose as a tentative model that there is an intracellular store of calcium analogous to sarcoplasmic reticulum in muscle. It is this calcium that triggers secretion. Thrombin causes release of the calcium by a series of steps following binding to the membrane. Ionophores by-pass the thrombin steps (just as they by-pass electrical stimulation in muscle preparations) and directly release the trigger calcium which causes secretion in the normal way.

We thank Dr Julius Berger of Hoffman-La Roche and Dr R. Hosley of Eli Lilly for X537A and A23187, and Fred Friedman for technical assistance. This work was supported by grants from the US Public Health Service.

Urinary excretion of carnitine in progressive muscular dystrophy

ABNORMAL fat metabolism in the muscles of patients with progressive muscular dystrophy is one possible explanation for the aetiology of this genetic disease but the nature of this abnormality, if any, is not known. In dystrophic mice, the skeletal muscles affected are defective in oxidising fatty acids, but can increase synthesis[1–3]. In this disease, carnitine might be expected to be involved in the impaired fatty acid metabolism, because it is of major importance in the oxidation of long-chain fatty acids as it transports them to the mitochondrial sites where they are oxidised[4–6]. If there were a carnitine deficiency, fatty acid oxidation would be impaired, resulting in an excessive synthesis of triglyceride from unoxidised substrate. To examine whether carnitine is involved in the pathogenesis of progressive muscular dystrophy, urinary excretion of carnitine was estimated in patients suffering from generalised muscular atrophy of various aetiologies.

Twenty-four hour samples of urine were collected from 54 patients; 39 with Duchenne-type dystrophy, 4 with facioscapulohumeral dystrophy, 1 with lime-girdle dystrophy and 6 with spinal progressive muscular atrophy and other diseases. As control subjects, 121 healthy men and 101 healthy women, aged from 8 to 45 yr, were studied. Carnitine was isolated from urine by Amberlite-120 (H^+) ion-exchange column chromatography and was determined by a modification of Friedman's method[7].

The results are summarised in Table 1. In normal controls, there is an obvious difference between men and women, men usually having a higher excretion rate than women. The results also indicate low carnitine excretion in all 39 boys and men with Duchenne-type dystrophy as compared with the control subjects ($P < 0.001$) and it is evident that carnitine excretion is significantly lower in all patients compared with controls, matched for sex and age. In these patients, no significant correlation was found between carnitine excretion and the severity or the duration of the disease, and the level of serum creatine phosphokinase. Carnitine excretions of the patients with facioscapulohumeral or lime-girdle dystrophy are within normal range. Six patients with spinal progressive muscular atrophy have high excretions.

TABLE 1 Urinary excretion of carnitine in healthy control subjects and in patients with neuromuscular diseases

	No. of cases	Carnitine excretion (mg d^{-1})
Normal control male	121	57.7 ± 9.6
female	101	44.1 ± 2.9
Duchenne-type dystrophy	39	30.9 ± 3.2
Facioscapulohumeral dystrophy	4	59.9 60.5 61.8 63.4
Lime-girdle dystrophy	1	44.7
Myotonic dystrophy	2	29.2 58.6
Spinal progressive muscular atrophy	6	63.4 65.5 71.5 92.6 103.0 148.8
Amyotrophic lateral sclerosis	1	71.6
General muscle cramp[8]	1	36.8

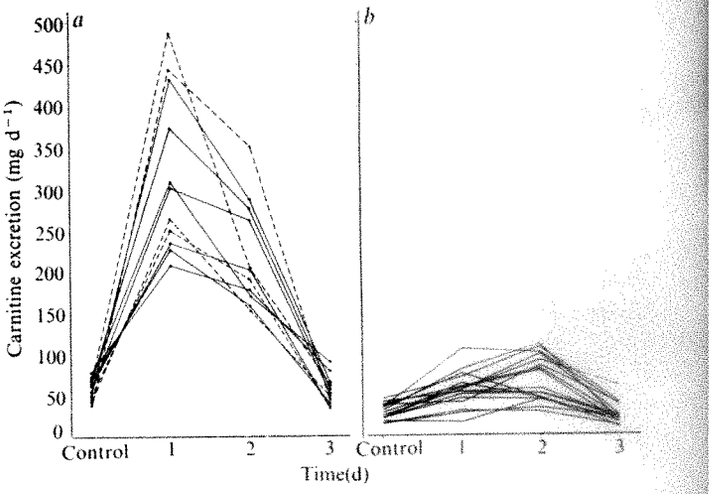

FIG. 1 Changes of urinary excretion of carnitine in patients with Duchenne-type muscular dystrophy and in control subjects before and after injection of synthetic β^{1-24}ACTH-Z. Synthetic β^{1-24}ACTH-Z 1 mg was injected intramuscularly at 0800 h on the first day of the experiment and then urine collections were made consecutively for 3 d. *a*, Normal control; ——, men; – – –, women; *b*, Duchenne-type dystrophy.

Figure 1 illustrates the effect of synthetic β^{1-24} ACTH-Z on urinary excretion of carnitine in the control subjects and in the patients with Duchenne-type dystrophy. ACTH-Z injection stimulated carnitine excretion in the controls, but not in the patients. In other diseases, spinal progressive muscular atrophy and general muscle cramp[8], ACTH-Z injection did increase urinary excretion to the same extent as that in the controls. ACTH has been known to have some lipolytic activity, but the mechanism whereby it promotes cranitine excretion remains to be elucidated.

Engel and Angelini[9] demonstrated in a myopathy with excessive lipid that the patient's muscle homogenates had an impaired ability to oxidise long-chain fatty acids because of the low levels of carnitine and that the changes favouring oxidation might occur after addition of carnitine to the homogenates.

The results reported here suggest that a similar deficiency state of carnitine exists in the muscles of Duchene-type dystrophy but direct evidence is lacking. Further investigations are required to draw any definite conclusion and such studies are now in progress in our laboratory.

We thank Dr M. Suzuki, Tokyo University of Education, for helpful discussion, and the doctors at the National Nishitaga Hospital for their cooperation in this study.

Early hominid ulna from the Omo basin, Ethiopia

A NEARLY complete right ulna (Loc 40–19) was recovered by G. Eck in 1971 in Member E of the Shungura Formation in the lower Omo basin of Southern Ethiopia. It was found in a locality within unit E5 which immediately underlies Tuff F, the K–Ar age for which is 2.04 Myr[1–4]. This locality has yielded other vertebrate fossils but no further hominid remains in spite of intensive searching. The lower limb of fossil hominids is much better represented than the upper and the remains that do exist are mostly fragmentary. This is the first early hominid forearm bone to be recovered in a state of completeness that will allow locomotor inferences, based on pelvic and lower limb material, to be correlated with good evidence from the upper limb.

The specimen (see Fig. 1) has been damaged both before and after fossilisation and the surface bone has many linear cracks, some of which are more than 1 mm wide and are filled with matrix. The shaft is broken in five places and at the distal three sites it has been possible to reassemble the fragments.

The ulna shaft is long and attenuated. It is curved, convex posteriorly, throughout its length. The sinuous curvature that is seen from below in modern human ulnae is scarcely detectable. The shaft is triangular in section; distally the angles become less well defined. The interosseus border forms an irregular, low crest, which fades out at the level of the bony markings for pronator quadratus. It is unlike the accentuated crest of modern human bones.

The rounded medial border forms the blunt apex of the triangular shaft section. It begins as a low ridge from the medial side of the subcutaneous border of the olecranon and continues distally to a point just proximal to where the interosseus crest is no longer palpable.

The posterior border begins as a crest at the apex of the subcutaneous area of the olecranon. The height of the crest diminishes distally, and it is impalpable in the distal third of the shaft. The border is convex laterally near its proximal end but straightens distally.

The anterior surface of the shaft lies between the medial and interosseus borders. It is damaged at the junction of its proximal and middle thirds; some surface bone is missing and some flakes of bone are depressed below the surface; this area probably included the site of the nutrient foramen. There are also cracks, parallel to the long axis of the shaft, probably produced by antero-posterior crushing of the shaft. The effect of these has been to accentuate the prominence of the medial border. The proximal end of the anterior surface is separated by an irregular ridge of bone from the triangular-shaped area just distal to the radial notch. This rough surfaced area is only very slightly hollowed, in contrast to the marked hollowing for the radial tuberosity in modern human bones.

The postero-medial surface is bounded by the posterior and medial borders. It is curved convexly in its long axis and the distal end follows the spiralling of the shaft.

The postero-lateral surface lies between the interosseus and posterior borders and is the least extensive of the three surfaces. Proximally it is flat from side to side and becomes more convex distally. It is marked by three oblique lines probably related to the attachments of the extensor and abductor muscles. A low ridge, accentuated by linear cracks in the bone, runs along the long axis of this surface, presumably marking the attachment of the deep extensor aponeurosis.

The distal third of the shaft is more cylindrical in section. It is distinguished by a prominent curved crest of bone which runs between the anterior and postero-medial aspects, marking the origin of the pronator quadratus.

The distal end of the specimen is expanded. It includes most of the head, but the posterior aspect of the shaft and the styloid process are missing. The head bears a convex articular surface on its antero-lateral side for articulation with the radius, and a much smaller, less distinct, distally directed articular surface. These surfaces, seen from below, are crescentic.

The proximal end of the ulna bears two processes, the coronoid and olecranon, and two articular areas, the trochlear and radial notches. Only the olecranon process has escaped significant damage.

The proximal surface of the olecranon is marked, from above downwards, by synovial reflection, the triceps bursa and the triceps insertion. A crest separates the olecranon from the rough triangular, subcutaneous area of the proximal end of the ulnar shaft. The subcutaneous area is in line with the posterior border of the shaft; viewed from the side, it does not project posteriorly as it does in some non-hominid ulnae. At the medial border of the olecranon process is a pronounced tubercle for the origin of flexor carpi ulnaris and for the insertion of the posterior fibres of the medial ligament of the elbow point. Distal to the tubercle is a strongly concave area for the origin of flexor digitorum

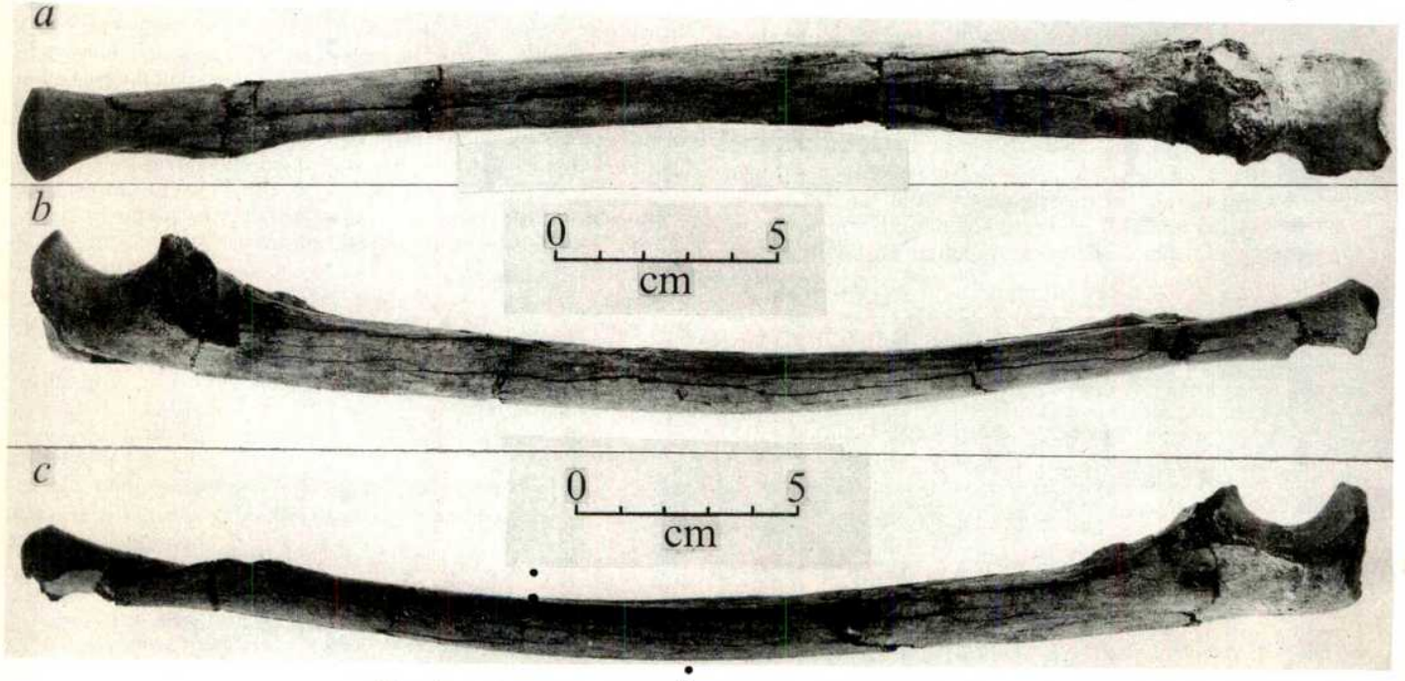

FIG. 1 *a*, Superior view of Omo ulna (Loc 40–19); *b*, lateral view; *c*, medial view.

TABLE 1 Length and curvature indices of Omo specimen and of ulnae of other higher primates

Specimens		*Homo* (=45)	*Pan* (=11)	*Gorilla* (=14)	*Pongo* (=10)	*Hyalobates* (=3)	Omo (Loc 40–19)
Maximum length	Mean	250	291	346	367	249	315
	s.d.	19.0	14.8	38.5	24.8	23.0	—
	s.e.	2.8	4.6	10.3	8.0	13.5	—
Relative length index	Mean	12.0	14.5	12.5	16.0	24.9	13.0
	s.d.	1.3	2.5	6.6	1.9	2.4	—
	s.e.	0.2	0.8	1.8	0.6	1.4	—
Curvature index	Mean	7.2	11.0	11.4	8.1	3.4	10.5
	s.d.	1.1	1.4	1.6	1.1	0.2	—
	s.e.	0.2	0.4	0.4	0.3	0.1	—

profundus. The shaft does not project proximal to the olecranon process as it does in baboon ulnae.

The coronoid process is extensively damaged along its margins. Its anterior surface, and the adjacent part of the shaft, are occupied by the ulnar tuberosity. The antero-medial side of the tuberosity is marked by a pronounced fossa for the insertion of brachialis. The lateral edge of the fossa is elevated and may be for a head of flexor pollicis longus.

The trochlear notch lies between the two processes, and is formed by two articular surfaces separated by a roughened area of bone. The proximal of the two articular surfaces is divided by a flattened central area into two nearly equal, slightly concave, areas for the flanges of the trochlea of the humerus. The distal articular surface on the coronoid process is incomplete and is divided by a ridge into a larger medial and smaller lateral surface. The lateral surface meets, at an angle, the laterally facing, concave, radial notch. Both the notch and the supinator crest, that leads distally from it, are extensively damaged.

Preliminary examination and comparisons indicate that this new fossil resembles in many respects modern human ulnae, but some features depart significantly from the modern human pattern. Morphological assessment has been supplemented by measuring some 20 parameters. The same measurements have been taken on samples of extant higher primates. These samples are small in some instances but prove adequate for this preliminary study. Features divergent from the modern human condition include:

(1) **Length of the shaft.** In the Hominoidea relative elongation of the forelimb is generally associated with suspensory postures, and this is demonstrated by the intermembral index. That this elongation is largely due to lengthening of the forearm can be demonstrated by the brachial index[5]. The maximum length of this fossil ulna and ulnae of other higher primates are given in Table 1. Using the *t* test, the probability that the fossil specimen could be included in the *Homo* sample is low ($P = <0.005$). Limb lengths are only useful when related to total body size, but from indirect evidence there is no reason to suppose that fossil hominids were taller than the modern *Homo sapiens* populations from which our sample was taken. The maximum length therefore suggests an elongated forearm for this particular fossil hominid. We have attempted to measure relative elongation of an isolated ulna by using the index

$$\frac{\text{Maximum shaft length (Martin}^{6}\text{ (1))}}{\text{Olecranon to coronoid distance (Martin (7))}}$$

The results (see Table 1) show that relative length can be related to locomotor habit—suspensory forms have high values. There is so much overlap, however, between the ranges of *Gorilla* and *Homo* that the significance of the fossil's value is difficult to assess.

(2) **Dorso-ventral curvature of the shaft.** The values for the curvature of the ulnar shaft, expressed as an index (Martin (4)), in which highly curved bones have high values, are also given in Table 1. In general, curvature is more marked in knuckle walkers than in suspensory forms. *Homo* occupies an intermediate position. The curvature seen in the African apes is presumably a response of the ulnar shaft to stresses peculiarly associated with knuckle walking, for *Papio*, with a digitigrade forelimb stance, has a straight ulna. The value of the index for this fossil specimen falls outside the human range and within that of the knuckle walkers; the probability levels are $P = <0.005$ and $P = 0.3$ respectively.

(3) **Cross-sectional profile of the ulna shaft.** Human ulnae generally have a prominent interosseus border which suggests that stresses on the interosseus membrane have dominated the final shape of the modern human ulnar shaft. A well marked bony shelf is uncommon in other hominoids and is absent in this fossil. Its absence, combined with the dorso-ventral flattening of the shaft, may indicate significantly different patterns of stress than those seen in modern human ulnae. It is possible that these differences are associated with changes in the relative bulk of forearm flexor and extensor muscles comparable with the changes which Tuttle[7] has demonstrated between knuckle walkers and humans.

(4) **Pattern of muscle origins and insertions.** The pattern of muscle markings in the fossil broadly parallels that found in modern human ulnae, though two differences may be significant. The first is the flatness and lact of buttressing of the ulnar tuberosity. The second is the weak development of the supinator crest compared with that of modern human ulnae. Further specimens may be required to determine whether these distinctions are merely the result of intra-group variability, which is substantial in man and other higher primates, or whether they reflect genuine differences in the development of the brachialis and supinator muscles in this hominid.

(5) **Shape of the ulna head.** Generally, the crescentic articular surface of the ulna head is more convex in modern human ulnae than it is in this fossil. Even if this difference is significant, its functional implications are not clear.

Overall, the functional implications of these differences from modern human ulnae point to a relatively elongated forearm and some morphological adaptations in the fossil not unlike those seen in modern knuckle walkers.

Unfortunately the ulna is still one of the least well represented parts of the skeleton among the early Hominidae. Three specimens are known for certain. Two are proximal fragments, one from Kromdraai (TM 1517) and one from East Rudolf (KNM-ER 1500); both are smaller than the Omo fossil. Their fragmentary state and the high intra-group and low between-group variability in ulnar morphology in higher primates strictly limits their usefulness.

OH, 36 ulna from Bed II Olduvai Gorge, Tanzania is complete apart from its distal end. As judged by the positions of structures that are common to both ulnae its relative length is shorter by approximately 5% than the Omo specimen and its maximum length is approximately the same as the Omo ulna. It is also more curved. The significance of any differences between the two fossils must await the detailed assessment of both specimens.

It is clear that the affinities of the Omo fossil are with the Hominidae. Mandibular and dental remains of Hominidae have been found at 11 localities within Member E of the

Shungura Formation. All, or nearly all, of this material seems to represent a robust australopithecine, but there are still no known associations of cranial and dental and postcranial parts of this hominid in most of the Omo succession. It is difficult therefore to determine the taxonomic affinities of this specimen. It seems to us that any such judgment must rely strongly on morphological features, and to a lesser extent on the functional capabilities inferred from them. These can then be related to existing hypotheses about the locomotor patterns of early hominids.

There is increasing evidence from other early hominid postcranial remains, from South and East Africa, that the morphology of robust australopithecines differed significantly from that of *Homo*[8–12]. This is now shown more clearly by material, recently announced, from East Rudolf, which is very like *Homo* and carries this dichotomy probably back beyond 2.6 million years[13]. Consequently, in view of the differences between the Omo fossil specimen and modern human ulnae, we feel that this ulna is probably that of a robust australopithecine and should be referred to *Australopithecus boisei*.

The relative elongation and the presence of certain features suggestive of a role in body support in this fossil do not necessarily mean that this creature used habitual suspensory postures or that it knuckle walked. Both these suggestions have been put forward, the first by Robinson[12], and the second by R. E. F. Leakey[14] in connection with a hominid humerus (KNM-ER 739) from East Rudolf. Tuttle, and others before him, have cogently argued that knuckle walking is a specialised means of fore-limb propulsion and support developed as a consequence of an arboreal form subsequently adapting to a terrestrial life. The morphological and functional evidence seen in this specimen is insufficient to infer such a specialised locomotor adaptation for this hominid.

Field researches of the Omo Research Expedition in southern Ethiopia have been supported by grants-in-aid (to F. C. H.) from the National Science Foundation. F.C.H. expresses his gratitude to the government of Ethiopia for the necessary authorization for this work, and in particular for the assistance and support of the Department of Antiquities which have made possible interdisciplinary studies in the lower Omo basin since 1966.

The effect of prostaglandin $F_{2\alpha}$ on ovarian blood flow and corpora lutea regression in the rabbit

In many species luteolysis is dependent upon the presence of the uterus and an intact utero-ovarian vasculature. The occurrence of prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) in uterine tissue, its specific venoconstrictor properties and its ability to induce luteolysis exogenously, led to the hypothesis that its release by the uterus might cause luteolysis by constricting the uterine and utero-ovarian veins and reducing ovarian bloood flow[1]. The observation that total ovarian venous outflow fell during infusions of $PGF_{2\alpha}$ in rats and rabbits (after laparotomy and ovarian vein cannulation) supported this hypothesis. A subsequent investigation using similar methods failed to confirm this in rats[2]. Experiments in sheep with ovaries and uterus transplanted *in toto* to the neck produced no unequivocal evidence for a drop in ovarian blood flow following doses of $PGF_{2\alpha}$ producing luteolysis, at least until oestrus ensued[3]. With increasing doses however, an immediate fall in ovarian blood flow occurred[4].

In rabbits from mid gestation to near term, the corpora lutea receives about 80% of the total ovarian arterial flow[5]. It is therefore possible that a substantial decrease in corpora luteal blood flow could be effected by regional redistribution of blood within the ovary without affecting the total flow. Novy[6] used radioactive microspheres to measure ovarian blood flow distribution in pseudopregnant rabbits and observed a 25% reduction in luteal flow on injection of $PGF_{2\alpha}$ intravenously. No significant alteration in total arterial ovarian blood flow occurred. In three sheep, which were not pregnant, corpora luteal blood flow, measured with radioactive microspheres, fell within 5.5 h from the start of a $PGF_{2\alpha}$ infusion

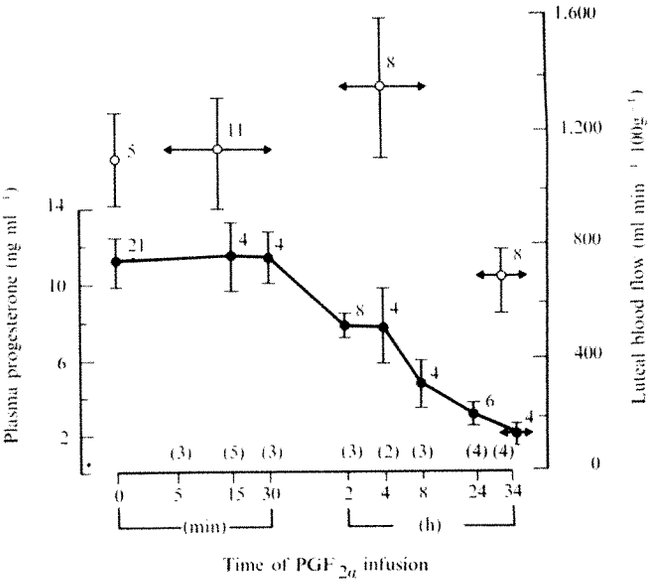

Fig. 1 Effect of $PGF_{2\alpha}$ infusion on peripheral plasma progesterone (●) and corpora luteal blood flow (○). Mean values with standard error and the number of observations are shown. The number of rabbits injected with microspheres at each time from the start of infusion is shown in brackets. Corpora luteal blood flows at time zero were determined by Abdul-Karim and Bruce[5].

TABLE 1 Ovarian blood flows (ml per min per 100 g (mean ± s.e.)) after 250 $\mu g\ h^{-1}$ $PGF_{2\alpha}$ given intra-arterially

Infusion time	*N*	Corpus luteum	Stroma	Total ovary
zero	5	1155 ± 212	127 ± 9	435 ± 59
5–30 min	11	1171 ± 196	674 ± 94*	809 ± 123
2–8 h	8	1360 ± 245	472 ± 62*	725 ± 127
24 h and delivery	8	689 ± 109	202 ± 42	327 ± 59

* significantly greater than zero time control ($P < 0.005$; *t* test)

into the uterine vein[7]. Luteolysis itself may affect the rate and distribution of ovarian blood flow. We therefore investigated the effect of $PGF_{2\alpha}$ on the chronological order of changes in ovarian blood flow and its distribution to test the hypothesis that alterations in these parameters may precede induced luteolysis.

Twenty-nine pregnant rabbits were used. The day of mating was denoted as day 0 of gestation. $PGF_{2\alpha}$ (5 ml h^{-1}) in saline solution was infused in 27 and saline alone in 2 rabbits through an aortic catheter introduced through a femoral artery, the tip being 4 cm above the origin of the ovarian arteries. The dose of $PGF_{2\alpha}$ was 250 $\mu g\ h^{-1}$ which induces labour in unanesthetised rabbits[8]. Anaesthesia was induced and maintained by an initial dose of 30 mg kg^{-1} sodium pentobarbitone and further small intravenous injections until the injection of microspheres as previously described[9]. When the infusion of prostaglandins lasted more than 8 h, sodium thiopentone anaesthesia was used for the initial placement of the infusion catheter; the rabbits were then allowed to recover and were anaesthetised with sodium pentobarbitone about 1 h before the microsphere injection. In preliminary trials, these procedures had little effect on ovarian blood flow. About 100,000 microspheres 25μm in diameter labelled with ^{46}Sc were injected into the left ventricle over 30 s, at various times after the start of the infusion (Fig. 1). Arterial plasma progesterone concentrations were measured before and during infusion with a radioimmunological method based on that of Thorneycroft and Stone[10] using petroleum ether (Mallinkrodt 30°–60°C Nanograde) instead of diethyl ether. The blood flow measurements were made on day 28 of gestation except in the two rabbits infused with saline (day 29 and 30). After the microspheres were injected, the rabbit was killed and the position of the infusion catheter was checked. The ovaries were separated into luteal and stromal components, weighed and measured for radioactivity to determine blood flows[9].

Arterial blood pressure did not alter significantly during the infusion of $PGF_{2\alpha}$, saline or during microsphere administration. There was a significant fall ($P < 0.01$; *t* test) in peripheral plasma progesterone within 2 h of the start of $PGF_{2\alpha}$ infusion (Fig. 1). This fall continued to delivery. The corpora luteal arterial blood flows were combined into three groups, those measured before the fall in plasma progesterone (5, 15 and 30 min after the start of $PGF_{2\alpha}$ infusion), those measured after a significant decline in plasma progesterone (2, 4 and 8 h) and those measured at 24 h or at delivery (Fig. 1). Blood flows in five control rabbits which were not infused[5] are also shown. There was no evidence of a decline in corpora luteal blood flow for at least 8 h after the start of $PGF_{2\alpha}$ infusion.

Even at 24 h, the mean flow was 825 ± 172 (s.e.) ml per min per 100 g ($n = 4$) or 71% of the control value. A substantial fall, to 552 ± 115 ml per min per 100 g was observed only in the four rabbits infused with $PGF_{2\alpha}$ to delivery. No difference was noted between flow rates in two rabbits receiving microspheres at delivery and one each at 0.5 and 4 h after delivery. Corpora luteal blood flow was 1,590 and 817 ml per min per 100 g in the rabbits infused with saline at 30 and 60 min following delivery, after infusions for 62 and 100 h respectively. At this time plasma progesterone was low (3.1 and 4.4 ng ml^{-1}). Table 1 shows corpora luteal, stromal and total ovarian arterial blood flows. Prostaglandin $F_{2\alpha}$ infusion had a rapid large effect on ovarian stromal flow. Five minutes after the start of infusion flow rose from a control value[5] of 127 ± 9 ($n = 5$) to 987 ± 209 (range 609–1330) ml per min per 100 g ($n = 3$). Stromal flow remained high for at least 8 h of infusion but returned to near normal at 24 h. When divided in the same way as corpora luteal blood flows, stromal flow was significantly greater between 5 min and 8 h infusion of $PGF_{2\alpha}$ but not at 24 h or delivery. Changes in total ovarian blood flows and corpora luteal blood flows were not statistically significant.

We conclude that in the rabbit luteolysis induced by $PGF_{2\alpha}$ is not preceded by a biologically significant reduction in the arterial blood flow to the corpora lutea. The mechanism of action lies elsewhere. The rise in ovarian stromal blood flow, also observed by Novy in pseudopregnant rabbits[6] is intriguing. In our experiments it was associated with a transitory decrease in placental blood flow and an increase in vaginal and cervical flow (N.W.B. and K.H., unpublished). Whether the circulatory changes in the stroma act indirectly to initiate luteolysis remains speculative, but a direct effect of $PGF_{2\alpha}$ on corpora luteal tissue must be considered.

We thank Dr G. S. Dawes for his support and encouragement and Mr H. Elvidge and staff for their assistance. N.W.B. was supported by an MRC grant and K.H. by a grant from the Agency for International Development.

Placental transfer of asbestos

ASBESTOS fibres have been reported to penetrate the walls of the stomach and intestine of animals[1,2]. Earlier work at this institution showed that asbestos fibres can pass through the walls of the digestive tract and travel throughout the body[3,4]. Additional work with neutron-activated asbestos also indicated that asbestos could cross the placenta but definite confirmation of this was not obtained[4]. Here we show, by electron microscopy, that asbestos fibres can cross the

* Young were born about 2 h after the third injection but were killed immediately.

placenta but that the extent to which this occurs is highly variable.

The same chrysotile asbestos preparation used in earlier work[3,4] containing approximately 10 × 10 fibres μg^{-1} was injected into the femoral vein of 300 g pregnant Wistar rats at levels of 1 to 3 mg (1 mg ml^{-1} water) at 2 d intervals beginning on the 10th to 14th day of gestation. The foetuses were removed by Caesarean section on the day before parturition to ensure that they did not inhale any asbestos fibres. To prevent cross contamination of the blood of the mother with the tissues of the foetuses the rats were killed by inhalation of ether and the foetuses within their intact amnionic sacs were removed from the uterus. Upon removal of the amnionic membranes the foetuses were opened and the lungs and livers saved for asbestos analysis. The livers from two foetuses (about 0.2 g) and the lungs from three (about 0.4 g) from each rat were analysed by previously described techniques[4].

In the first experiment four rats received 3 mg doses of asbestos. Two of these received 12 mg before they were sacrificed, but the other two bore young about 2 to 3 h after the third dose, apparently initiated by the stress of the injection. Preliminary experiments indicated that higher doses were usually fatal with the rats showing difficulty in breathing. This may be related to the large amount of intravenously injected asbestos which initially lodges in the lungs[4]. Extremely high values were recorded in the foetal liver and lungs from rat 7 and foetal liver from rat 8 (Table 1) but the level of asbestos fibres in the foetal tissues from rats 5 and 6 were close to the higher values in the control rats. For this reason a second experiment (Table 1, experiment 2) was conducted in which four rats again served as controls, four rats received four 1 mg injections of asbestos and four rats received five 2 mg injections.

The control values were quite low in this experiment with all but one falling below a detection level of one fibre on 10 electron microscope grid squares equivalent to 0.45 × 10^6 fibres g^{-1} in liver or about half this amount in lungs. Foetal liver and lung samples from rats receiving asbestos were again quite variable with extremely high values recorded in the livers of several rats. Such variable results are very difficult to analyse statistically but the high values are quite important in that they could result from a breakthrough of asbestos fibres in the placentas of some foetuses. A large inflow of asbestos into the blood of one foetus would probably raise the asbestos level in all its organs. This is not evident from the present data as the livers and lungs analysed were selected at random and could have come from different foetuses in the same uterus. It is possible that the extremely high values in livers of foetuses of rats 18 and 19 are the result of one or more particularly large asbestos fibres breaking through an opening between the maternal and foetal circulation in the placenta allowing many smaller fibres to follow in its wake. It is also possible that a large number of small fibres piercing the placental membrane could destroy one or more vital cells resulting in a disruption of the membrane. If this were the case and there was an intermingling of the two circulations this could suggest an additional hazard of asbestos fibres.

We conclude that the number of very high values recorded in the rats injected with asbestos compared with very low levels in the controls in the two experiments adds considerable evidence to the theory that asbestos fibres can cross the placenta. The way in which this occurs, however, by individual penetration, by a mass breakthrough or both has yet to be determined.

Magnetic field perception by electroreceptors in Black Sea skates

THE perception of the Earth's magnetic field by vertebrates for orientation purposes has been discussed for over a century[1–4]. New approaches to this, still unsolved, problem were made after the lateral line of some fish species was shown to contain electroreceptor structures[5,6]. The great sensitivity of these structures to electrical stimulation suggested that they may be an apparatus for detection of a

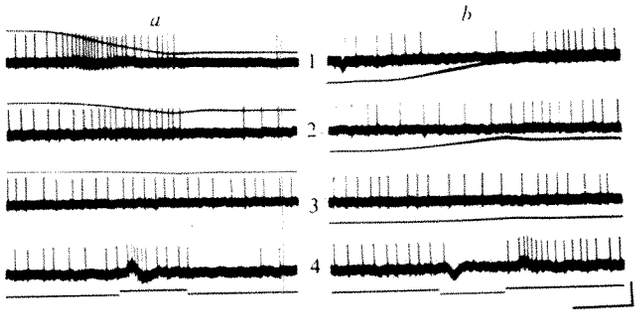

FIG. 1 Responses of the neurone in the area acoustico-lateralis of the medulla oblongata to magnetic stimuli of various intensities and opposite directions and to electrical stimuli of opposite polarities. Magnetic stimulus: 1, 80 gauss s^{-1}; 2, 36 gauss s^{-1}; 3, 9 gauss s^{-1}. *a*, South direction; *b*, north direction. 4, Responses to electrical stimulus of 3×10^{-9} A mm^{-2}. *a*, Cathodal stimulation; *b*, anodal stimulation. Time bar is 500 ms. Record of magnetic induction is 80 gs.

changing magnetic flux and thus have a role in fish orientation by means of the Earth's magnetic field[7-9]. The possibility of magnetic perception by animals having the electroreceptor apparatus, has been shown in behavioural experiments[6,10]. No direct neurophysiological data on this problem are available so far.

To investigate this problem we carried out experiments on the Black Sea skates (*Trigon pastinaca*), which have a well developed electroreceptor apparatus of ampullae of Lorenzini[10,11]. In our experiments, the single unit activity in the area acoustico-lateralis of the medulla oblongata was recorded with glass microelectrodes. Responses to electrical stimulation, as well as to the changing magnetic flux through the fish, were studied. Electrical stimuli were applied through the pair of silver electrodes placed on the skin of the fish. Magnetic stimuli were caused by a linearly increasing current of different characteristics, passed through the winding of electromagnet.

Our experiments showed that the changing magnetic field penetrating the fish evoked the response of neurones in the area acoustico-lateralis (Fig. 1), whereas the constant magnetic field failed to influence the electroreceptor system. The characteristic of the response to the changing magnetic field is dependent on the direction of the field; the intensity of the reaction is due to the rate of change of the magnetic field. The responses to magnetic stimulation could be recorded only in these neurones connected to the electroreceptor system which could easily be recognised by the responses of the neurones to electrical stimulation (current density thresholds were in the range of 10^{-9} to 10^{-10} A mm^{-2}).

The smallest change in the magnetic field evoking a neuronal response was found to be 2 gauss s^{-1}, obtained on a neurone showing no spontaneous activity. Apparently, this value could be reduced by improving the functional state of the animal.

The comparison between the magnetic flux change observed in experimental conditions and that which occurs during natural fish movements (both linear and turning) shows the possibility that the Earth's magnetic field may be perceived by electroreceptor apparatus of ampullae of Lorenzini.

Is polymorphism in two-spot ladybird an example of non-industrial melanism?

THE polymorphism exhibited by the two-spot ladybird, *Adalia bipunctata* Linn., in which specimens have a red ground colour and black spots (the typical morphs) or a black ground colour with red spots (the melanic morphs) is a well known phenomenon. The reasons for the existence of this polymorphism, however, are not well understood. Analogy to the situation in some melanic Lepidoptera, such as *Biston betularia* Linn.[1,2], is unacceptable as it would seem that selective predation by birds upon the morphs which blend less well with their surroundings would not operate upon *A. bipunctata*. Ladybirds are distasteful, have a distinctive scent, are warningly coloured and therefore are avoided by vertebrate predators[3,4].

Studies of the frequencies of the morphs of *A. bipunctata* in Great Britain have been undertaken by Creed[5-7]. He postulates that the distribution of melanics is related to industrial pollution and speculates that some, as yet unidentified, component of the polluted atmosphere is toxic to the typical morph. This explanation is not altogether satisfactory, however, for example, melanics seem to be non-existent in central and eastern London, and were present at a very low frequency before smoke control regulations were introduced[8,9]. Furthermore, there are high frequencies of melanics in rural areas of north-west England. Specimens of the melanic morph were collected as early as 1696; 150 yr before the earliest records of industrial melanism in the Lepidoptera[10]. For these reasons, together with the absence of an identified selective toxin, we re-examined the alternative hypothesis of Lusis[11] that a climatic factor, in particular solar radiation, may determine the melanic frequency.

Differences have been recorded in the temperature of small brass objects painted black or white and exposed to sunlight[12], while melanism related to seasonal temperature variations has been demonstrated in an aphid[13]. Measurements of the metabolic rates of samples of *A. bipunctata* (containing both typical and melanic morphs) showed that in the dark oxygen consumption rose from 175 μl per g live weight per h at 10° C to 296 $\mu l\ g^{-1}$ at 15° C, 721 $\mu l\ g^{-1}$ at 20° C and 985 $\mu l\ g^{-1}$ at 25° C. Thus, even a small rise in temperature causes an increase in the metabolic rate of the insect. Pairs of melanic and typical insects were enclosed in tubes and chilled in ice for 30 min. Their movements were then recorded over a period of 12 min immediately following their introduction into an arena containing a 25 mm grid. Measurements of their activity were made at two temperatures, 5° C

TABLE 1 The activity of melanic and non-melanic forms of *A. bipunctata* measured as the number of 25 mm squares entered in 12 min

Temperature (°C)	Melanic	Non-melanic
5.0	33.4 ± 7.0	8.8 ± 2.04
7.5	67.0 ± 8.17	51.0 ± 9.23

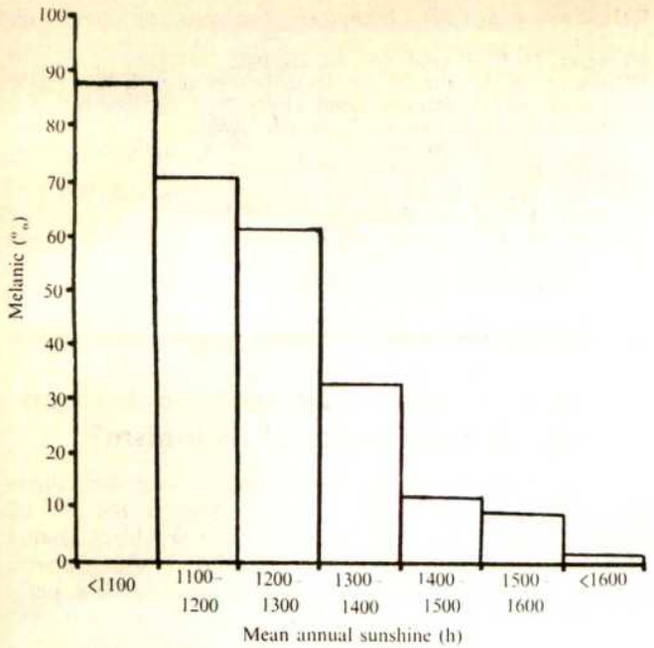

FIG. 1 Percentage of melanics in each 'sunshine class'.

and 7.5° C. Illumination was provided by a 100 W lamp suspended above the arena. The melanic insects showed greater activity at both temperatures (Table 1).

In view of the effect of illumination on activity, we believe that a lack of sunshine is the principle factor in the selection of the melanic morphs. The higher level of activity attainable by the melanic morphs will give them considerable competitive advantages in the search for food. This is especially true in areas where sunshine levels are low enough to reduce the period of activity to a point where it becomes a critical factor in the life of the insects. We have found that related species require warm, sunny conditions for mating and egg laying[14] and the same may be true for *A. bipunctata*. Thus, in localities with low sunshine levels, the mating and egg laying activity of the melanic morphs may greatly exceed that of the typical morphs. Smoke pollution may be expected to be a secondary factor in the determination of melanic frequencies as it will reduce the incident solar radiation in some areas to the critical level.

We have estimated the mean annual sunshine hours for the sites listed by Creed[5,7] from records for the years 1921-50 (ref. 15). The sites were then placed in 'sunshine classes' representing 100 h increments in the annual total. The % of melanics in each sunshine class was calculated from the numbers of the different morphs at each site. The results (Fig. 1) show a very close relationship between melanic frequency and annual sunshine hours. A correlation between melanic frequency and sunshine level at each site shows a highly significant negative correlation ($r = -0.59$, $P = <0.001$).

It seems that a re-examination of the theory of industrial melanism, as applied to *A. bipunctata*, is justified.

Changes in the plankton community of the Western English Channel

MARINE biologists and oceanographers will probably be familiar with the story of the biological and chemical changes that occurred in the Channel waters off Plymouth during the 1930s: a summary of how the plankton community altered, the numbers of young fish declined, adult demersal fish became scarcer and herring were replaced by pilchard can be found in many textbooks. The most striking feature, and one of the first to be detected, was the changeover from a plankton community characterised by the chaetognath *Sagitta elegans* and associated 'plankton indicators' to a much poorer community characterised by *Sagitta setosa*[1–3].

Since 1965, signs of a reverse change in biological conditions have been evident, and reports on the striking improvement in the numbers of young fish since then have already been published[4,5]. By 1970 the numbers of the copepod *Calanus* during the spring peak of zooplankton (May and June) were equal to those found in 1930 (ref. 6). From 1933 to 1971, however, *Sagitta setosa* remained the dominant chaetognath in the weekly samples taken off Plymouth; *S. elegans* was either completely absent or occasionally present in very small numbers[3,6–15], although in

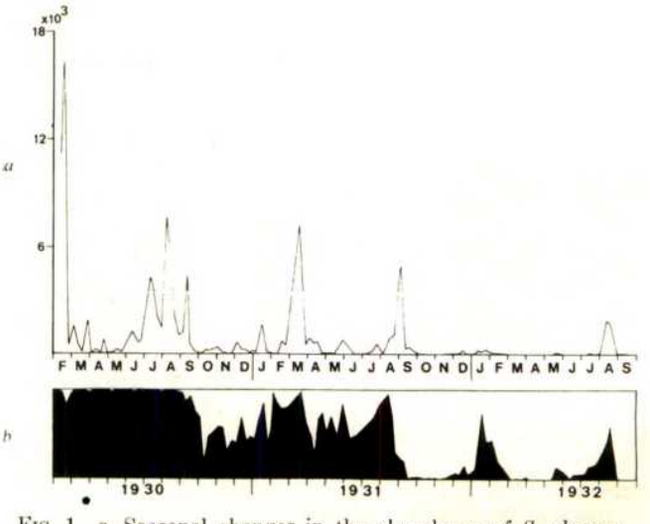

FIG. 1 *a*, Seasonal changes in the abundance of *S. elegans* (as numbers per standard haul of a 2 m net at station L5) in 1930-32, and, *b*, the proportion of *S.* elegans in the mixed population of *S. elegans* and *S. setosa* (redrawn from Russell).

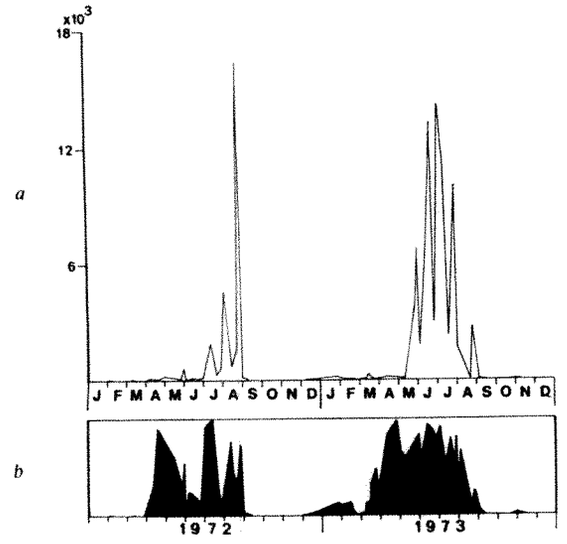

FIG. 2 *a*, Seasonal changes in the abundance of *S. elegans* (as numbers per standard haul of a 2 m net at station L5) in 1972-73; *b*, the proportion of *S. elegans* in the mixed population of *S. elegans* and *S. setosa*.

the later years after 1958 it was slightly more common in mid-channel and to the west[6,16].

It is therefore of great interest to report that in 1972, for the first time since 1932, *Sagitta elegans* was found in considerable numbers off Plymouth, even at inshore stations, and that in 1973 it was even more abundant and was the dominant species at the Eddystone station (L5) for 5 months. Over the period May to August inclusive, *S. elegans* was present in numbers equal to or greater than those recorded in the 1930s (Figs 1 and 2). The agreement between the results of weekly sampling in 1930–32 and more recent results is not complete, especially with regard to the proportions of the two species in certain of the months. The recent samples are collected with a net of very slightly narrower meshes, which retains more of the smaller sizes of chaetognaths: the total numbers of *S. elegans* (Fig. 1*a* and Fig. 2*a*) are somewhat greater, and their proportion in the combined chaetognath population (Fig. 1*b* and Fig. 2*b*) somewhat less than in the earlier period. Although the 1972 and 1973 samples did not show the spring peak of *S. elegans* found in 1930 and 1931, there were clear signs of a recurrence of this peak in 1974 and therefore the seasonal trends in abundance agree quite well.

That this return of *S. elegans* is not an isolated change is shown by the occurrence of the medusa *Aglantha* and the siphonophore *Nanomia* during the recent summers when *S. elegans* was abundant. Furthermore, in winter the euphausid crustaceans *Meganyctiphanes* and *Thyssanoessa* have been taken in night samples to the west and south-west of the Eddystone. A combination of all these north-western plankton indicators[7] with large numbers of *Sagitta elegans* has not been observed off Plymouth in any year since 1930 (ref. 17). Other indicators, such as the pteropod mollusc *Spiratella retroversa* and the larvae of the starfish *Luidia sarsi* have been abundant at certain times in the past few years, while warmer water species have become scarcer.

The recent evidence thus reinforces the view that the biological reversal reported in 1971 (ref. 6) was not a minor fluctuation but part of a much longer trend. It also seems that the order of the changes is being repeated inversely. Thus, in 1930–35 the replacement of *S. elegans* by *S. setosa* was followed by a decline in numbers of young fish and other macroplankton, and later by the appearance of large numbers of eggs of pilchard during the summer. In the more recent period a reduction in the summer pilchard eggs has been experienced since 1963, the young fish have returned in great numbers since 1966, and the numbers of the copepod *Calanus* came back to their former peak in 1970: only now, in 1973 is there a real abundance of *S. elegans*. An analysis of the corresponding hydrographic changes during the past ten years is being made by my colleague, E. I. Butler, but there seems no reason to doubt the suggested overall link with climatic fluctuation: some of the temperatures in the deeper waters below the thermocline in the past 2 yr have been the lowest recorded since the 1920s.

It could be suggested that what we have been observing off Plymouth since the 1920s is part of a cyclic fluctuation, with a peak-to-peak frequency of the order of 40 to 50 yr. *Sagitta elegans* seems to have been the first of the plankton species to show the change and the last to return, suggesting that in some way it could be more 'sensitive' to the causes of the fluctuation. Therefore a continued monitoring of this species and its associated 'indicators' may be helpful in detecting future changes in the ecosystem of the western Channel, whether naturally induced or otherwise.

Microorganisms participate in the construction of manganese nodules

THE geographical distribution and formation of manganese nodules have inspired investigation and speculation for more than a 100 years (for example, refs 1 and 2). Although photographs have revealed that some organisms attach themselves to Mn nodules on the deep seafloor (for example, ref. 3), these were apparently epiphytes, not contributing to the formation of the nodules. I now wish to suggest, on the basis of an ultrastructural examination of Mn nodules, that several groups of organisms are active in their construction.

I have found that: (*a*) numerous shelter-building organisms reside on the surface of deep-sea Mn nodules; (*b*) benthic foraminifera of the genus *Saccorhiza* attach Mn micronodules to the surfaces of macronodules as part of their tube-building activities; (*c*) some tubes of *Saccorhiza* and other benthic organisms originally constructed on nodule surfaces are buried and preserved (not replaced) within the interior of nodules; (*d*) other organisms on nodule surfaces build structures that contain large amounts of Fe and Mn compounds; (*e*) biologically derived structures cover large portions of surfaces of all the seventy-one nodules from the Pacific Ocean basin that I have examined so far.

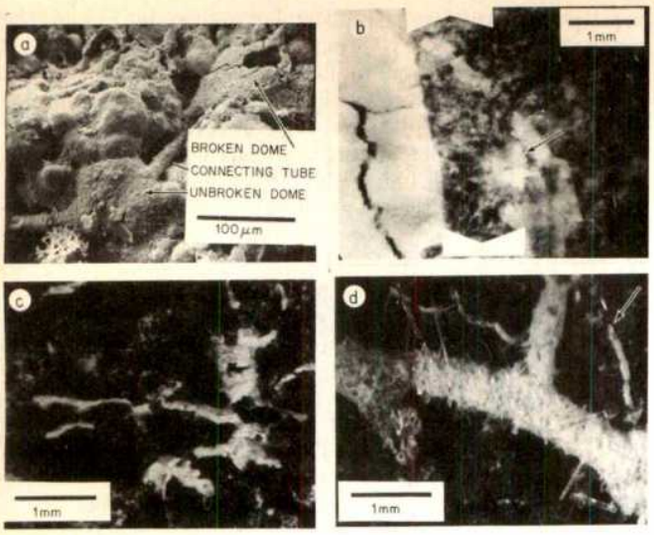

FIG. 1 Micrographs of nodule surface structures (oblique reflected light was used on all photographs except (*a*) which is from scanning electron microscopy). Small tube and dome structures (*a*) have very little contrast with the general nodule background. These structures occur in patches, or active regions, and are internally clean and empty. Structures near the borders of active regions are filled with a secondary matrix. One dome is ruptured and vacant while a second dome is intact. Massive, white, spined body is presumably a sponge (*b*) across which is a trail (marked) rich in Mn. The trail clearly proceeds from the nodule surface across the white mass and back onto the nodule surface. The arrow shows where a portion of the trail was removed to confirm that it is not the nodule surface protruding through the white mass. The organism responsible for this trail may be important in modifying the existing nodule surface by depositing or redistributing sheets of manganese oxides. Broken, partially infilled and partially covered *Saccorhiza* tubes (*c*) have some infilling material that appears to be pre-existing micro-nodules cemented in place by the tube builder while some appears to have been deposited in place as smaller tube and dome structures. This should be compared with the undamaged tube in (*d*). The smaller white tube (*d*) should be compared with Fig. 2.

Most organisms potentially important in the origin and development of nodules are microscopic (<0.5 mm across). They create fragile primary structures that are usually destroyed by any but the most careful collection process, partly explaining the lack of study of the organisms until modern sampling devices made possible recovery of undisturbed nodules.

The structures discussed here are mostly tubular or dome-shaped. The larger tubes are made of ferromanganese micronodules, mineral grains, radiolarian fragments and sponge spicules, and are identified tentatively as the remains of agglutinating *Saccorhiza*. Some of the smaller tubes and domes also seem to be agglutinated particulates. The smallest structures I have observed are hollow opaque tubes and domes, rich in Fe and Mn (Fig. 1*a*). Scanning electron microscopy suggests that these structures are precipitated *in situ*; they are dark reddish brown in reflected light, compared with dark brown or black for other spheroids on the surface of nodules. There is evidence of other microscopic life forms on nodules (Fig. 1*b*). In some regions of the nodules, particularly the bottom surfaces, thin, fragile, transparent membranes form large (1–100 mm²) canopies under which there is no sedimentary debris. (Other evidence of life forms will be detailed elsewhere.)

Some *Saccorhiza* tubes had formed on all the nodules I examined. The tubes are often broken open and the remaining fragments partially filled or covered by ferromanganese hydroxyoxides (Fig. 1*c*). Some of the infilling material seems to have formed *in situ*, and often has a distinguishable tube and dome structure (Fig. 1*a*). These observations suggest that the remains of the organisms inhabiting the nodules are incorporated into them as they grow, and that Mn micronodules are agglutinated to become part of the nodule.

If the structures produced by the organisms are preserved within the nodule, they would contribute to the overall growth of the nodule. The extreme of this hypothesis would be to consider nodules as a superstructure of surface-deposited tubes and fragments, within which would accumulate micronodules and matrix deposited organically or inorganically. To test this hypothesis, thin unsupported cross-sections of nodules were prepared. Opaque metal hydroxyoxides were leached away, leaving a fragile, nearly white framework of the original section (details to be presented elsewhere). Examination of this skeleton confirmed that preserved tubes are abundant inside nodules (Fig. 2). Preserved sections of complete tubes of *Saccorhiza* have been found, and assemblages if mineral grains of the appropriate size and arrangement are frequent. Fewks[4] and Sorem[5] have described features that are probably cross-sections of *Saccorhiza* tubes.

The preserved tubes seem to alternate with the concentric rings seen in Fig. 2, indicating that the onion-like structure of the nodules is a consequence of the particular type of remnant structure present. Alternatively, the zoning may be a result of diagenetic alteration of the nodule, perhaps under the influence of the microenvironment which is controlled by the presence of the tube material.

No leaching agent has been found that does not remove the Fe and Mn rich tubes and domes, and so direct observation of these structures has been impossible. It seems that they are either not preserved within the nodule (being altered into general matrix material) or become filled with a substance so chemically similar to themselves that leachants able to remove the filling also dissolve the structure.

The fragile remnant structure includes more than tubes and domes: there are globules of clay, thin stratiform sheets and many rather large (~0.1 mm) mineral grains. (Adjacent stratiform sheets can be confused with longitudinal cross-sections of tubular structures.)

The localisation of tubes and domes on parts of the

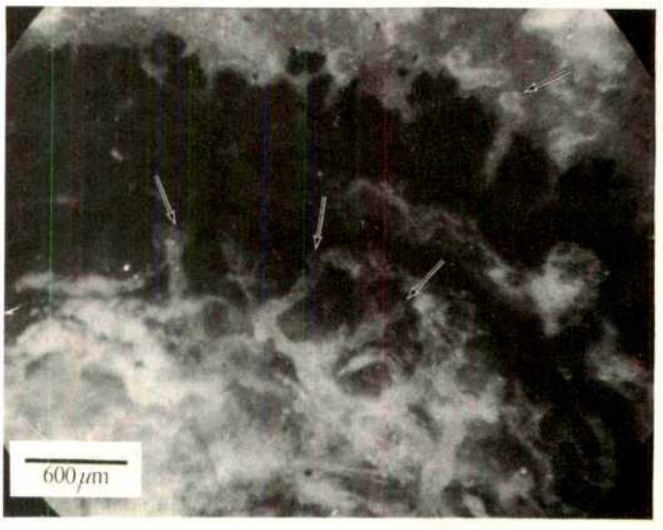

FIG. 2 Photomicrograph of tubes preserved in interior of a nodule and exposed by leaching. Leached material is nearly white, with no contrast so that dark-field photography was necessary, accounting for the poor contrast. The exposed tubes should be compared with those of Fig. 1*d* (arrow). Note the relationships of tubes and incompletely leached dark concentric rings shown in this cross-section.

nodule surfaces suggests that the organisms were 'active' at the time of collection. Most areas, however, yield no unfilled structures and are assumed to be 'dead' with respect to the relevant organisms. The greatest abundance (up to complete surface coverage) of 'active' structures occurs in regions of nodules believed to be near the sediment-water interface, suggesting that this type of growth could be responsible for the equatorial bulges in some nodules. Although all nodules investigated have had 'active' structures, 'dead' nodules with no discernible external biological produced surface structures, yet containing preserved tubes, might be expected.

It is unclear how the preserved structures were filled. Ehrlich *et al.* (ref. 6 and references therein) have adduced evidence that bacteria could play a role, but it is often suggested that slow, continuous inorganic precipitation of Mn and Fe is widespread on the ocean floor, leaving open the possibility that the infilling is entirely inorganic. The similarity of concentration ratios of several elements in adjacent sediments and nodules[7] indicates that the deposition of the metal-rich phases in both nodules and sediments is similar, whatever the process.

Graham[8] suggested that Mn nodules were of biological origin when he detected organic material in Mn crust from the Blake Plateau. He and Cooper[9] also suggested a biological origin for the 'manganese-rich' deposits of the seafloor, citing their observation of Mn coating on samples of arenaceous foraminifer skeletons from the Atlantic Ocean. The suggestions have remained unproven, principally because Graham and Cooper were unable to rule out contamination with organic matter or inorganic precipitation of Mn. Glasby and Hodgson[10] concluded from the low concentrations of organic pigments that organic influences were minimal in the formation of Mn deposits taken from the Indian Ocean. There is, however, no reason why structures such as I have found should contain significant concentrations of such pigments.

The abundance of biological structures throughout each nodule strongly suggests that the growth of deep-sea Mn nodules is aided by the activity of a diverse community of microorganisms. In an otherwise mushy environment, they build a solid superstructure within which ferromanganese oxides can accumulate.

This scheme fits well with reported observations. For example, if nodule development were dependent on biological activity, then, in the light of experience with other marine communities, nodules would be expected to be irregularly distributed geographically, which they are. They would further be expected to exhibit regularity in size, spacing and morphology within any one patch, which they do.

Radiometeric studies show that nodules are older than the sediment on which they lie, and this might be due to the activity of the microorganisms. The ability of small organisms to move large objects is well documented by Darwin's description of earthworms moving stones. The presence of microorganisms on nodule surfaces reinforces suggestions that Mn nodules could be moved by predators searching for food[2].

It is often suggested that the internal structure of nodules is the result of alternating periods of growth and decay ('alive' and 'dead'). This would explain results obtained with Be^{10} (ref. 11 and references therein), which show that nodules only grow 10% of the time. Even when 'alive', the nodules do not grow over all their surface simultaneously. Because most of the organisms involved are very small, it would require a long time to produce a new surface over the entire nodule. These observations conform with growth rates determined by several workers (1–100 mm per 10^6 yr).

Finally, if the communities of microorganisms vary from one locality to another, the nodules in the different areas might be expected to differ in shape, structure and composition. Again, such differences are common.

Of course I do not wish to imply that all constituents of Mn nodules are of biological origin. They may, in this and other respects, be analogous to coral reefs. But any model intended to explain the origin and development of deep-sea Mn nodules must take account of the extensive biological activity on their surfaces.

I thank Professor G. Arrhenius for encouragement, Professors F. Phleger and J. Gieskes for critically reading my manuscript and the Scripps Institution of Oceanography Analytical Facility for equipment. This work was done in preparation for participation in the Ferromanganese Nodule Program of the International Decade of Ocean Exploration offices of the US National Science Foundation. Support was provided by the University Research Foundation.

Photoperiodic responses in experimental hybrids of cockleburs

Hybrid intermediacy in night requirements for flowering has been reported in a study[1] of latitudinal variation of photoperiodic adaptation in cockleburs (*Xanthium strumarium* L.). The report stated that the data showed that different strains produced F1 hybrids photoperiodically intermediate between the parents and that segregation for critical night lengths was observed in the F2 generation. Ray (personal communication) feels, however, that the hybrid evaluation was possibly affected by facultative apomixis. I have also demonstrated [2,3] intermediacy of the photoperiodic response in F1 hybrids in *Xanthium* but have not found evidence of apomixis in emasculated plants.

To determine the potential role of hybridisation in their wide distribution, cockleburs from different parts of the world were crossed after they were induced to flower under experimentally controlled conditions. Plants with diverse night requirements between 7.5 h and 10.75–11 h (refs 1, 4, 5) were hybridised with day neutral plants[6,7] as well as with other photoperiodic types. The ease of producing F1 hybrids[3,8,9] within and between the members of the eight morphological complexes of Löve and Dansereau[10] extends to the production of F2 progenies; however, in crosses between the indigenous Eurasian complex, *strumarium*, and various American complexes, the F1 plants are only partially fertile[11,12].

TABLE 1 Photoperiodic adaptation of F1 hybrids involving the introduced *italicum* complex of Tahiti*

Selfed parental progenies (and morphological complex) and F1 hybrids†	Manifest night (h)‡	Apparent critical night (h)‡	Time of bud appearance outdoors in Texas §
Tahiti-A (*italicum*)	10.75–11.00	10.5–10.75	September 5–12
Tahiti-B (*italicum*)	11.00	10.75–11.00	August 25–September 8
F1 Tahiti × Pullman, Washington	9.25	9.00	June 28
Pullman (*oviforme*)	8.25	8.00	June 17–24

F1 Tahiti × Bombay, India	10.75	10.50	August 23–26
Bombay (*chinense*)	11.00	10.75–11.00	September 5–12

* Tahiti burrs were originally collected near Maraa caves. The two selfed progenies were germinated from burrs produced in growth chambers[14]. The Tahiti plants show approximately 72% acetocarmine-stained pollen similar to that of some plants (65%) along the Tamaulipas coast of Mexico. All of the F1 hybrids involving a Tahiti parent had stained pollen within the range from 54 to 68%, most exceeding 60%. For the other parents, stained pollen exceeded 99% except for San Diego plants, 65%.

† In each cross except with Eureka, California the Tahiti plant is the pistillate parent.

‡ The manifest night under varying nights in the growth chambers is the dark period under which macroscopic floral buds become visible. The apparent critical night is a preceding dark period under which floral induction probably occurred. This terminology follows that of Ray and Alexander[1].

§ The time of bud appearance is for five plants of each selfed parental or hybrid progeny under outdoor garden conditions in Austin, Texas. The plants were germinated under continuous light and transplanted to natural daylengths in mid-June approximately six weeks after sowing of the burrs. The night length, which reaches a minimum near 9 h in mid-June, should have resulted in rapid floral induction of plants with night requirements less than 9 h. The Eureka, California plants and the Eureka—Tahiti hybrids were delayed in flowering possibly because of a response to high outdoor temperatures. Other California and Australia *pennsylvanicum* plants showed a delay in the time of expected bud production.

Selfed parental progenies were compared with hybrid progenies in growth chambers under fixed and/or varying dark periods with a day temperature of 30° C and a night temperature of 24° C. Although fixed photoperiods are necessary for establishing a critical night requirement, the increasing nights enable simultaneous testing of diverse responses. In most cocklebur, the longer night accelerates bud development and, therefore, the manifest night[1] under which macroscopic floral buds appear is preceded by a shorter critical night for floral induction.

Five plants in each progeny were compared under each of two varying nights: 7.5 to 9.0 h, 8.0 to 10.0 h, 9.0 to 10.5 h, or 10.25 to 11 h. By determining the number of nights required for bud production in dark periods near the inductive one, the apparent critical night[1] was estimated. In F1 studies, the dark period was increased 15 min at 5-10 d intervals, but for testing of F2 progenies the varying nights were increased 5 min every 5 d. The various F1 progenies were germinated and kept under continuous light for 6 to 9 weeks before the varying night comparisons. The Tahiti plants were 12 weeks from sowing of the burrs when initially exposed to 10.75 h nights. Selfed progenies of day neutral parents were germinated under fixed 16 h dark periods as well as under continuous light, and subsequently flowered and produced mature achenes in both conditions. Five to ten plants of each progeny were studied outdoors from mid-June in Texas.

F1 hybrids involving a day neutral parent and/or a parent

TABLE 2 Photoperiodic adaptation in hybrid progenies of *Xanthium* under varying nights*

Selfed parental progeny (and morphological complex) and hybrid progeny†	Number of plants with macroscopic floral buds in each varying night (h min)‡							Total number of plants
	935	940	945	950	955	1000	1100

ΣF2				22	21	10	2	55

* Plants were 25 d from sowing of the burrs under continuous light when they were placed in a growth chamber nights of 9 h 20 min. The night length was increased by 5 min (±10s) each 5 d until it reached 10 h. The night length was subsequently fixed at 11 h to accelerate floral bud development. Test plants (25 d) produced macroscopic floral buds after 10 cycles of 16 h darkness. Experimental plants were 35 d from sowing at the first cycle of 9.5 h, the night expected to induce Texas *italicum* plants and Australia *cavanillesii* plants.

† F1 plants of the Australian cross were studied previously[3] and showed near midparent intermediacy.

‡ The critical night for floral induction probably preceded the manifest night by approximately 10 d, the Texas plants under nights of 9 h 30 min to 9 h 35 min and the Kentucky plants under 9 h 40 min to 9 h 45 min. In previous studies Marfa, Texas, plants[2] had indicated a critical night near 9.5 h and the Lexington, Kentucky plants[15] near 9.75 h. In other studies the Wilberforce plants[15] had shown induction under 9.5 h nights and the Manilla plants[15] under 10 h nights. My present study suggests a critical night for Wilberforce near 9 h 35 min and for Manilla near 9 h 55 min.

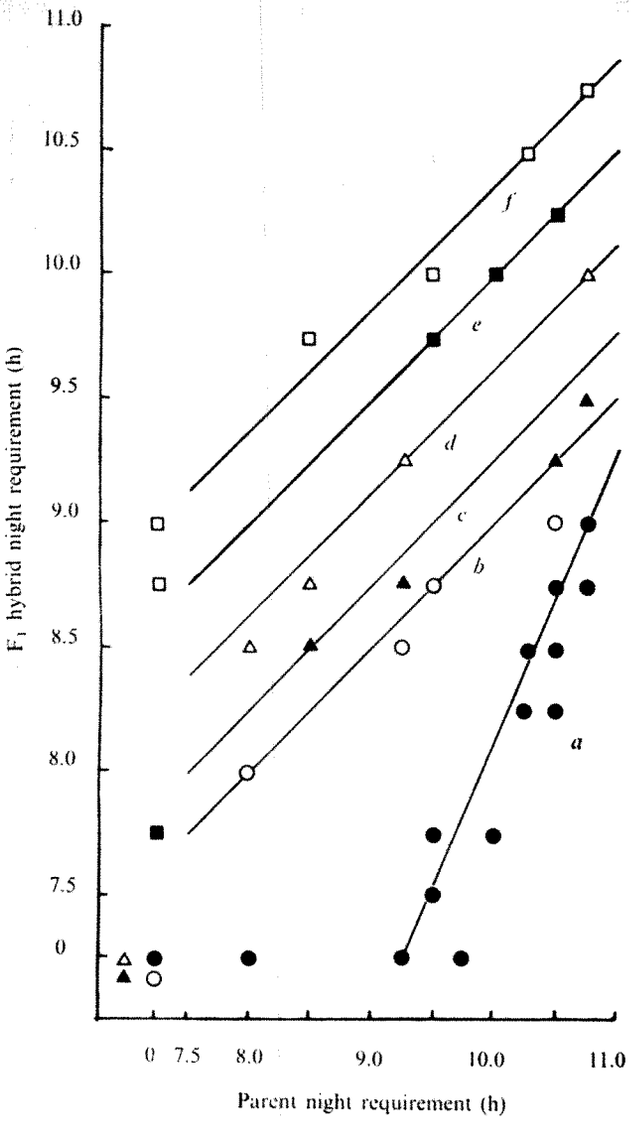

FIG. 1 Comparison of F1 hybrid night requirements for flowering. *a*, Hybrid responses with a day neutral parent (Varanasi, U. P.; Bangalore, Mysore, India) of the *strumarium* morphological complex (●). Other hybrid responses are with one of the following parents: Washington, *oviforme* (○); Italy, *italicum* (▲); Australia, *pennsylvanicum* (△); Australia, *italicum* (■); and Mexico, *italicum* or Bombay, India, *chinense* (□). The responses of hybrids between parents with night requirements are plotted along lines representing midparental intermediacy; *b*, × 8.0 h; *c*, × 8.5 h; *d*, × 9.25 h; *e*, × 10.0 h; *f*, × 10.75 h. Other parental plants used in the experimental crosses include: Eureka, California, *pennsylvanicum*, 8.0 h; Australia, *cavanillesii*, 9.5 h; Kentucky, *chinense*, 9.75 h; San Diego, California, *italicum*, 9.5–9.75 h; Brazil, *cavanillesii*, 10.25 h; Australia, *chinese*, 10.5 h; India, *chinense*, 10.25–10.5 h. Points on the graph represent the shorter night if two are indicated for a parental response.

with a critical night of 10.75–11 h show a wide range of photoperiodic adaptation (Fig. 1). The hybrids with a day neutral parent have an adaptive range from day neutrality to a 8.75–9 h night requirement[13]. Those involving a parent with a night requirement of 10.75–11 h show adaptation to nights of 8.75–9 h or longer. The crosses between day neutral plants of India and plants of Mexico[14] with the 10.75–11 h requirement produced the hybrid response to 8.75–9 h.

Approximate midparent intermediacy of the F1 hybrid response was demonstrated by most crosses involving two parents with a night requirement. Hybridisations included in Fig. 1 are those involving the *oviforme* complex from Washington, 8.0 h; the *italicum* complex from northern Italy, 8.5 h; the *pennsylvanicum* complex from Australia, 9.25–9.5 h; the *italicum* complex from Australia, 10.0 h; and either a Mexican plant in the *italicum* complex or an Indian plant in the introduced *chinense* complex, 10.75–11 h. Midparent intermediacy was also demonstrated by a series of crosses[8] involving plants from America and introductions to Australia with adaptation to various night lengths from 9.25 to 10.5 h.

F1 hybrids involving a Tahiti parent showed responses not reflecting midparent intermediacy (Table 1). Hybrid night requirements were slightly shorter than those of either parent in crosses with Bangalore and Bombay plants. The response of hybrids with San Diego and Wellington parents were similar. The hybrids with parents requiring 8 h nights showed near midparent intermediacy but were closer to the parent with the shorter night requirement. The hybrid responses may indicate a temperature interaction, differences in ripeness-to-flower (maturity) responses and/or partial dominance by one parent. Hybrids involving Hong Kong *strumarium* plants with a 9.25–9.5 h night requirement also failed to show midparent intermediacy[12,13]. With an American parent requiring a shorter night, the hybrid response was to a similarly short night. Hybrids involving an American parent with a longer requirement, 10.25–10.5 h, were intermediate in response but more similar to that parent.

F2 progenies examined under varying nights showed segregation of the photoperiodic response (Table 2). In the cross involving *italicum* from Marfa in western Texas[2] and *chinense* from Lexington, Kentucky[15] the parental requirements were separated by less than 15 min and the F2 generation, consisting of 92 plants, responded to nights differing by approximately 30 min. The cross between *italicum* and *cavanillesii* introductions[3,15] to Australia included an F2 progeny of 55 plants and a range of response to nights differing by approximately 20 min. Burr morphology and sesquiterpene lactone chemistry also show segregation in the F2 generation but the studies suggest no genetic linkage of either characteristic with photoperiodic response (my unpublished results). The F3 generation and other F2 progenies are being investigated for additional information about photoperiodic adaptation.

The F2 progenies of day neutral plants in the *strumarium* complex and *chinense* plants introduced to India[7,13] and to Australia[15,16] consisted of few plants because of partial fertility of the F1 hybrids[11,12]. Tested under natural day-lengths (and dark periods lengthening from 9 h in mid-June) in an outdoor garden following 6 weeks under continuous light in growth chambers, none of the F2 plants showed day neutrality. Each of the 13 plants that germinated from a total of 100 burrs produced on five F1 plants, showed a flowering reaction suggesting adaptation to nights shorter than 9.75 h. The selfed progeny of the day neutral parent flowered in growth chambers under continuous light; the selfed progeny of the *chinense* parents with a 10.5 h night requirement produced macroscopic floral buds in late August; the F1 and eight of the F2 plants in early July and the remaining five F2 plants before the end of July. The F1 had shown a requirement of nights of 8.25–8.75 h previously[13].

The intermediate photoperiodic response in F1 hybrids and the segregation for critical night length in the F2 generation suggest quantitative inheritance of the dark requirement for flowering. The hybridisation results also suggest that day neutrality in *Xanthium* is not dominant over a photoperiodic response as was indicated by the original studies of inheritance of photoperiodism in *Nicotiana*[17]. Day neutrality in *Xanthium* seems to result from greater negative physiological effects. Conversely, an imbalance towards increasing positive effects seems to produce the broad range of increasing night length requirements.

The diversity of photoperiodic adaptation in wild populations of *Xanthium* and the range of hybrid response may allow a broad base for future study of photoperiodic mecha-

nisms. Current physiological studies in *Xanthium* have concentrated almost exclusively on one or more strains from the vicinity of Chicago, Illinois[18] with a critical dark period usually given as 8.3–8.5 h. The actual mechanisms of photoperiodic control has been elusive but many physiological aspects of the dark induction have been reported for the Chicago strain(s)[19]. The present hybridisation studies were not intended to investigate the photoperiodic mechanism, but the results suggest that the photoperiodic response in *Xanthium* may be the total of 'negative' and 'positive' enzymatic effects and may also involve a timed reaction.

It seems unlikely that photoperiodic adaptation in *Xanthium* extends beyond the range of 7.5 to 11 h. Day neutrality is thinly separated from photoperiod controls at the short end of the range in indigenous European plants (my unpublished results) and tropical plants with a requirement near 11 h seem to have secondary controls involving temperature and maturity effects[14]. The results of hybridisation are providing insight into the adaptive capacity of *Xanthium* as a worldwide coloniser of habitats disturbed by man. In India the diversity of photoperiodic responses[6,7] can be explained as the result of hybridisation between day neutral indigenous plants and plants with photoperiodic responses introduced from America[11–13].

I thank Drs A. Lang, D. Löve, P. M. Ray, F. B. Salisbury, G. L. Stebbins, and J. A. D. Zeevaart for their advice. Dr Löve has examined burrs of most of the parental plants and many of the hybrids and has agreed with the treatment of the morphological complexes.

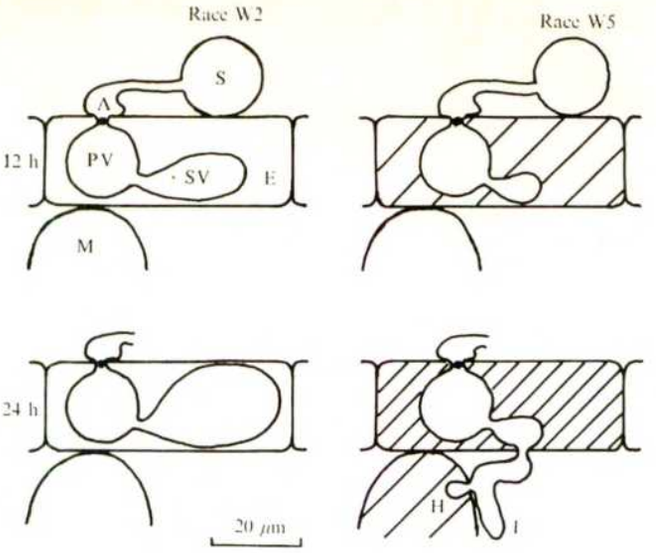

Fig. 1 Diagrammatic representation of the development of a compatible race (W2) and an incompatible race (W5) of *Bremia lactucae* in the lettuce cultivar Avondefiance. Primary and secondary vesicles are drawn to scale, measurements being derived from the means of ten replicates. Shading represents the extent of granulation and melanisation of the host cytoplasm. S, Spore; A, appressorium; PV, primary vesicle; SV, secondary vesicle; I, intercellular hypha; H, haustorium; E, epidermal cell; M, mesophyll cell.

Hypersensitivity as the primary event in resistance to fungal parasites

The hypersensitive reaction of plants to infection by incompatible strains of biotrophic fungi (organisms which, as parasites, derive their nutrients from living tissues[1]) involves the rapid necrosis of one or more cells at the penetration site, accompanied by restriction of the invading fungus. It is generally believed that this reaction by the host leads to a disruption of nutrient supplies to the fungus and the production of fungitoxic metabolites (for example, phytoalexins), resulting in the cessation of hyphal growth[2]. This traditional view has, however, been challenged by Brown *et al.*[3], who have suggested that the hypersensitive reaction of wheat to rust fungi is not the cause, but a consequence, of the earlier inhibition or death of the invading fungus. Király *et al.*[4], on the basis of indirect evidence, have extended this suggestion to include the resistance of bean to *Uromyces phaseoli* (rust) and potato to *Phytophthora infestans* (blight), and have questioned whether the term 'hypersensitive reaction' of hosts in connection with plant resistance has been correctly used in the past. Since this is a continuing debate among plant pathologists, we consider

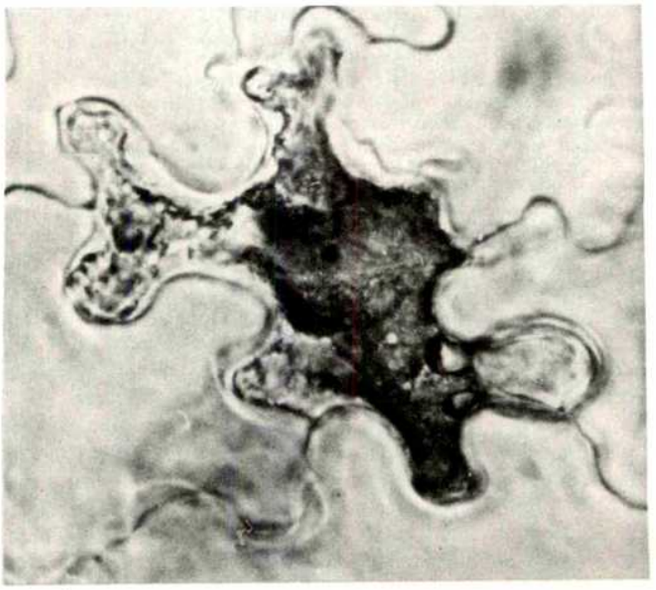

Fig. 2 Surface view of the hypersensitive reaction of an epidermal cell of the lettuce cultivar Avondefiance 60 h after inoculation with the incompatible race W5 of *Bremia lactucae*. Cells adjacent to the infected cell are apparently unaffected.

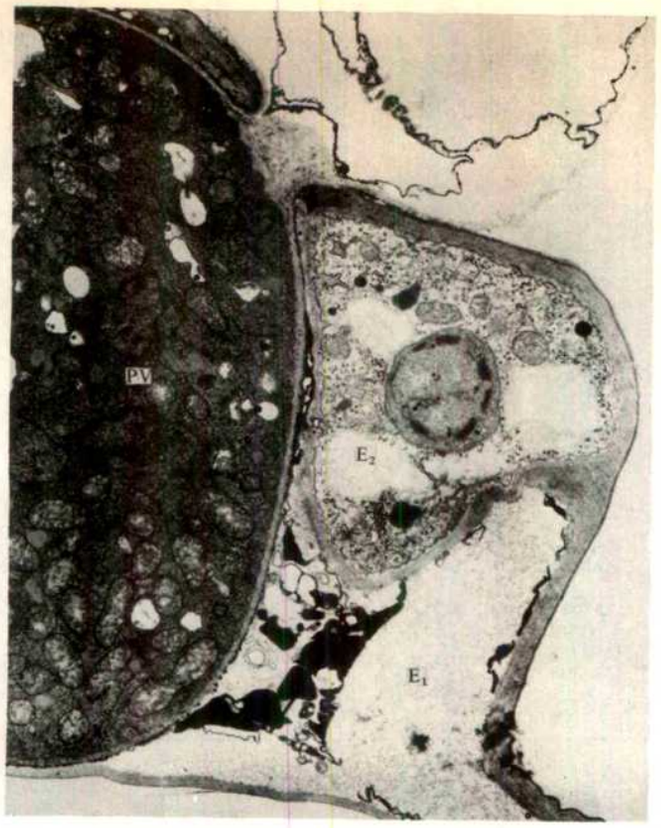

FIG. 3 Electron micrograph showing a primary vesicle (PV) of an incompatible race of *Bremia lactucae* (race W5) in an epidermal cell (E_1) of the lettuce cultivar Avondefiance. Note the complete disruption of the membranes and cytoplasm of this cell (arrowed) and the apparent normality of the cytoplasm of the fungus and the adjacent, non-penetrated cell (E_2).

it pertinent to report here information which accords with the traditional view of the significance of the hypersensitive reaction. We show that in the resistance of lettuce (*Lactuca sativa* L.) to incompatible races of the downy mildew fungus *Bremia lactucae* Regel, death of penetrated host cells is the primary event, preceding the cessation of fungal growth by several hours.

During a study of the interaction between four races of *B. lactucae* and five cultivars of lettuce we observed that incompatibility was normally accompanied by a hypersensitive reaction in the host. The time course of the infection process was followed in detail after inoculating the abaxial surfaces of cotyledons of the lettuce cultivar Avondefiance with aqueous suspensions of conidia of *B. lactucae* race W2 (compatible) or W5 (incompatible). Light microscopy showed that the germ tubes of both races penetrated epidermal cells and by 12 h after inoculation had produced a spherical primary vesicle and an elongated secondary vesicle[5]. The primary vesicles of both races developed at the same rate. Growth of the secondary vesicle of the incompatible race, however, was markedly retarded compared with that of the compatible race (Fig. 1); the former was fully expanded (5×9 μm) by 12 h and the latter continued to enlarge for 24 h, reaching a final size of 14×26 μm. Observations at intervals up to 60 h showed that the compatible race caused no necrosis of the epidermal cells it penetrated. In contrast, the epidermal cells entered by the incompatible race showed progressive granulation and melanisation, although adjacent non-penetrated cells remained apparently unaffected (Fig. 2). From 24 h onwards, the compatible race formed an intercellular hypha giving rise to an extensive mycelium bearing haustoria. The incompatible race, however, initiated an intercellular hypha as early as 12 h, although this stopped growing by 24 h, after producing approximately three haustoria which caused a hypersensitive reaction in the cells they entered.

Cytological examination of both strains of the fungus from spore germination onwards showed that for the first 12 h there was no significant increase in the number of nuclei per colony. Thereafter, the number of nuclei increased in colonies of the compatible but not of the incompatible race. Nuclear division in *B. lactucae* is probably dependent on the establishment of a biotrophic relationship between host and fungus and the failure of the nuclei to divide in the incompatible race is a reflection of its inability to establish such a relationship.

Electron microscopy of infected cotyledons showed that in compatible interactions the host cell plasmalemma was invaginated to accommodate both the primary and secondary vesicles of the fungus, and there was no evidence of cytoplasmic damage[5]. In contrast, within 4 h the membranes and cytoplasm of epidermal cells penetrated by the incompatible race were severely disrupted (Fig. 3), although adjacent cells were apparently normal. The fungal cytoplasm also appeared perfectly normal at this time, being dense with apparently functional organelles.

These observations make it clear that the primary event in the interaction between Avondefiance and the incompatible race W5 of *B. lactucae* is the rapid death of the penetrated cells. The fungus continues to grow for at least 12 h after this, although it too eventually dies. The most likely cause of death of penetrated cells is a rapidly-acting toxin produced by the healthy fungus during the early stages of the interaction. Since adjacent cells are not killed, this toxin could be a molecule which is closely associated with the fungal cell wall, or which cannot diffuse in sufficient quantity through host cell walls.

In the specific example reported here, light and electron microscopic studies during the very early stages of the host–parasite interaction have produced a clear sequence of events during the hypersensitive reaction to infection by an incompatible fungus. It is likely that more than one mechanism for hypersensitive resistance in plants exists, but it would be interesting to know whether the contradictory conclusions of earlier studies[3,4] would be supported by microscopic observations during the early stages of the host-parasite interactions.

Experimental details of this report will be published elsewhere. We thank Professor P. W. Brian, for discussions.

New species of *Dryopithecus* from Kenya

Two new species of Pongidae, assigned to a new subgenus of *Dryopithecus*, are here described for the first time. These assignations are based mainly on new specimens discovered recently in Kenya, but some other specimens[1,2] are reassigned to the hypodigms of the new species. A more complete revision of the African early Miocene dryopithecines is in preparation.

Three species of *Dryopithecus* from East Africa—*D. africanus*, *D. nyanzae*, and *D. major*—have been accepted as valid species, and are grouped in the subgenus *Proconsul* (Hopwood)[3]. The two new species are grouped in another subgenus to distinguish them from the other African and Eurasian species of *Dryopithecus*. Moreover, *Limnopithecus legetet*, which has pongid affinities, both dentally and postcranially, and which differs mainly in size from the species of *Dryopithecus*, is also included in the Dryopithecinae. As the subgeneric affinities of this species are not clear it seems best at this stage to retain it as a separate genus of the Dryopithecinae. The other species assigned to *Limnopithecus*, '*L. macinnesi*', is retained in the Hylobatidae[1], so that it will be necessary to change the generic classification of this species. Thus there are two genera and six species of the Pongidae, Dryopithecinae, and one genus and species of the Hylobatidae, now recognised in the early Miocene of East Africa. The dentitions of the six dryopithecine species range in size from slightly smaller than those of the gibbon to about the size of those of a female gorilla.

Le Gros Clark and Leakey[1], when describing a maxilla fragment assigned to *Proconsul africanus* (field no. 415'47, KNM-SO 401), noted its aberrant features and stated that further similar material might make a new species necessary. Such new material came in Leakey's 1966 collection from Songhor in the form of a complete palate which I described in 1970 (ref. 2). At that time, as my study of the total sample was incomplete, I referred it to *Proconsul* sp. with the intimation that it probably belonged to a new species; this views is now found to be justified. The entire dentition, based on a total of of 79 specimens, is known and a complete half mandible has just been found at Songhor (KNM-SO 1112) so that the lower dentition is now as well known as the upper. This new specimen is here described as a new species, *Dryopithecus gordoni*.

Another recent discovery, this time from Rusinga Island, was a partial maxilla and upper dentition (KNM-RU 2058) which, although almost identical morphologically to *D. gordoni*, is much smaller. Unfortunately the smaller form is known only from the upper dentition and from only seven specimens. One of these, a maxilla fragment (field no. R 593'47, KNM-RU 1778), had previously been allocated[1] to *L. macinnesi*. There are no morphological differences between these small specimens and *D. gordoni*, but examination of the ranges of variation and significance tests established that samples are sufficiently different in size to make it unlikely that they come from one population ($P < 0.001$). The smaller sample is therefore described here as a new species, *Dryopithecus vancouveringi*.

The similarity of the two new species is illustrated in Fig. 1 where the upper tooth rows have been reduced to the same P4-M3 length. For comparison the equivalent tooth rows of *D africanus* and '*L. macinnesi*', which correspond most closely in size to *D. gordoni* and *D. vancouveringi* respectively, are

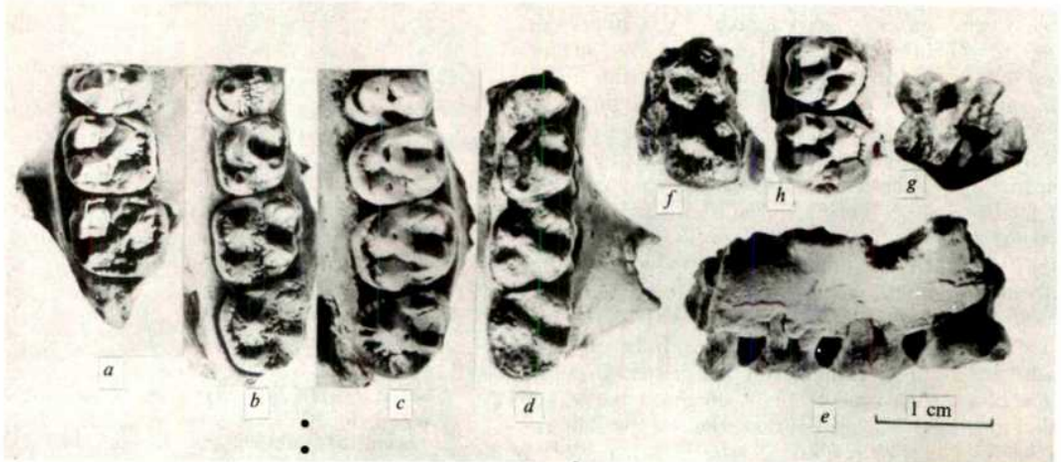

FIG. 1 Occlusal views of upper dentitions. *a*, *D. africanus*, P4-M2, KNM-RU 2036; *b*, *D. gordoni*, P4-M3, KNM-SO 700; *c*, '*L. macinnesi*,' P4-M3, KNM-RU 1849; *d*, *D. vancouveringi*, P4-M3, KNM-RU, 2058; *e*, *D. vancourveringi*, P4-M3 (lateral view), KNM-RU 2058; *f*, *D. vancouveringi*, dp4-M1, KNM-RU 1778; *g*, *vancouvering*, dp4-M1 (lateral view), KNM-RU 1778; *h*, *D. major*, dp4-M1, KNM-SO 542. *d*, *e*, *f*, and *g* are all to the same scale as indicated, but the other specimens are reduced or enlarged to the same P4-M3 length as in *d*, or to the same dp4-M1 length as in *f*.

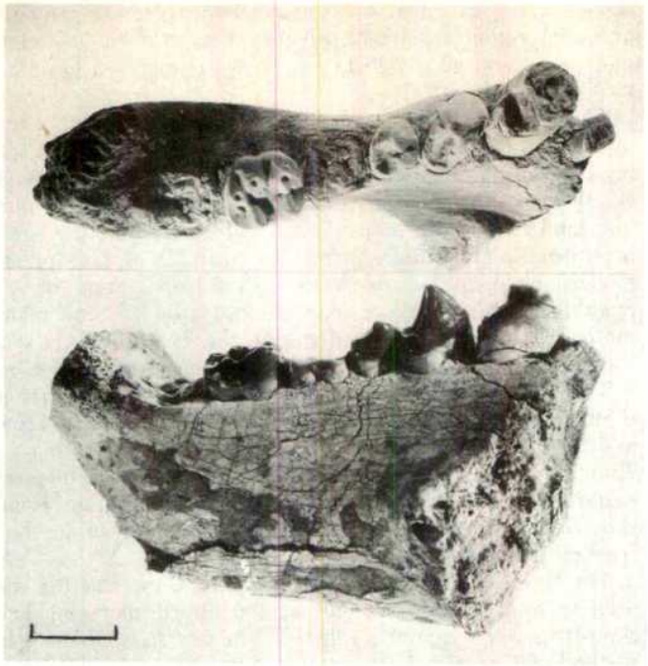

FIG. 2 Occlusal and lingual views of the new mandible of *D. gordoni* (KNM-SO 1112).

also included. The figure illustrates the distinctive morphology of the two new species, particularly the molariform premolars, with large lingual and distal cingula, the elongated upper molars (also shown in the tooth dimensions given in Table 1), the large size of the protocone on the upper molars, and the increase in molar size from M1 to M3. Other features not immediately evident from the figure are the lowness of the molar and premolar cusps, the degree of wrinkling of the occlusal surfaces, and the relatively marked wear gradient on the molars. Other features which are present in the larger sample of *D. gordoni* but which are not known for *D. vancouveringi* include the remarkably high-crowned structure of the incisors and to a lesser extent the canines, the elongated and wrinkled lower molars, and the large size and depth of the mandible (Fig. 2). In all these shared features, the two species differ from all other species of *Dryopithecus*, so they are here combined into a single higher taxonomic category. Since recent usage in pongid taxonomy has been to recognise subgeneric rather than superspecific groups[3], this category was selected, and the name *Rangwapithecus* was chosen. When more is known about the Eurasian dryopithecines, and in particular when better upper dentitions and skulls are found, it may well be necessary to resurrect some of the genera sunk by Simons and Pilbeam[3], and this may include establishing *Rangwapithecus* as a valid genus.

Diagnosis of the two new species are as follows:

Subgenus: *Rangwapithecus* subgen. nov.

Diagnosis: species approximating in size to the gibbon and siamang. Incisors high crowned and relatively very narrow compared with (*Proconsul*) and (*Dryopithecus*). Upper molars and premolars elongated, the molars usually longer (mesiodistally) than broad, low cusped and the occlusal surface often has more secondary wrinkling than in (*Proconsul*). Upper molars increase in size from M1–M3 and premolars from P3–P4 unlike both (*Proconsul*) and (*Dryopithecus*). No reduction of M3. Lower molars and premolars also elongated. The molars have a marked wear gradient, such that M1 may have dentine exposed on the occlusal surface when M3 is only just coming into wear, unlike the condition in (*Proconsul*) and (*Dryopithecus*). Strong lingual cingula are developed on all the upper molars and premolars, and the premolars also have a prominent distal cingulum. Zygomatic process is set very low over M1/2. The floor of the maxillary sinus is greatly extended.

Contained species: (1) *D. gordoni* sp. nov. (2) *D. vancouveringi* sp. nov.

(1) *Dryopithecus* (*Rangwapithecus*) *gordoni* sp. nov.

Holotype: KNM–SO 700 maxilla with complete upper dentition except for the incisors. Housed at the Kenya National Museum, Nairobi.

Locality: Songhor, Kenya.

Reference: Andrews[2], not named but referred to *Proconsul* sp. (Individual specimens attributed to this taxon have been assigned in the literature to *Limnopithecus macinnesi*, *Proconsul africanus* and *Proconsul nyanzae* (ref. 1).)

Distribution: Early Miocene. Most common at the Tinderet site of Songhor but a few specimens are known from the Rangwa sites of Rusinga and Mfwangano Islands.

Hypodigm: seventy-nine specimens which cover the entire dentition, the mandible except for the ascending ramus, the maxilla and palate. A few postcranial fragments may belong to this species. BM(NH) M 16637; KNM–RU 1686, 1692, 1722, 1768, 1833, 1894; KNM–MW 52; KNM–SO 89, 373–5, 377, 383, 401, 419, 420, 428, 434, 445, 449, 450, 463, 464, 467, 473, 475, 486–8, 507, 521–3, 531, 540, 550–3, 555–63, 575, 577, 578, 583, 588, 590–3, 700, 904–9, 921, 923–5, 930–2, 938, 943, 945, 948, 1081, 1112, 1225.

Diagnosis: a species of *Dryopithecus* intermediate in dental size between the siamang and pygmy chimpanzee; similar in size to *D. africanus*. Upper teeth similar to those of *D. vancouveringi* as described in the subgeneric diagnosis, differing only in larger size. In the lower dentition the incisors are very high crowned and narrow; the canine is high crowned and bilaterally compressed; the P3 is very bilaterally compressed with nearly parallel buccal and lingual sides; the P4 is elongated; the M1–M3 are also elongated, the cusps are low, the buccal cusps are divided by deep buccal sulci like the condition in the gorilla, the occlusal ridges and buccal cingulum are poorly defined, and secondary wrinkling is often present. Mandibular body and symphysis relatively deep and robust, prominent superior transverse torus, no inferior torus. P3–M3 lengths are, upper 40 mm and lower 44 mm for single specimens. Upper M1–M3 length is 29 mm. Named in honour of H. L. Gordon, formerly Government Medical Officer at Koru, who collected many of the early specimens at Koru.

(2) *Dryopithecus* (*Rangwapithecus*) *vancouveringi* sp. nov.

Holotype: KNM–RU 2058 left maxilla with crowns of P4–M3. Housed at the Kenya National Museum, Nairobi.

Locality: Rusinga Island, Kenya.

Distribution: Early to ?middle Miocene at the sites centred on Rangwa: Rusinga and Mfwangano Islands; and the Tinderet site of Songhor. It also may occur at Maboko Island.

Hypodigm: seven specimens which cover only the upper postcanine dentition and parts of the maxilla. Also referred provisionally to this species are three specimens from Maboko Island, KNM–MB 53, 125, 148. KNM–RU 1778, 1801, 2058; KNM–MW 48; KNM–SO 942, 944, 1134.

Diagnosis: a small species of *Dryopithecus* approximately the dental size of the siamang. It is like *D. gordoni* in morphology, as defined in the subgeneric diagnosis, but differs from it in size. The M1 is significantly different from the M1 of *D. gordoni*. The upper tooth row lengths are M1–M3, 22 mm and P3–M3, estimated 31 mm for a single specimen. Named in honour of Judith and John Van Couvering who found the type specimen in 1968 at the Kaswanga Point deposits of Rusinga Island.

The six species of dryopithecines apparently represent a Miocene radiation of the Pongidae in Africa. There are several degrees of differentiation between the species. The species pairs *D. nyanzae*/*D. major* and *D. gordoni*/*D. vancouveringi* probably represent near contemporary speciation, inasmuch as the members of each pair are largely allopatric in distribution and differ from each other principally in size. *D. africanus* is much more distinct, both in size and morphology, from the *D. nyanzae*/*D. major* pair, and it is sympatric with *D. nyanzae*: it is probable that it represents an older stage in speciation. Finally, the distinctive morphological difference between the species assigned to the two subgenera and genera must represent a still more ancient divergence.

The Miocene proliferation of pongid species in Africa seems strange in the light of the distribution of present day African pongids. Rather, closer evolutionary parallel might be with the later Cainozoic radiation of African cercopithecine monkeys, which are even more diverse than were the Miocene pongids. The fossil pongids are known only from one corner of their range in Africa; it seems unlikely from geographical

and palaeogeographical evidence that East Africa represented the centre of the Miocene pongid radiation, and the main centres of distribution were more probably in West and Central Africa (as are those of modern monkeys). No Miocene pongids have been recovered in these regions, but it is quite possible that if they were, the pongid radiation would be seen to be at least as rich and diverse as is the cercopithecine radiation of today.

The relationship of these fossil hominoid primates with the living ones remains uncertain. In my opinion it is no longer feasible to suggest direct ancestral-descendent relationships between fossil and living species[4]. Presumably one or more of the Miocene species was ancestral to the later pongids, but which this was, and whether one or more species was also ancestral to the Eurasian dryopithecines, can not be known from the available evidence.

I thank Drs D. R. Pilbeam and A. C. Walker for help with the preparation of this note. I also thank the Wenner-Gren Foundation for Anthropological Research for financial support, the Boise Fund for support of field work and the Museum Trustees of Kenya for permission to work on this material.

Hair of the mammoth

THERE have been few detailed studies of the frozen remains of woolly mammoths (*Elephus primigenius*)[1]. Here I describe a study of evolutionary change based on the grouping of the hair follicles and the distribution of hair diameters. This approach has hitherto been possible only with domestic animals[2].

The ancestral elephant *E. meridionalis*, a warm latitude forest dweller of the Early Pleistocene, gave rise to two lines. One remained in the same environment and underwent only moderate evolutionary change, giving rise to the straight-tusked *E. antiquus* of the Middle and Late Pleistocene. The other line evolved more rapidly, passing through two species stages in the same time; *E. trogontherii*, a cool steppe dweller of the Middle Pleistocene, and *E. Primigenius*, the woolly mammoth of the Arctic tundra in the Late Pleistocene[1].

A notable adaptation of the mammoth to a cold climate was the development of a long, dense coat. The ancestor of the elephants must have had hair, but it may already have been as much reduced in *E. meridionalis* as it is in modern elephants. The coat of the mammoth is therefore likely to represent a redevelopment of hair, and not the retention of the ancestral condition. What was the structure of the mammoth coat, and what follicle grouping was involved in its development?

The coat of the mammoth has been described as having an underwool, a longer, coarser yet fluffy outer hair, and an even longer, scarcer, bristly but flexible hair[3] (Table 1). Another account described the underwool as soft and reddish, one kind of hair as coarse, wiry and black, and the other as brownish and much finer[4]. The scarcity of hair in the modern elephant is associated with a corrugation of the epidermis, and a lack of skin glands. Although the mammoth, too, apparently lacked glands, the increase of the hair was associated with a loss of the epidermal corrugation[5].

The ancient material available comprised some hair from a Siberian mammoth about 10,000 yr old sent from Moscow, and three samples of skin from the Liakhov mammoth (No. 1912-23) in the Palaeontology museum, Paris. The modern material for comparison was some elephant leather, some skin from an African elephant, and two specimens of hair from an Indian elephant.

The International Standards Organisation method 181 was used to measure the diameter of 100 fibres from each hair sample in whole mount[6], and the skin was sectioned by the method of Ryder and Stephenson[6], after treatment in Sandison's softening fluid[7,8].

It has been concluded[5] that no fading has occurred in the colour of mammoth hair. By electron spin resonance[9] the Moscow sample had been shown to have a concentration of free radicals equal to that in white wool, and so it was concluded that it had been white, and that the yellow-brown colour was merely discoloration. It seems unlikely that the mammoth was in fact white, since stomach contents indicate that it was vegetarian like the musk ox[1], and only predators or prey in the Arctic turn white in winter.

Although I was unable to detect pigment granules, the coarser mammoth hairs were darker. A feature common in double-coated mammals, this suggests that the hairs were originally pigmented, the pigment having become diffuse with time. Chemical degradation has been demonstrated in mammoth hair[10].

The hair diameter distribution of the ancient and modern samples is shown in Table 2. The Moscow sample had a double coat but owing to its irregular nature, the length of the underwool could not be measured. The outer hair was shorter than the shorter (20 cm) of the two lengths quoted[4] although not much less than the longest (12 cm) in Neuville's unknown specimen[5] (Tables 1 and 2). The lack of the longest hairs (45 cm) cannot be due to breakage, because no hairs of commensurate coarseness were present in either the Moscow or Liakhov samples (Table 2). Their absence could be due to shedding some time before death, which could imply death at the end of winter, and not at the end of summer as previously surmised[1].

The three samples of flank skin were of similar thickness: fresh, 23 mm; leather, 22 mm; Liakhov, 22 mm (leg only 12 mm). It was impossible to section the leather. The fresh

TABLE 1 Previous measurements

Source	Specimen	Underwool length	Outer hair length: Short	Outer hair length: Long
Lang[3]		5 cm	45 cm	longer (diameter ≤ 1 mm)
Quakenbush[4]		3.8 cm (red)	15–20 cm (brown)	45 cm (black and bristly)
Neuville[5]	unknown	2.5–3 cm (40–75 μm diameter) blond	12 cm (90–325 μm diameter) red or black	
	Liakhov (leg)	light yellow	25* cm light red (blond) at base	

* Hair length confirmed in present study (see Table 2).

TABLE 2 Coat measurements

Specimen	Length (cm)	Diameter (μm) Range	mode	Mean ± s.d.	CV (%)	Distribution
Moscow	10	24–132	40	56.8 ± 24.7	43.5	skewed-to-fine
Liakhov (leg)—straight	25	26–110	40	50.0 ± 15.8	31.5	skewed-to-fine

Indian elephant (head)	15		~500			

* Although to naked eye the few coarser ones stand out among the remainder

skin confirmed the corrugation[5] of the epidermis, which had closely-packed pillars about 1 mm high resembling the villi of the intestine but hexagonal in section. The pillars were grouped into clusters separated by channels, and the hairs emerged at the junction of several channels. The hair density was 2 to 3 cm^{-2}, and were of two sizes, suggesting origination from primary central (larger) and primary lateral (smaller) follicles. The presumed centrals were deeper than the presumed laterals, extending 4 to 5 mm into the skin.

Sections cut parallel to the skin surface revealed sparse, round, non-medullated hairs with no glands or erector muscles. The follicle density was 6 cm^{-2} (that is, two groups). The trios had a V configuration (90° angle) with the larger central follicle at the base and the two laterals at the tips of the arms, which were 2 to 5 mm long. At least one central follicle had a surrounding sinus which suggests that it was a tylotrich (special sensory) follicle[11].

The best sections of the Liakhov skin came from the leg. The collagen fibres were very coarse, and stained green with picro-indigo carmine, as found previously with undecayed remains[8]. Follicle debris stained maroon with basic fuchsin. The hairs exhibited slight basophilia, staining orange rather than yellow, with picric acid and fuchsin.

The hairs in the leg skin were noticeably circular in section and of two widely differing sizes (outer coat and underwool). One fine group of 15 ranged from 48 to 76 μm in diameter (mean 62 μm), and a coarser group of five ranged from 88 to 180 μm (mean 129 μm). Both groups were thus coarser than the similar hairs measured immediately above the skin surface (Table 2).

There were a few follicle groups with trios of larger 'primary' follicles in which the laterals were 0.2 to 0.3 mm from the central. Between the central and the lateral were smaller 'secondaries' (Fig. 1). Distributed at random were a few even larger empty follicles, one of which had a collapsed lumen measuring 140 × 400 μm. These could be the source of the much larger hairs recorded by previous workers.

The central hair of the 'primary' trio in Fig. 1 is 68 μm, whereas the lateral is 128 μm, in diameter. The 'secondaries' between are 50, 56 and 62 μm in diameter. The hairs within the skin seemed to have narrowed preparatory to shedding, in spite of the observation that those above the surface were finer. For example, the hairs within the skin had only a tiny medulla, although there was little medullation in either the hair above the surface, or in that of the modern elephant. These hairs are remarkably coarse to lack a medulla. Neuville[5] mentioned elliptical as well as circular hairs, and variable medullation, although his measurements show that any medulla occupied no more than one-third of the width of the hair.

The Liakhov flank had more open connective tissue, and this seemed to be the cause of a loss of hairs during sectioning. No groups were evident but nine hairs ranged from 60 to 80 μm in diameter (mean 70 μm).

In attempting to draw conclusions from this evidence, the tendency is to think of the modern elephant as having lost the hair seen in the mammoth, but the modern elephant must be regarded as the ancestral form. Thus the ancestral elephant probably lacked skin glands and hair erector muscles, and it seems that these were not developed by the mammoth. Erector muscles, but not the skin glands, would have been advantageous in a cold climate. Why the elephant lost these glands when they are retained in the similarly 'hairless' rhinoceros is not clear.

From the earlier descriptions it seemed that the longest and coarsest hairs of the mammoth could have grown in the central follicles of primary trios, and so be 'bristles', while the shorter and less coarse hairs might have grown in the two laterals, being therefore 'awns'[6]. Although the modern elephant has central and lateral primaries, the hairs differ little in size, and both compare with the longest and coarsest 'bristles' of the mammoth. Evidence of even larger follicles was found in the mammoth, but these did not seem to belong to trio groups. Since at least some of the centrals in the elephant may be tylotrich follicles, the largest hairs of the mammoth could also be tylotrichs. The development of these sensory hairs in the elephant could be associated with the thick and apparently insensitive epidermis, and they could have been retained in the mammoth. The mammoth acquired a greater 'primary' follicle density not only by reducing the distance between the central and lateral follicles within trios, but by reducing the distance between the groups. The resulting greater hair density was associated with a reduction in the hair diameter of the 'primaries' (Table 2), which is a common phenomenon in sheep[8].

The modern elephant lacks an undercoat and so has none of the smaller secondary follicles that are developed later than the primaries. Such an adaptation to a hot environment is seen in the domestic 'hair' sheep (for example, the southern Desert type of India) which has less underwool as a result of a reduction in the number of secondary follicles[2]. The mammoth redeveloped an undercoat by the acquisition of smaller follicles lacking in the elephant (Fig. 1).

It is tempting to regard these smaller follicles as true 'secondaries', having developed later in the foetus, but unfortunately the lack of glands removes one distinguishing

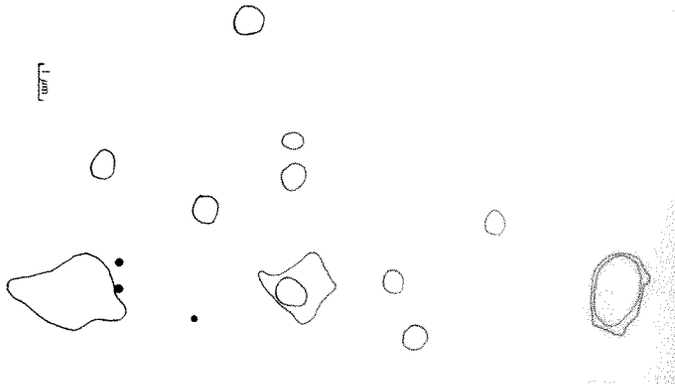

FIG. 1 Tracing of hair group in skin from leg of Liakhov mammoth.

feature[6]. The undercoat usually forms a distinct group of hairs in the diameter distribution which are separated by a wide gap from the much coarser outer coat hairs, as, for example, in the wild sheep[2]. In the mammoth (Table 2) it is difficult to detect any gap, so that the diameters seem to have a continuous distribution.

It may be therefore that once secondaries have disappeared in evolution, they cannot be redeveloped, and so any new undercoat must be formed by increasing the number of follicles, and extending the diameter range, as seems to have happened in the mammoth. An objection to this interpretation is that the size difference between the primaries and secondaries is thought to be due to their development at different times and to follicle competition[6]. If the smaller follicles of the mammoth were developed later, they could therefore be regarded as secondaries.

I thank Dr M. R. Brambell of London Zoo and Mr R. E. Chaplin of Edinburgh Zoo for supplying samples of modern elephant hair, Dr S. K. Eltringham of the Uganda Institute of Ecology for some elephant skin, Dr L. Ginsburg of the Palaeontological Museum, Paris for mammoth skin, H. B. Scott and F. M. Hay for technical assistance, and Dr G. C. Priestley for comments on the manuscript.

Note added in proof: After this letter had gone to press two more small samples were received from the USSR. Seven hairs from the Levar mammoth ranged from 14 to 39 cm in length, and from 98 to 260 μm in diameter with a mean of 179 μm. Three hairs from the Bereleh specimen ranged from 35 to 50 cm in length, and from 240 to 380 μm in diameter. The underwool of this sample ranged from 20 to 46 μm with one hair 70 μm in diameter, and an overall mean of outer hairs and underwool of 57 μm. These are evidence of the longer and coarser hairs mentioned in previous reports, but not found in the other samples of the present study.

Kinetic Cyclopean effect

While watching noise displayed on a television screen recently I noticed a visual effect which I report here. As normally viewed, displays of video noise ('snow') have the appearance of fields of small speckles which seem to dart about at random. When, however, the noise is viewed monocularly, the texture of the field seems finer and the speckles more nearly static. The display seen monocularly has the appearance of a field of smaller speckles which scintillate *in situ*. I have shown the effect to about ten friends and colleagues, without telling them what to expect. All noticed some difference between binocular and monocular viewing and several promptly described exactly what I had seen. In general, the size change was more consistently reported than the motion change.

I have made a rudimentary effort to explore the effect using a noise display generated by passing the green (514 nm) beam of an argon-ion laser through a pair of ground glass plates, one of which could be translated at a controlled speed. The speckle pattern so generated was projected on a screen. The resulting field of wideband, randomly changing visual noise bore a strong resemblance to television 'snow', though its statistics were not identical[1]. Under the conditions of the arrangement the speckle pattern produced by interference at the retina was so fine that it was nearly invisible, and so could not be confused with the intended display.

The following observations were made by three people. (1) The difference between monocular and binocular viewing was clearly evident, and resembled the effect obtained with the television screen; excessively rapid translation of the ground glass, however, did diminish the effect. (2) There was no difference between monocular and binocular viewing appearances of the stationary noise field obtained when both ground glass plates were still. (3) The effect could be obtained when the images in the left and right eyes were uncorrelated. Such images were obtained by presenting a different portion of the display to each eye using cardboard tubes to facilitate binocular fusion. (4) The effect could also be obtained when half the visual field of one eye was blocked by a card. In this case, one half of the field consists of the noise display as seen monocularly, and the other half consists of the same display as seen binocularly.

The last observation indicates that the effect is not induced by any process occurring in the eye itself, such as a transient misfocussing caused by the change from one mode of viewing to the other. The effect is therefore Cyclopean[2] in nature. Since it can only be seen in a non-static visual noise field, the classification 'kinetic Cyclopean effect' seems appropriate.

That the effect can be obtained whether or not the noise is binocularly correlated might suggest that even when the binocular images of the noise fields discussed here are correlated, they in some way exceed the ability of the visual processor to perceive the correlation. In any case it is not clear why a planar field of randomly changing visual noise should not appear the same to two eyes as to one. An adequate explanation of this effect might yield new information about the functioning of the visual system.

Is keeping up getting you down?

As a professional, you probably find reading journal articles to be a stimulating, educational, pleasurable experience. But the job of digging through piles of journals week after week to find these articles is not. It's tiresome. Expensive. A time waster. And it's unnecessary.

ASCATOPICS® can make keeping up with the journal literature as easy as opening your mail. Each week it brings you a list of journal articles that relate specifically to your work. Automatically. Less than three weeks after the articles are published.

You simply tell us what topics you want to keep up with. (Order any of the 17 most frequently selected topics right now or send for the complete list). ASCATOPICS takes it from there. Then every week the ASCATOPICS computer system checks the latest issues of 3,500 of the world's most important journals in science and the social sciences. In seconds, it locates and prints out the titles, authors and journal citations of articles you ought to be reading.

So if keeping up has gotten you down, now's the time to let ASCATOPICS make life a little easier for you. Use the coupon to order any one of the ASCATOPICS listed or to get a complete list of topics you may select.

Express emotion

Darwin and Facial Expression: A Century of Research in Review. Edited by Paul Ekman. Pp. xi+273. (Academic: New York and London, December 1973.) $17; £8.

In recent years there has been a new spate of popular books dealing with man's animal origins. These, together with claims about racial differences in intelligence and the biological basis of sex differences, have reinstated the old 'nature-nurture' controversy within psychology, and have led to heated disputes which are unlikely to be scientifically fruitful so long as the question is seen in terms of absolutes rather than matters of degree. Ekman's collection of papers is therefore doubly timely. Not only does it assess the century of research which has followed Darwin's valuable and delightful book, *The Expression of the Emotions in Man and Animals*, but it also provides an object lesson in how the confrontation of genetic and environmental viewpoints can lead to advances beyond the usual, and vague, "interactionist' compromise.

Taken together, the chapters give a balanced picture of Darwin's general approach to the explanation of behaviour, his specific theories of expression, his research methods, and the data he collected. They show that his position was in fact a sophisticated one, although he emphasised the genetic links between animal and human expressions, and the apparently innate universality of many of our emotional responses. In fact he was sensitive to many methodological pitfalls in research on emotion that later investigators have often overlooked. The present volume presents what is, by and large, a vindication of Darwin's insights. It also shows that we are only just starting to make significant advances on what he discovered a century ago.

Ekman's collection concentrates on the face, mentioning other aspects of expressive behaviour and the structure of emotion itself only in passing. Of the four main chapters only that by Petrinovich takes a broader view, giving an interesting presentation of how Darwin's theoretical and methodological paradigms have influenced psychology and ethology, and emphasising the importance of a functional view of human activities which takes full account of their biological and ecological context.

Chevalier-Skolnikoff reviews research on primate expressions, discussing their determinants and functions and relating them to the evolution of facial musculature and of the nervous system. Charlesworth and Kreuzer review the development of expressions and their recognition in infancy and childhood, remaining firmly at the descriptive level because they believe there is too little data to support elaborate theorising. It must be said, however, that on the topics of infant social smiling and fear of strangers there are other data which do go some way beyond Darwin's work and surely permit some theorising about underlying processes.

The other major chapter is Ekman's thorough review of cross-cultural studies, although some other aspects of adult expression are scarcely represented in the book at all. Recent studies, especially his own, contradict the long-standing view of anthropologists that Darwin was wrong in claiming an innate basis for emotional responses. In both Western-influenced and isolated cultures 'basic' emotions like happiness, disgust, surprise, anger, sadness and fear are displayed and recognised in relatively universal ways. Ekman's major contribution is a theory which accepts an innate basis to the linkage between eliciting stimuli, felt emotions, and behavioural expressions, and yet can deal with individual and cultural variations by reference to learned 'display rules' and other complicating factors. Although his theory gives a plausible role to both nature and nurture, and is to be welcomed, it is unfortunate that he does not entirely do justice to the environmentalists.

In fact the book as a whole takes too little account of two important facts about expressive behaviour. One is that facial expressions occur in association with other bodily movements, vocalisations, and even speech. Such multi-channel activities are simultaneously organised at several levels of instantaneous and temporal structuring, as the linguistic anthropologists have correctly emphasised. The second, more crucial point, is that these behavioural performances normally occur within, and are perceived within, a context of continuing social interaction. In fact much non-verbal behaviour serves several functions other than the purely expressive one. Darwin was certainly aware of the first of these points, and would surely have been glad to accept the second, so it is a pity that Ekman's book lacks a further chapter on the empirical and theoretical evidence relating to them. In fact it is on these topics that the most interesting nature-nurture questions now rest.

Despite these strictures, and other minor defects of the volume, Ekman has produced a valuable book which should be widely read. The contributors' careful avoidance of undefined technical terms, coupled with its very general lessons, should extend its appeal beyond the confines of the specialist disciplines represented. It is therefore inexcusable that its absurdly inflated price should threaten to deter many readers who would learn much from it.

Ian Vine

Critical approach

Exercises in Chemical Physics. By J. R. Riter, jun. Pp xiv+313. (Gordon and Breach: New York and London, 1972.) n.p.

Significantly new ideas in science teaching are rare and by no means necessarily translatable into book form. Professor Riter's method consists in a kind of inspired exegesis of selected papers in his field, the broad and delightfully ill-defined area of chemical physics. The papers he treats, or perhaps one should say draws upon, all appeared in about the last ten years of the *Journal of Chemical Physics*, a convenience which by no means takes away from the author's breadth of vision. In all some 166 articles are discussed under headings which include: thermodynamics, quantum mechanics, statistical mechanics, rate processes, mass spectroscopy, infrared, optical, rotational and NMR spectroscopy and the states of matter.

I used the term 'inspired' above quite advisedly. Professor Riter's studies are far more than a simple run-down of the background theory followed by routine, examination-type questions. The content of each article and the student's awareness of it are continuously probed as the author puts questions, makes suggestions for further reading and points to cross-connections. The main results of the article are usually presented in facsimile and a short precis of its aims and achievements given; thereafter the student is asked to reflect, criticise, calculate and cross-refer—sometimes even invited to find mistakes in the original. The result, as will have been deduced from the number of papers given, is

extremely condensed; with almost every other sentence in some passages putting a question or making some pertinent demand on the student, the quantity of food for thought provided is enormous and quite out of proportion to what one would expect from a book of such modest size. That the result is not indigestible owes much to Professor Riter's sense of style and feeling for the subject matter. His questions have a provocative and searching flavour difficult to convey here, which would be altogether more cramped in a conventional textbook. There is a droll humour, an unwavering sense of relevance, an infectious but entirely mature enthusiasm for chemical physics as a field and a sympathy with the authors whose work is dissected in such fascinating detail.

This adds up to one of the most successfully achieved ideas in advanced teaching that I have seen in a long time, and one which could no doubt be copied, though perhaps not so suitably, in many other branches of science.

M. R. Hoare

The nature of sleep

The Functions of Sleep. By Ernest L. Hartmann. Pp. ix+198. (Yale University: New Haven and London, January 1974.) £3.50 cloth; £1.25 paper.

This is a short readable book which should often succeed in interesting and informing the non-expert as well as the specialist. The author has been a prominent worker and prolific writer in the field of sleep research for over a decade. The emphasis in much of the book is on his own sleep research findings and he concludes by advancing yet one more theory concerning the nature of sleep. This latter is contained within the now generally accepted proposition that sleep has a restorative and reprogramming function. In contrast to some others, Hartmann's view is that the former is associated with slow wave sleep wherein synthesis of protein, RNA and other macromolecules crucial to cerebral function occurs, while the latter process is related to paradoxical or D sleep which follows on slow wave sleep and within which reconstruction of memory at the synaptic level can then occur.

Hartmann builds up his case systematically in the early chapters. Other theories are given brief and initial attention before a series of chapters within the rump of the book is given over to the various experimental approaches that can be made. Sleep deprivation studies are presented as having proved to be of limited heuristic value. Consideration is given to his own investigations of personality differences between long and short sleepers, and also to the clinical correlates of variable sleep which include behavioural, affective, nutritional and occupational items. Some physiological and chemical accompaniments of the various sleep stages are described as are also the ways in which their manipulation can affect sleep in animal studies and the human. A brief but interesting chapter on the different kinds of tiredness and a final one in this section concerning the nature of dreaming serve to remind the reader of the author's firm clinical roots.

The final chapter of the book concerns the integration of his theory of sleep into a more extensive one concerning the nature of the mind and he outlines the possible chemical bases of a variety of psychological mechanisms. Although speculative, it also reflects an important attempt to mobilise psychoanalytic concepts in physiochemical terms in a way which opens up the prospect of experimentation.

For all its chauvinism this is an attractive monograph in which the author, from a position of wide experience in the field of sleep research, has come clean to stoutly defend his holistic and multi-faceted approach and the need for it at this stage in our attempt to understand the chemistry of mind.

The style in which the references are set out (placed at the bottom of each page as well as in an alphabetical list at the end of the book) also makes for easy reading.

A. H. Crisp

Text on bacteria

Fundamental Principles of Bacteriology. By A. J. Salle. Pp. x+1094. (McGraw Hill: New York and London, May 1973.) £8.85.

This book is intended for "introductory majors courses in microbiology or bacteriology". But although there are chapters on yeasts, moulds, bacterial viruses and viral diseases of man, it cannot be regarded as a satisfactory microbiology text because protozoa and algae are scarcely mentioned in their own right and because, in the chapters on various aspects of the environment, microorganisms other than bacteria are more or less completely ignored. The short chapter on associations of bacteria does not compensate for these shortcomings and the book must therefore be judged as a bacteriology text.

In the preface the author states that he "attempts to include only sound fundamental material" and that he places emphasis "on the use of chemistry for a clearer understanding of the composition of bacteria and the reactions they produce". The extent to which these aims are achieved varies, of course, but in some chapters there are striking differences in the treatment of comparable topics. For example, the composition and chemistry of the bacterial cell wall are inadequately treated. There is no mention of teichoic acids although the existence of these polymers is acknowledged in the previous edition. Does the author now doubt the soundness of the work on their composition and structure? In contrast, immediately following the section on the cell wall there is a comparatively full and satisfactory treatment of flagella.

Although the book has many illustrations of chemical structures and equations for reactions, often these do not add very much to the student's understanding of the processes in which they take part. Perhaps the most striking instance is in the chapter on enzymes, where there is a 30-page incomplete list of bacterial enzymes "to show how enzymes are named and classified". This is somewhat extravagant if space when many other topics could, with advantage, have been dealt with more fully.

In many instances archaic nomenclature is used. For example, although it is true that some bacteriologists are extremely conservative in the names they use for carbohydrates, surely nobody now uses 'levulose' (*sic*) in preference to 'fructose' these days, and even if they do it must be confusing for any student to find such inconsistent usage as ". . . sucrase hydrolyzes sucrose to glucose and levulose," (page 354). Another criticism is that some at least of the reading lists are not very well chosen.

The index is inadequate and the layout of the print on the page is irritating in that although there are large outer margins the print approaches the bottom of the page so closely as to appear to be in danger of falling off!

It is remarkable that although the first edition appeared in 1939 most of the one thousand or so pages of this the, seventh edition, are still by the original author. Collaborators are responsible for only four of the thirty-one chapters—some eighty-nine pages. It would perhaps have been better had more authors been involved, for clearly it is beyond the capabilities of any one person to be sufficiently up to date in the many different fields that are covered by this book to be able to extract and present the essential information from each area within the time scale required in the preparation of a new edition.

Of course there is a lot of sound, thoroughly well presented material but deficiencies and distortions of relative importance prevent it being a serious contender for selection as a text for an undergraduate course. Perhaps the nicest way to summarise is to adapt the comment made by one British ex-politician about a recently deceased ex-colleague, and say that it is not fundamentally a bad book.

R. C. W. Berkeley

Red algae

Biology of the Rhodophyta. By P. S. Dixon. Pp. xiii+285. (University reviews in Botany.) (Oliver and Boyd: Edinburgh, October 1973.) £5.

A COMPREHENSIVE review of the Rhodophyta has been wanted for some years now. Professor Dixon has presented an analysis of current knowledge of certain aspects of the biology of these intriguing algae, drawing on information published up to 1972. The clear purpose is to make the reader aware of the deficiencies in knowledge, as well as indicating the advances made.

Within the scope of the seven chapters there are four in particular which present concise and stimulating accounts of key areas in present day research on red algae: morphology, reproduction, life histories and systematics and phylogeny. The chapter on morphology is of especial merit as it illustrates the numerous modifications of the filamentous habit and the potential of further work on morphogenesis both experimentally and with field observations. These approaches enliven a topic all too often avoided by students. The chapters on reproduction and life histories set out clearly the areas of conjecture, fact and theory. Through all of these the author steers a steady course which leaves the reader with little doubt as to what is reliable in the mass of conflicting information. The lines of future research are also clearly shown. Although the deficiencies in some aspects of the classification system are recognised, the lack of credible alternatives at present is also underlined.

Here then is a book of fundamental importance to students (of whatever age) of red algae. Minor blemishes there are. There is some repetition in later chapters of points covered in the introduction. Many of the diagrams are 'old friends' and some new interpretations would have been valuable. Many readers will regret the lack of a chapter on ecology. But the basic value of the book to continuing studies on red algae cannot be overemphasised.

A. D. BONEY

Man and society

The Riddle of Man: An Introduction to Psychology. By Richard S. Lazarus. Pp. xii+628. (Prentice-Hall: Englewood Cliffs, NJ, January 1974.) $10.95.

THIS is an outstanding, balanced and humane multidisciplinary book which is much more than an introduction to psychology as its modest subtitle might suggest. The 'riddle of man' the book takes as its subject matter concerns man's biological nature and its interaction and interdependence with his social and physical environments.

Man's biological make-up is seen as influencing the social order he creates and in turn social patterns are shown to modify the way biological processes operate. But the author does not conceptualise man as a passive responder to environmental stimuli and he explicitly rejects the view that in order to understand human behaviour one has to examine it solely in terms of rewards and punishments which follow actions (as does Skinner). The author defines psychology as the science of behaviour and mental activity—a deliberate choice of words since he considers it as one of man's remarkable qualities that he not only acts but is an observer and critic of his own actions. Psychology is presented as one of many interrelated disciplines—biology, anthropology, sociology and economics, all of which attempt to contribute to an understanding of man and society. The author draws on all these sciences and borrows their insights but his focus is a psychological analysis of the individual's biological and social development, his internal motivation and overt responses, his mental and emotional states and his reactions to stress and change.

The book is unusual for a textbook in psychology in that it tells a coherent and compelling story; it addresses itself to some of the unsolved issues of current—and perennial—human concern and to this end has been organised around four key issues: the physical and social environments of man; the psychology of aggression; prejudice and intergroup hostility; and adaptation versus alienation. This book, then, is problem-centred and continuously forges imaginative links with the student's own world and experience. But, within this framework, it also introduces the reader to a great many basic psychological and social psychological processes, concepts and theories. It presents competing paradigms and theories and makes explicit their assumptions and consequences and hence challenges the student to come to his own conclusions and to forego a premature and too exclusive theoretical commitment of his own—be this a commitment to behaviourism or to Freud or to anything else. Thus, at all times the student is presented with scientific controversies which are patiently and skilfully explored to give the student a sophisticated grasp of the issues. Thus, for instance, in discussing the failure of individuals to cope successfully with the stress of living and to find inner harmony, both the 'illness model' and the 'social learning model' are examined as a basis for understanding adaptive failure.

This book is beautifully produced, superbly illustrated with imaginatively chosen photographs, cartoons and diagrams. A further feature are quotations in the margins from important primary sources and detailed notes on theoretical, methodological and empirical issues which provide a useful underpinning of the text.

HEDY BROWN

Semiconductors

Semiconductor Physics. By Karlheinz Seeger. Pp. xv+514. (Springer Study Edition.) (Springer-Verlag: Vienna and New York, 1973.) 430 schillings; 60 DM.

"THIS book has been designed primarily as a text-book for a three-semester, three-hour per week senior or graduate course in semiconductor physics for students in electrical engineering or physics"; to quote its preface. The course is no easy option, for the book covers with encyclopaedic thoroughness nearly every aspect of semiconductor physics, in breadth if not always in depth. After introductory chapters on elementary properties, band structure and semiconductor statistics, the following topics are discussed: charge and energy transport in a non-degenerate electron gas; carrier diffusion processes, with a brief treatment of transistors; scattering processes in a spherical one-valley model; charge transport and scattering in the many-valley model; carrier transport in the warped-sphere model; quantum effects in transport phenomena; impact ionisation and avalanche breakdown; optical absorption and reflection; photoconductivity; semiconductor light generation; surface properties; and miscellaneous semiconductors. The text is well illustrated with 372 figures, many taken from the literature. There are five useful appendices and author, subject and substance indices.

There are two features which are unusual in a book of this nature. Complete derivations, including the intermediate equations, are given in the text of the numerous mathematical relations. This feature, which is designed to assist the less numerate student, unfortunately increases the algebraic content of the book at the expense of its physics content. The second feature is the provision of over 650 references in the text, many of them to books of similar size. In most cases these references provide a useful supplement to information already given in the text. In some cases, however, they are used as a substitute for such information. The important semiconductor technique of zone refining is mentioned on pages 1 and 153. In the first case it is accompanied by a reference to three books and several other volumes, and in the second by a reference to a book in German. In neither case in any explanation given of the nature of zone refining, an omission ac-

ceptable in a research paper but not in a textbook.

Despite these blemishes, the book provides a well written, comprehensive account of the transport and optical properties of semiconductors, which should prove useful not only to 'senior or graduate' students, but also to research scientists in the area of semiconductor physics.

J. B. BIRKS

Leukocytes collecting

Chemotaxis and Inflammation. By Peter C. Wilkinson. Pp. viii+214. (Churchill Livingstone: Edinburgh and London, 1974.) £4.

THERE is an analogy between the way in which research on leukocyte chemotaxis has been conducted and the movement of leukocytes themselves. For years there was more or less random observation by pathologists, bacteriologists and immunologists, who reported chemotactic activity for neutrophils or mononuclear phagocytes in a variety of products of bacterial growth, tissue injury and immune reactions. A distinction was made between cytotaxins, which themselves stimulate the directional movement of cells, and cytotaxigens, which bring about a chemical change in non-chemotactic molecules, usually serum constituents, as a result of which cytotaxins are generated. From all this work a long list of chemotactic factors has accumulated, some of which are controversial.

Two technical innovations improved the quality of research in this field. One was the introduction of the Boyden chamber and developments of it which made observations on chemotaxis more quantitative. The second was the availability of new methods for purifying chemotactic factors such as complement components. At present research on chemotaxis is gaining fresh impetus. Random activity and accumulation of miscellaneous observations is now being replaced by studies directed towards the purification and characterisation of cytotaxins and ascertaining how they act on leukocytes. Although the progress so far made is limited, the direction is obviously right.

Some cytotaxins, such as α_s-casein and the cleavage products of complement components, C3a and C5a, have been identified and quite a lot is known about the chemical composition of casein and C3a. The first steps have been taken towards defining the physicochemical properties of a molecule that make it cytotaxic. Wilkinson's own research on the generation of chemotactic activity when proteins are denatured or coupled with acid anhydrides or other groups is a contribution in this direction.

It seems as though basic peptides with specific conformations, such as the arginine-rich C3a, or proteins with rather high concentrations of surface non-polar groups, such as α_s-casein and denatured or substituted proteins, are cytotaxic. Possibly the former interact with and cluster certain acidic glycoproteins in the surface of the leukocyte whereas the latter penetrate into the membrane of the leukocyte. Both could increase the permeability of ions, such as calcium, through the leukocyte membrane, thereby triggering chemotactic responses.

Books on chemotaxis are out of date and out of print. This year will see the publication of two books on chemotaxis, a multi-author volume edited by Sorkin and the shorter monograph by Wilkinson under review. The latter is a well written introduction to the subject which will provide enough information for all but specialists. Scotland is neutral ground in the skirmishes that have sometimes developed between Switzerland and the eastern seaboard of the United States, and Wilkinson provides a balanced appraisal of the situation. Where available information is confusing, such as in the role of cyclic nucleotides in the responses of leukocytes to chemotactic factors, this is plainly stated. Perhaps observations on activation of guanylate cyclase, too recent to be included by Wilkinson, will help to resolve the problem.

In any case, there is current interest in the motility of cells, which depends on an actomyosin system similar to that in smooth muscle, on mechanisms by which attachment of various substances to plasma membranes can trigger cellular responses and on the behaviour of embryonic and other cells in concentration gradients. These developments in cell biology should soon be applicable to chemotaxis. Wilkinson's book provides a useful summary of the first fifty years of research on chemotaxis and can also serve as an introduction to the next phase of development. Perhaps it will stimulate cell biologists to use leukocyte chemotaxis as a model system which is of interest in itself and also relevant to medicine.

A. C. ALLISON

Climatic change

Éléments de Paléoclimatologie. By Raymond Furon. Pp. 216. (Sciences de la Terre.) (Librairie Vuibert: Paris, 1972.) n.p.

THERE is a clear need for a new objective, systematic review of palaeoclimatology, but Furon's contribution, instead of improving on the three main books is more likely to retard this interdisciplinary science. It commences with a chapter of statements about the characteristics of present climatic zonation, but without emphasising the underlying causes, and is followed by an inadequate outline of uncomprehended theories that could cause climatic change. Forty-nine pages are given, according to the title, to methods of palaeoclimatology. They turn out to be seriously incomplete yet space is wasted returning to arguments about continental drift instead of making necessary qualifications to bald statements such as striated and polished stones proving a glacial origin; illite, mica and feldspars in shales associated with Carboniferous coal being incompatible with a humid, tropical climate; and so forth. The objective evaluation of climatic indicators should be possible irrespective of the status of theories of the Earth's surface evolution.

The second section comprises five chapters dealing with different time spans which contain patchy lists of stratigraphic features, only some of which are of palaeoclimatic usefulness—for example, the thickness of Mesozoic volcanics in Mozambique is surely less climatically significant than the coral reefs of the North American and European Permian that are neither mentioned nor shown on a map purporting to show their distribution. Despite his own warnings, the author interprets all occurrences of *Gangamopteris* and *Glossopteris* as indicating warm, humid conditions, and the interbedded glacial debris as always from mountain glaciers associated with an unexplained 300 million year climatic cycle of ice ages. He admits, however, to being "un peu troublé" by the absence of glacial evidence from continents north of the Tethys and sprinkles the section dealing with the Carbo-Permian of Europe with "climat chaude", "chaude et humide", and so on, sometimes based on the presence of evaporites, but often without specifying the evidence. Luckily, the data are plotted on maps using the present geography and so avoid arguments about reconstructions, which Furon disbelieves, and which even those on the plate-tectonic bandwagon must still regard as subject to review.

The 16 palaeoclimatic maps are regrettably small, less than 12 × 8 cm, so that symbols (often only one or two per map) often overlap areas far distant from the actual outcrop and are all the same size, irrespective of such factors as the thickness of the evaporites represented. There is no index, but quite long bibliographies follow each chapter. This arrangement leads to repetition, so that Furon's *La Paléogéographie* is listed five times but Termier and Termier's *Atlas de Paléogéographie* only appears once and Harland's work on the late Precambrian is not mentioned anywhere. Nonetheless, the bibliographies are the most useful part of this unsatisfactory book.

3 new Ciba Foundation Publications

Human Rights in Health

Ciba Foundation Symposium 23

1974. 314 pages.
Dfl. 39.00 (about: US$ 14.20; £ 6.00)
ISBN 90 219 4024 8

Contents:

Introduction (G. E. W. Wolstenholme and K. M. Elliott). Financial resources: present and future (Ch. Elliott). Water supply in developing countries (B. H. Dieterich). Domestic water: good or right? (G. F. White). Domestic water supplies for rural peoples in the developing countries: the hope of technology (I. Burton). Water supplies: the consequences of change (D. J. Bradley). The food potential (N. W. Pirie). Whither the food and population equation? (W. H. Pawley). Food supplies for physiologically vulnerable groups (D. B. Jelliffe and E. F. P. Jelliffe). Health services and medical education in China: a brief report (O. Mellander). The control of communicable disease: problems and prospects (G. Edsall). Cost-effectiveness and cost-benefit aspects of preventive measures against communicable diseases (B. Cvjetanović). The basic human right to the means of controlling fertility (D. M. Potts). Personal health care: the quest for a human right (M. King). Bottlenecks in implementation: some aspects of the Scandinavian experience (W. B. Eide, M. Jul and O. Mellander). General Discussion: Integration of Western attitudes and the responses of recipient countries. Conclusion (G. E. W. Wolstenholme). Biographies of contributors. Index of contributors. Subject index.

Aromatic Amino Acids in the Brain

Ciba Foundation Symposium 22

1974. 406 pages.
Dfl. 51.00 (about: US$ 18.60; £ 7.80)
ISBN 90 219 4023 x

Contents:

Chairman's introduction (R. J. Wurtman). Control of plasma amino acid concentrations (H. N. Munro). Amino acid transport in the brain *in vivo* and *in vitro* (A. Lajtha). Octopamine, phenylethanolamine, phenylethylamine and tryptamine in the brain (J. Axelrod and J. M. Saavedra). Tyrosine aminotransferase in the brain (P. Mandel and D. Aunis). Properties of pterim-dependent aromatic amino acid hydroxylases (S. Kaufman). The *in vivo* estimation of rates of tryptophan and tyrosine hydroxylation: effects of alterations in enzyme environment and neuronal activity (A. Carlsson). The regulation of tyrosine hydroxylase activity in adrenergic nervous tissue (N. Weiner, F.-L. Lee, J. C. Waymire and M. Posiviata). Nutritional control of the synthesis of 5-hydroxytryptamine in the brain (J. D. Fernstrom, B. K. Madras, H. N. Munro and R. J. Wurtman). The transfer of tryptophan across the synaptosome membrane (A. Parfitt and D. G. Grahame-Smith). Tryptophan concentration in the brain (A. T. B. Moir). Serum free tryptophan: control of brain concentrations of tryptophan and of synthesis of 5-hydroxytryptamine (G. L. Gessa and A. Tagliamonte). Fatty acids and the disposition of tryptophan (G. Curzon and P. J. Knott). Monoamine metabolites in the cerebrospinal fluid: indicators of the biochemical status of monoaminergic neurons in the cerebral nervous system (M. Bulat). Do tryptophan concentrations limit protein synthesis at specific sites in the brain? (S. H. Barondes). Aromatic amino acid supply and protein synthesis in the brain (S. S. Oja, P. Lähdesmäki and M.-L. Vahvelainen). Effects of amino acid imbalance on amino acid utilization, protein synthesis and polyribosome function in cerebral cortex (S. Roberts). L-Dopa, polysomal aggregation and cerebral synthesis of protein (B. F. Weiss, L. E. Roel, H. N. Munro and R. J. Wurtman). α-Methyldopa, an unnatural aromatic amino acid (L. Maître, P. R. Hedwall and P. C. Waldmeier). Synthetic *p*-halogenophenylalanines and protein synthesis in the brain (E. M. Gál). Effects of α-methyltryptophan on tryptophan, 5-hydroxytryptamine and protein metabolism in the brain (T. L. Sourkes). Chairman's closing remarks (R. J. Wurtman). Index of contributors. Subject index.

Trypanosomiasis and Leishmaniasis

with special reference to Chagas' disease

Ciba Foundation Symposium 20

1974. 366 pages.
Dfl. 46.00 (about: US$ 16.70; £ 7.00)
ISBN 90 219 4021 3

Contents:

Introduction (B. A. Newton). Leishmaniasis and trypanosomiasis: the causative organisms compared and contrasted (W. H. R. Lumsden). Epidemiology of African sleeping sickness (J. R. Baker). Epidemiology, modes of transmission and reservoir hosts of Chagas' disease (R. Zeledón). Epidemiology of leishmaniasis: some reflections on causation (R. S. Bray). The African scene: mechanisms of pathogenesis in trypanosomiasis (L. G. Goodwin). Pathogenic mechanisms in Chagas' cardiomyopathy (A. Anselmi and F. Moleiro). Pathogenesis of Chagas' disease (F. Köberle). Cutaneous leishmaniasis: the clinical and immunopathological spectrum in South America (J. E. Convit and M. E. Pinardi). The ultrastructure of pathogenic flagellates (K. Vickerman). Immunity and antigenic variation: clinical observations suggestive of immune phenomena in trypanosomiasis (P. De Raadt). Nutrition and biosynthetic capabilities of flagellates: problems of *in vitro* cultivation and differentiation (W. Trager). Intermediary metabolism of pathogenic flagellates (I. B. R. Bowman). The chemotherapy of trypanosomiasis and leishmaniasis: towards a more rational approach (B. A. Newton). Drug resistance in trypanosomiasis and leishmaniasis (W. Peters). General discussion. Index of contributors. Subject index.

SAUNDERS TITLES FOR 1974

Nering:

ELEMENTARY LINEAR ALGEBRA

The material, in this text, is presented by use of a careful integration of conceptual material with concrete computational methods. Each abstract concept is identified computationally or geometrically, and every abstract argument or proof is realized in a computational process either by example or by description.

By Evar D. Nering, *Arizona State University*

375 pages. Illustrated. February 1974. **£4.70**

Barnes:

INVERTEBRATE ZOOLOGY

Third Edition

This book has been the leading text in its discipline for several years, and this edition is a strong and careful revision. In addition to updating the material, Dr. Barnes has changed his emphasis somewhat, more ecological and behavioural ideas. The results should be presentations that are easier for the students to learn.

By Robert D. Barnes, PhD, *Professor of Biology, Gettysburg College.*

About 775 pages. Ready June 1974. Approx. **£5.75**

Guyton:

FUNCTION OF THE HUMAN BODY

Fourth Edition

A leading text for elementary courses in human physiology, requiring little background of the students and featuring some notably clear writings and illustrations. Among the chapters that have been heavily rewritten are those on genetic control of protein synthesis, transplantation, the role of the renin-angiotensin system in renal hypertension, and the regulation of cardiac output.

By Arthur C. Guyton, MD, *Professor and Chairman, Department of Physiology and Biophysics, University of Mississippi School of Medicine.*

473 pages. 363 illustrations. February 1974. **£4.50**

Brescia et al:

CHEMISTRY: A MODERN INTRODUCTION

This text is designed to provide a background in the fundamentals of chemistry for students of varying chemical training. No previous background in chemistry or mathematics beyond elementary arithmetic is needed to learn from this text. Although written in relatively simple language, subject matter is not slighted and is sufficient to prepare the student for advanced study in chemistry.

There is a STUDENT'S GUIDE by David W. Brooks which has been prepared as an ancillary work to accompany this text.

By Frank Brescia, PhD, *Department of Chemistry, CCNY;* Stanley Mehlman, PhD, *Department of Chemistry, SUNY at Farmingdale;* and Seymour Stambler, *Department of Chemistry, Staten Island Community College.*

About 700 pages. Illustrated. Ready May 1974.

Approx. **£5.90**

Blakemore:

SOLID STATE PHYSICS

Second Edition

This text contains a unified and coherent treatment of the most important phenomena of Solid State Physics. The unifying thread of the book lies in the description of the periodic structure of a crystalline solid and on the effects periodicity has on the motion of electrons and on the allowed spectrum of lattice vibrations.

This text will also be published in a paperback edition. Publication should be simultaneous with the hardback edition.

In publishing the second edition we have taken into consideration requests for S.I. units to be used, therefore in this edition S.I. units are employed throughout.

By John S. Blakemore, PhD, *Florida Atlantic University, Boca Raton.*

About 400 pages. Ready June 1974. Approx. **£6.75**

(Paperback approx. **£3.40**)

matters arising

Solar activity and climatic change

SIR,—Following John Gribbin's article (*Nature*, **246**, 453; 1973), we wish to draw your attention to an unpublished thesis by Dr J. Laszewski (University of Warsaw) which supports Gribbin's suggestions (see also ref. 1). A translation of this thesis is available in the library of The Institution of Civil Engineers.

Laszewski (now professor at the University del Zulia in Maracaibo, Venezuela) has collected long term records of the mean annual discharges of many rivers in Europe, North and South America, Africa and Australia. He demonstrated that the mean annual discharge varies in a cyclic manner which is connected in a complex way with the cycles of sunspots. This is a result of the changes in the atmospheric circulation influenced by the sunspot cycle. The long cycles are divided into shorter cycles, so the story is very complex.

Although none of the records of river discharges examined cover more than about 150 yr and most cover less than 100 yr, one may suspect that the cycle of 200 yr suggested in Gribbin's article is detectable.

Yours faithfully,

T. M. PRUS-CHACINSKI

Refining geoid heights

SIR,—In their recent paper refining the longitude-averaged geoid height with improved values for the zonal harmonics in the geopotential, King-Hele and Cook[1] show their latest version of the height of the meridional geoid section relative to a spheroid of flattening 1/298.25. In this definition an axially symmetric Earth is assumed.

If the distribution of Precambrian exposed and overlaid rocks[2] is expressed as the ratio of their occurrence along a particular line of latitude to the total length of that line (that is longitude 0° to 360°) and plotted against latitude, there seems to be reasonable correlation with geoid height. The actual proportions are plotted in Fig. 1 together with a smoothed curve on twice the scale.

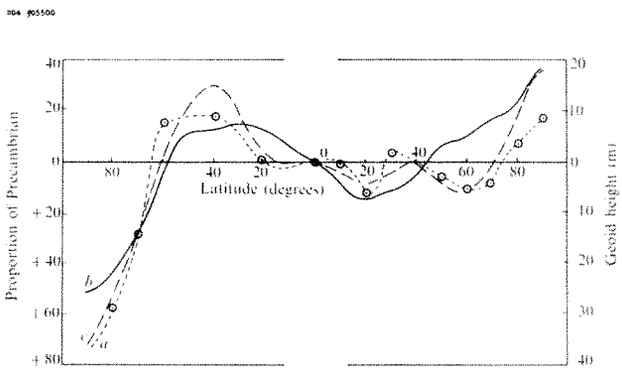

FIG. 1 Comparison of geoid heights given by King-Hele and Cook[1] with proportion of Precambrian stable areas. *a*, Proportion of Precamprian rock; *b*, geoid height, after King-Hele and Cook[1]; *c*, precamprian proportion smoothed on double scale.

A similar correlation exists with longitude for the gravimetric geoid published by Marsh[3] which agrees well with the Smithsonian Standard Earth 1969 (ref. 4). The geoid height at latitude 35°N is plotted against longitude in Fig. 2 and the distribution of Precambrian rocks is shown together with the extent of regions of Tertiary and Hercynian folding, which appear to have some significance, particularly in regions of orogeny such as 35°N, 65°E.

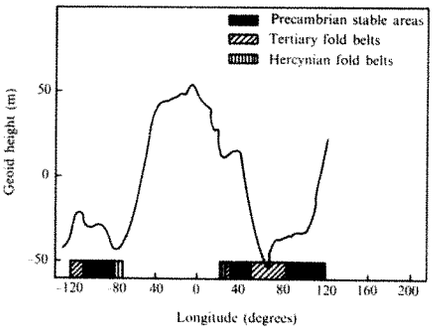

FIG. 2 Detailed gravimetric geoid at latitude 35° N showing correlation with geological formation.

The surprising feature of these effects is that the geoid height seems to be lower than the 1/298.25 spheroid in the stable land areas and higher than it in the oceanic areas. This is the reverse of what would have been expected intuitively.

Yours faithfully,

B. P. DAY

Left and right in Goya's portraits

MCMANUS and Humphrey[1,2] have described biases in the frequency with which more of the right or left sides of faces are shown in paintings. Examination of 1776 portraits by different artists revealed that, overall, 57% showed more of the left side of the sitter's face. Whilst self-portraits tended to show more of the right side of the face (61% of those examined), male portraits tended to show more of the left side of the face (56%) and female portraits showed an even stronger bias towards the left (68%).

In an analysis of 335 portraits by Rembrandt, the same authors found that the frequency with which more of the left face is shown increases progressively across the following categories of sitter: self, male kin, male non-kin, female kin, female non-kin. To explain this it was suggested that the categories represent positions on a dimension 'socially like myself—socially unlike myself' along which Rembrandt placed his sitters. The choice of mainly left or right face was an indication by Rembrandt as to how he perceived his social relationship with the subjects of his portraits.

Table 1 summarises an analysis of 295 portraits by Goya taken from a comprehensive illustrated account of his works[3]. Each portrait was classified simply as

TABLE 1 Relative frequencies with which more of the left face is shown in Goya's portraits.

	Self	Male kin	Female kin	Male non-kin	Female non-kin
No. of portraits examined	14	14	12	185	70
No. showing more of the left face	7	9	4	95	50
%	50.0	64.3	33.3	51.4	71.4

showing either full face, or more of the left or right side. The classification of each sitter's relationship to Goya follows that adopted by McManus and Humphrey. The male kin and female kin categories include members of the Bayeu y Subias and Goicoechea families to whom Goya became related through his marriage and that of his son Javier.

Analysis of the data in Table 1 shows, firstly, that Goya's portraits fit the general pattern discovered by McManus and Humphrey in that a majority (56% overall) show more of the sitter's left face. This result is statistically significant (Binomial Test, $Z = 1.98$, $P = 0.024$, one-tailed). There is also a significant sex difference in that, overall, female portraits are more likely to show the left side of the face ($\chi^2 = 4.4$, $P < 0.05$); this result agrees with the original finding by McManus and Humphrey. Analysis of the data in terms of kin compared with non-kin, however, does not reveal any significant relationship ($\chi^2 < 1.0$). More detailed examination of Goya's portraits makes it seem even more unlikely that perceived social relationships influenced Goya's choice of which side of faces to paint: thus of 15 of Goya's self portraits, one is full face, seven show more left face and seven more right; of the four portraits of Goya's son, two show more left face, two more right; all three portraits of Goya's beloved grandson, Mariano, show more left face.

Whilst Goya's works provide evidence which agrees with McManus and Humphrey's interesting general findings about left and right in portraits, their hypothesis relating choice of side and the relationship between artist and sitter is not supported. This could mean either that the effect occurs only with certain artists, or that certain relationships discovered in Rembrandt's portraits are due to other causes, some of which have already been suggested[4].

Yours faithfully,

I. E. GORDON

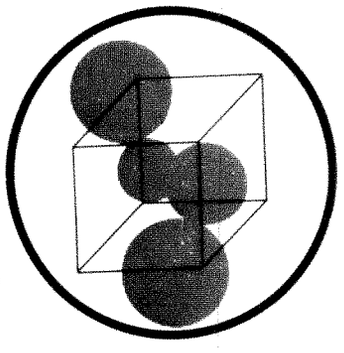
Biological differentiation –a new journal.

Biological research has for too long suffered from restricted experimental attitudes and 'vertical' thinking.

Now Differentiation, an important new publication, provides the opportunity for interdisciplinary communication and increasing fertilization of ideas across the artificial boundaries created by overspecialization. This journal, published bi-monthly, offers up to date information and synthetic views of a problem underlining the whole biological phenomenon – differentiation.

The first five issues contained papers on:
Degree of differentiation in nonproliferating cells of mammary carcinoma. C. V. Wylie, P. K. Nakane and G. B. Pierce.
Polyribosome profiles and polyribosome-associated RNA of Friend leukaemia cells following DMSO-induced differentiation. H. D. Preisler, W. Scher and Charlotte Friend.
Studies on cytology and differentiation in Sciaridae. 5. Electron microscopic studies on the salivary glands of *Bradysia elegans* Morgante (Diptera, Sciaridae). A. B. Da Cunha, R. W. Reiss, C. Pavan, J. J. Biesele, J. S. Morgante and M. C. Garrido.
The principle of sequential dependence in cellular differentiation. P. A. Riley.
Time lapse filming of cellular interactions in organ culture. 2. The behaviour of malignant cells. E. J. Ambrose and Dorothy M. Easty.
Intercellular levels of cyclic nucleotides during cell enlargement and cell division in excised tobacco pith tissues. C. V. Lundeen, H. N. Wood and A. C. Braun.
Pattern formation in *Dictyostelium discoideum*: temporal and spatial distribution of prespore vacuoles. Ursula Muller and R. Hohl.
The enrichment of egg-type RNA in cleavage stage embryos of the sand dollar *Dendraster excentricus*. Shigeki Mizuno, H. R. Whiteley and A. H. Whiteley.
DNA synthesis and the production of antibodies by lymphoid tissues. G. Harris.
Neurite extension by mouse neuroblast: evidence for two modes of induction. P. Furmanski.



The journal aims to cover the following areas of study: embryonic Differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions *in vivo* and *in vitro*, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Contributions for publication are invited by The Editor.

Editor: Dimitri Viza. Faculté de Médecine Pitié-Salpétrière, Laboratoire d'Immunobiologie. 105 Boulevard de l'Hôpital, 75634 Paris Cédex 13, France.

APPOINTMENTS VACANT

UNIVERSITY OF STIRLING
PLANT BIOLOGY
A.R.C. RESEARCH ASSISTANTSHIPS

Applications are invited for research assistantships on the following topics:

1. The role of Phytoalexins in the resistance of the broad bean to fungal infections (with Dr. J. W. Mansfield).
2. Physiological aspects of seed development in peas (with Dr. S. Matthews).

Successful applicants will be expected to register for Ph.D. degrees. Enquiries to Professor H. Meidner, Biology Department, University of Stirling, Stirling FK9 4LA. (1785)

BIOCHEMIST

required to join group studying male reproduction and fertility control. Previous experience in hormone assays of advantage. Knowledge of German not required. Salary range: DM 2,000 to DM 3,000 per month. Apply to: Wr. E. Nieschlag, 2. Medical Clinic of the University, Moorenstrasse 5, 4 Düsseldorf (Germany). (1787)

IMPERIAL COLLEGE
DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT required for S.R.C. sponsored work on computer studies of absorbed fluids. Appointment for 2 years under supervision of Dr. D. Nicholson and Dr. N. G. Parsonage, to begin on September 30, 1974 or as otherwise arranged. Starting salary £1,929 (scale under review) plus £162 London Allowance, with F.S.S.U.

Applications, naming two referees, to Dr. D. Nicholson, Department of Chemistry, Imperial College, London SW7 2AY before June 10, 1974. (1790)

FIELD STUDIES COUNCIL

Required for September 1974. Tutor at the Epping Forest Conservation Centre, Essex. Single geographer to help with junior environmental work as well as more advanced classes. Duties also include sharing interpretive services to the general public. Salary: £1,200 by £75 to £1,350, plus residential benefits. Closing date May 31, 1974. Further details and application forms from The Director, Field Studies Council, Preston Montford, Montford Bridge, Shrewsbury SY4 1HW. (1791)

CHAIRMAN, DIVISION OF TUMOR IMMUNOLOGY ST. JUDE CHILDREN'S RESEARCH HOSPITAL

St. Jude Children's Research Hospital is seeking a distinguished scientist to organise and chair a division of tumor immunology. Applications are invited from persons with demonstrated expertise in basic immunology. Letters of application, with curriculum vitae, should be sent to: Dr. R. G. Webster, Chairman, Search Committee, St. Jude Children's Research Hospital, P.O. Box 318, Memphis, Tenn. 38101. AN EQUAL OPPORTUNITY EMPLOYER/MALE AND FEMALE. (1792)

CSIRO

SOLAR ENERGY STUDIES MELBOURNE VIC

AUSTRALIA

RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

GENERAL : The recently appointed Director of Solar Energy Studies has responsibility for developing policy and plans for research into the use of solar energy within CSIRO. This involves feasibility studies, determination of areas of best potential, analysis and provision of data needed in common by research workers in this field and contact with solar energy research workers in Australia and overseas.

Application for the following position is invited from persons interested in participating in this programme.

DUTIES : To undertake studies of the thermal applications of solar energy and generally to assist in the planning and execution of the Solar Energy Studies programme, including publication of the results of these studies.

QUALIFICATIONS : A Ph.D. degree in Engineering or Science or equivalent qualifications, and demonstrable research ability. Experience in the industrial application of the results of research is required, not necessarily in the solar energy field.

SALARY : The appointment will be within the salary ranges of Senior Research Scientist or Principal Research Scientist : $A12,298—$A17,077 p.a.

TENURE : This position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference No. 428/3 should reach:

The Personnel Officer, Australian Scientific Liaison Office, 64-78, Kingsway, London, WC2B 6BD by the 7th June, 1974.

Applications in U.S.A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C. 20036, U.S.A. (1798)

AUSTRALIA
UNIVERSITY OF NEW SOUTH WALES
WOLLONGONG UNIVERSITY COLLEGE
To become
THE UNIVERSITY OF WOLLONGONG
on January 1, 1975

PROJECT SCIENTIST

Applications are invited from Ph.D.'s with a background in quantum chemistry for the position of Project Scientist in the Department of Chemistry. The successful applicant will be expected to work with Dr. P. G. Burton on a project involving studies of the influence of the environment on the chemical reactivity of molecules in condensed media. New theoretical methods of electronic structure computation will be used and a detailed working experience with large **fortran** programmes will be an advantage. Of particular interest are transition metal systems and the study may impinge on areas of inorganic photochemistry and of functions of metalloproteins.

Appointment in the first instance will be for fourteen months beginning September/October, 1974, with initial salary of A$8,698 (£5,423 approx.).

Further details of the project are obtainable from Dr. Burton and applications should be made to the College Bursar, Wollongong University College, P.O. Box 1144, Wollongong, NSW 2500, Australia, by May 31, 1974.

Applicants should request two referees to write immediately to the College Bursar. (1722)

UNIVERSITY OF READING
UNIVERSITY OF IBADAN
METEOROLOGY

Applications are invited for a new post of temporary (a) Lecturer/(b) Senior Lecturer in Meteorology, established in co-operation with the Inter-University Council for Higher Education Overseas.

Candidates should possess a higher degree in Meteorology and/or have had appropriate research experience in Meteorology. The person appointed will be a full member of the staff of the Department of Geophysics in Reading, in which he will serve on home duties, but he (or at times a substitute from the Department) will be expected to spend four years on the contract period on secondment overseas to the University of Ibadan, Nigeria. The appointment will be for a period of five years terminable by six months' notice on either side.

The British Government may provide supplementation under the British expatriates supplementation scheme at the rate of (a) £950 p.a. for a married appointee or £450 single; (b) £1,150 or £650. Children's education allowances, holiday visit passages and other benefits may also be provided.

Further particulars may be obtained from the Secretary, Overseas Service Unit, University, Whiteknights, Reading RG6 2AH, by whom applications should be received by May 31, 1974. (1729)

THE OPEN UNIVERSITY
BIOLOGY TECHNICIAN (2b)

A vacancy exists for a BIOLOGY TECHNICIAN (GRADE 2B) in the Faculty of Science commencing June 1, 1974 or as soon as possible thereafter. Main duties will include: assistance with course experimental work; the construction and servicing of biology summer school and day school equipment; general maintenance of services and equipment in the biology laboratories.

Applicants should possess O.N.C. or equivalent qualifications. Four to six years experience in laboratories (preferably biological), experience of constructing equipment and knowledge of the use of workshop equipment will also be required.

Salary, based on qualifications and experience will be within the Grade 2B scale: £1,524 to £1,794 per annum.

Further details and application forms are available from the Personnel Manager (TS2), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL. (Tel: Milton Keynes 74066, extn. 3068). Closing date for applications: Friday, May 24, 1974. (1794)

BREWING INDUSTRY RESEARCH FOUNDATION
NUTFIELD, SURREY
CHEMISTS

Two Chemists are required in the Chemistry Section to work on the chemistry of raw materials used in the brewing process.

One appointment will be made at Research Fellow (post doctoral) level for which experience in the chemistry of natural products would be a distinct advantage.

The other appointment will be made at Experimental Officer level and would be suitable for a first degree graduate whose main interest is organic chemistry. Students expecting to graduate this summer are invited to apply.

Present salary range for both appointments £1,849-£2,848 p.a.

Applications, together with the names of two referees and curriculum vitae should be sent to the Administrative Manager, Brewing Industry Research Foundation, Nutfield, Redhill to arrive not later than June 14, 1974. (1718)

THE NORTH OF SCOTLAND COLLEGE OF AGRICULTURE
ABERDEEN
POULTRY ENVIRONMENT SPECIALIST

Applications are invited for a new post in the Poultry Division of the College. Candidates should have an Honours Degree in Biology or a Biological Science together with post-graduate research experience preferably in whole animal biology. Excellent modern facilities for research and development.

Entry according to age and qualifications on scales:

Grade III—£2,328 x 16 increments to £4,061.

Grade IV—£1,584 x 7 increments to £2,148.

Forms of application and further particulars of the post (Reference Number 29/74), obtainable from the Secretary, The North of Scotland College of Agriculture, 581 King Street, Aberdeen AB9 1UD with whom applications should be lodged **not later than May 27, 1974.** (1719)

THE OPEN UNIVERSITY
BIOLOGY TECHNICIAN
(Temporary Post)

An immediate vacancy exists for a BIOLOGY TECHNICIAN (Grade III) with experience of Microbial Genetics, especially sterile techniques. He/she will assist in the preparation of experimental materials, including television and other display work, associated with a Nuffield/Open University Genetics Course. The appointment will be for three years.

Salary, based on qualifications and experience, will be within the Grade III scale: £1,650 to £1,920 per annum.

For details and application forms, please contact The Personnel Manager (BT2), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL. (Tel: Milton Keynes 74066, extension 3068). Closing date for applications: Friday, May 24, 1974. (1788)

Glaxo

Glaxo Laboratories Limited
Technical Officer (Chromatography)
ULVERSTON

Applications are invited for a post as Technical Officer (Chromatography) in the Chemical Process Development Department at Glaxo Laboratories' bulk antibiotics plant, Ulverston, Cumbria. Experience or interest in the field of Chromatography is required to work primarily on the application of High Pressure Liquid Chromatography to problems connected with the manufacture of antibiotics. The successful candidate will form part of a well-established small group already well versed in paper, thin layer and gas chromatographic techniques. He or she will preferably have an HNC or HND in chemistry or be engaged upon such courses.

Every encouragement will be given to those wishing to continue their studies.

The Company offers good conditions of service including bonus, pension and sick-pay schemes and environmental aspects are second to none. The town of Ulverston is situated on the shores of Morecambe Bay and on the southern fringe of the Lake District National Park.

Apply in writing, quoting reference U.526, to The Personnel Officer (JE), Glaxo Laboratories Limited, Ulverston, Cumbria LA12 9DR. (1771)

BEDFORD COLLEGE
(University of London)
RESEARCH ASSISTANT
in
ZOOLOGY

Research Assistant required to work under a three year N.E.R.C. grant on respiratory physiology of annelids subjected to low oxygen tensions. Applicants should have a good Honours degree in Zoology or Biochemistry. The appointment will date from October 1, 1974. Salary £1,500 by 2/£87 to £1,674.

Application forms may be obtained from the Assistant Secretary (Personnel) (N), Bedford College, Regent's Park, London NW1 4NS (Tel. 486 4400 Ext. 312). (1793)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
Department of Physics
OPPORTUNITIES FOR RESEARCH IN OPTICS AND LASERS

Applications are invited for vacancies at Post-Doctoral Research Assistant and Postgraduate (M.Phil. and Ph.D. by thesis, M.Sc. by course) levels. The optics section undertakes research in laser and optical physics (including the interaction of high power laser with matter), coherent optics, optical design and visual optics. The Post Doctoral Research Assistant salary scale is from £1,929 to £3,048 plus £162 London allowance (under review).

The SRC is prepared to offer a limited number of advance course and research studentships. Support for research students and post-doctoral appointments is also available on contracts from government and industrial laboratories. Experienced researchers: students expecting to be awarded a good Honours degree in physics, electrical engineering or electronics: and graduates with relevent industrial experience can obtain further details and application forms from Professor D. J. Bradley, Optics Section, Department of Physics, Imperial College, Prince Consort Road, London SW7 2BZ. (1721)

THE EDINBURGH SCHOOL OF AGRICULTURE
RESEARCH ASSISTANT

Applications are invited for a research assistantship for work on animal behaviour under the direction of Dr. D. G. M. Wood-Gush. The work will be exclusively with pigs.

Salary: £1,500.

Further particulars and application form from the Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (1786)

Avian Research

Pedigree Petfoods seeks a man or woman to take over and develop the Company's avian research programme in the broad areas of nutrition, reproductive endocrinology and toxicology. The person appointed will report direct to the Head of our Animal Studies Centre which is recognised as one of the foremost Small Animal Nutrition Centres in Europe, and will join a group of other scientists engaged in behavioural and nutritional research, establishing him/herself as the Company authority on avian matters.

Applicants should have a good primary degree in a biological subject with at least 2 years' relevant post graduate research, not necessarily in the avian field. Some practical experience in avian management would be ideal.

Starting salary will be at least £3,700 on a scale rising to £4,700. In addition we offer non-contributory pension and life assurance and generous re-location allowances. Housing prices are reasonable here in comparison with the South East and the Animal Centre is located in pleasant countryside 5 miles from our plant at Melton Mowbray yet only 35 minutes' drive from Leicester and Nottingham.

If you would like more information about this position and an application form, please telephone or write to: Elizabeth Hague, Management Recruitment Officer, Pedigree Petfoods Limited, Melton Mowbray, Leicestershire. Tel: Melton Mowbray 4141.

(1774)

National Institute for Medical Research
Mill Hill – London

GRADUATE Biologist or experienced technician required by the Division of Cytopathology to assist in work on the electron microscopy of viruses and cell membranes with particular emphasis on cryo-techniques using freeze etching equipment. Salary on scale £1533—£2199 p.a. Non-graduates with suitable experience will also be considered for this post on salary scales related to their qualifications. Please quote ref: JTO/Cyto.

GRADUATE Biochemist required to assist in research on membrane biochemistry. Biochemical experience will be an advantage. Salary on scale £1533—£2199 p.a. Please quote ref: JTO/LBTCS.

TECHNICIAN/JUNIOR TECHNICIAN, preferably with microbiological or biochemical experience, required to assist in work on mechanisms of resistance to Bacterial infections in the Laboratory of Bacterial Infectivity. Candidates with HNC or equivalent will be considered for appointment to the Technician grade, £1566 p.a.—£2418 p.a. Those who are currently following an HNC course or who have ONC will be appointed as Junior Technician, £946 (at 17)—£1521 p.a. Please quote ref: Tech/LBI.

Applicants for the above should contact P. A. Collingridge, N.I.M.R. The Ridgeway, Mill Hill, NW7 1AA, Tel: 959-3666. (1752)

The University of Leeds
DEPARTMENT OF PHYSIOLOGY
CARDIOVASCULAR UNIT

Applications are invited for a post of RESEARCH ASSISTANT. The post is financed by the Medical Research Council and previous training in neurophysiology is necessary. The appointment will be made for one year in the first instance and the salary will be on a scale rising to £2,500.

The successful candidate would work in the basic laboratories of the Unit which are fully equipped to study central nervous and reflex control of the cardiovascular system. The Unit operates its own computer facility. The problems on which the sucecssful applicant will be expected to work are within the field of central projections of cardiovascular afferent fibres to the brainstem. Informal enquiries may be made to the Cardiovascular Unit.

Forms of application and further particulars from the Registrar, The University, Leeds LS2 9JT (please quote 43/13/10). Closing date May 31, 1974. (1763)

ST. THOMAS'S HOSPITAL
MEDICAL SCHOOL
DEPARTMENT OF GYNAECOLOGY

Applications are invited for a Research Assistantship in Biochemistry in this Department. The successful candidate will join a group working on problems of oestrogen and gonadotrophin interaction and metabolism. Previous endocrine or radioimmunoassay experience is not essential but would be helpful. Starting salary up to £1,900 according to qualifications. Applications with full details and names of two referees and enquiries to: Dr. M. G. Brush, St. Thomas's Hospital Medical School, London SE1 7EH. (1736)

• UNIVERSITY OF BATH

Applications are invited for a

LECTURESHIP IN GENETICS

in the School of Biological Sciences. Persons interested in any aspect of genetics will be considered. Lecturer salary scale £1,929 to £4,548. Further particulars and application forms obtainable from Registrar (S), The University, Bath BA2 7AY, quoting ref. 74/65. Closing date for receipt of applications May 31, 1974. (1737)

INSTITUTE OF TERRESTRIAL ECOLOGY, GRANGE-OVER-SANDS, LANCASHIRE
ANALYTICAL CHEMIST

An analytical chemist (Scientific Officer) is required by the Chemical Section at Merlewood Research Station, Grange-over-Sands, Lancashire.

The work is concerned with the analysis of plant materials, soils and waters for a wide range of inorganic and organic constituents in connection with ecological and pollution studies.

Qualifications: Normally under age 27 with a pass degree, HNC, HND or equivalent in an appropriate subject. Previous laboratory experience with instrumental techniques would be an advantage.

Salary: £1,435 to £2,329. Starting salary may be above the minimum.

Superannuation arrangements.

Application forms and further particulars available from Institute of Terrestrial Ecology, Alhambra House, 27/33 Charing Cross Road, London WC2H 0AX.

Closing date: May 31, 1974. (1733)

UNIVERSITY OF ABERDEEN
RESEARCH ASSISTANTSHIPS IN BIOCHEMISTRY

Applications are invited for TWO POSTS—(i) to work with Dr. C. K. Pearson on the initiation and control of DNA synthesis in mammalian cells in tissue culture and (ii) to investigate the organisation of reiterated base sequences in eucaryotic DNA, under the supervsion of Dr. N. Hardman. Applicants should possess, or be in process of obtaining, an honours degree in Biochemistry or an allied subject. Both posts are for three years and suitably qualified applicants may register for a higher degree. Salary in range £1,479 to £1,659 (under review).

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by May 25, 1974. (1734)

UNIVERSITY OF QUEENSLAND
AUSTRALIA
LECTURER IN MATHEMATICAL STATISTICS
DEPARTMENT OF MATHEMATICS

An applicant should possess a higher degree and have research interests in any branch of statistics including probability and stochastic processes.

Salary: Within the range of $A8,698 to $A11,982 per annum.

Other Benefits: Lecturers Superannuation similar to F.S.S.U., housing assistance, study leave, and travelling and removal expenses.

Additional information and application forms are obtainable from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close in London and in Brisbane on **May 27, 1974.** (1725)

AUSTRALIA

PUBLIC SERVICE OF VICTORIA
MINISTRY FOR CONSERVATION
FISHERIES AND WILDLIFE DIVISION
RESEARCH OFFICER
(THREE POSITIONS)

Yearly Salary: (a) $A6,229 minimum; $A8,981 maximum.
(b) $A9,151 minimum; $A10,674 maximum.

Note: Generally appointment will be within the salary range (a) according to qualifications and experience but applicants possessing special qualifications or extensive experience may be considered for appointment to salary range (b).

Position No. 1. Ref. No. (I/01)

Duties: Under the direction of the Officer in Charge, Freshwater Fisheries, to undertake a research programme based on the Seven Creeks system and the fish population therein. To carry out nutrition trials on both native and introduced fish species at the Snob's Creek Freshwater Fisheries Research Station and Hatchery. Other duties as directed.

Qualifications: An approved degree in Science or Agricultural Science or an equivalent qualification; research experience in an appropriate field is desirable. Experience in fisheries research and/or animal nutrition an advantage.

Note 1. The successful applicant will be required to occupy a residence within the Hatchery grounds. A rental of approximately 9% of salary a year will be charged.

Note 2. To reside at Snob's Creek Fish Hatchery. The successful applicant will be stationed at the Arthur Rylah Environmental Research Institute, Heidelberg, for approximately six months as from the commencement of duty.

Position No. 2. Ref. No. (I/02)

Duties: Under the direction of the Officer in Charge, Freshwater Fisheries, to undertake research into the freshwater eel stocks and to develop a policy for the commercial exploitation of these fish. To undertake other research programmes into the biology of selected freshwater fish inhabiting coastal streams. Other duties as directed.

Qualifications: An approved degree in Science or Agricultural Science or an equivalent qualification; research experience in an appropriate field is desirable. Experience in eel fisheries including intensive culture, and/or population dynamics of fish stocks an advantage.

Position No. 3. Ref. No. (I/03)

Duties: Under the direction of the Officer in Charge, Freshwater Fisheries to undertake research studies into the basic biology of selected freshwater fish species. Other duties as directed.

Qualifications: An Approved Degree in Science or Agricultural Science or an equivalent qualification; research experience in an appropriate field is desirable; specialist training or experience in physiology an advantage.

Note 1. The successful applicants for position Nos. 2 and 3 will be stationed at 123 Brown Street, Heidelberg.

Note 2. Separate applications must be submitted for these positions.

Applications quoting appropriate reference number should be addressed to the Secretary, Public Service Board of Victoria, State Public Offices, No. 1 Treasury Place, Melbourne, 3002, Australia, by not later than 9.30 a.m. on Wednesday, 5th June, 1974, together with statements of experience and qualifications and date and place of birth. (1743)

THE OPEN UNIVERSITY
RESEARCH ASSISTANT IN BIOLOGY

Applications are invited for a **Research Assistantship in Biology**, tenable from June 1, 1974 or as soon as possible thereafter, to work with Dr. Gary Dutton of the Brain Reesarch Group on **glycoprotein metabolism in the brain.** Applicants should possess a 1st or good 2nd class honours degree in biochemistry or have equivalent neurochemical experience. The appointment will be for one year initially with the possibility of further renewal.

Salary scale: £1,323 to £2,058 per annum with F.S.S.U. benefits.

Further details are available from The Personnel Manager (RB2), The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 6AL. (Tel: Milton Keynes 74066 extension 3068). Closing date for applications: **Friday, May 24, 1974.** (1758)

CENTRAL PUBLIC HEALTH LABORATORY

TECHNICIAN

required by the Salmonella and Shigella Reference Laboratory. Suitable qualifications would be a relevant scientific degree; A.I.M.L.T. or H.N.C. in Medical Laboratory Sciences. This is the National Salmonella and Shigella Centre for Great Britain and the Commonwealth and offers training in the most advanced methods of Salmonella and Shigella identification.

Written applications with full details of age, experience and qualifications to the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (1730)

A YOUNG SCIENCE GRADUATE

with a good honours degree is needed for work on Hospital infection. Laboratory and field studies are nivolved, including the development of tracer techniques using fluorescent and other particles. The problems involved are largely physical so that a basic training in the physical sciences may be the most appropriate, but a wide scientific outlook coupled with some mechanical aptitude and ability is more important than the precise course. F.S.S.U. provision and salary according to age, qualifications and experience on M.R.C. scale rising to £3,378 plus London Allowance.

Applications to Dr. O. M. Lidwell, Cross Infection Reference Laboratory, Public Health Laboratory, Colindale Avenue, London NW9 5HT. (1764)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF FORESTRY AND NATURAL RESOURCES

A.R.C. RESEARCH ASSOCIATE

Applications are invited from candidates with three or more years research experience for the position of Research Associate in the Department of Forestry and Natural Resources, University of Edinburgh, to work on the effects of wind on the performance of forage grass species. The project is supported by a three-year grant from the Agricultural Research Council. The appointee will work both in the field and with a controlled environment wind tunnel, being concerned with plant water relations and photosynthesis. Suitably relevant research experience and ability to work in a team within a broadly based Department are essential.

Salary will be according to age and qualifications on the following scale: £1,929 by £129 to £2,058 by £165 to £2,223 per annum (under review), with F.S.S.U. benefits.

Further particulars on request to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL, to whom applications should be sent not later than May 30, 1974, giing full details of qualifications and experience together with the names of two academic referees. Please quote reference 5016. (1760)

Physiological Measurement Technician

£1332-£1803

To assist consultant anaesthetists and senior registrars at St George's Hospital, Tooting, London S.W.17 with research projects in General and Dental Anaesthesia, including pulmonary function tests, blood gas and gas analysis, circulatory and respiratory monitoring. Duties include preparation, setting up, calibration and checking equipment; preliminary calculations and checking results; preparation of charts and diagrams. Experience of blood gas measurement desirable, but not essential.

Facilities include Canteen, active Sports and Social Club, and Staff Health Service. The appointment will be for the duration of the research projects, i.e. until the end of January 1975. Further details and application forms from Personnel Office, The Royal Dental Hospital, 32 Leicester Square, London WC2H 7LJ. Tele: 01-930 8831 extension 11. (1720)

FOOD SCIENTIST

DEPARTMENT OF AGRICULTURE AND FISHERIES

The person appointed will advise the Department on all aspects of compositional food standards. The appointment will be made in the grade of Agricultural Inspector.

Essential: (i) 1st or 2nd class Honours University Degree in **Food Science, Dairy Science, Chemistry, Biochemistry** or **Microbiology** or an equivalent qualification.

(ii) At least five years' post-graduate experience including adequate experience of processing techniques and quality control in the food industry or in food analysis or research.

Salary: **£3,352–£4,742** (man)
£2,844–£4,221 (woman)
Entry up to maximum possible.

Age Limit: 45 years.

CLOSING DATE: 23rd MAY 1974

Application forms, etc. from Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin 1. (1738)

ROYAL HOLLOWAY COLLEGE
(University of London)
Egham Hill, Egham, Surrey
CHEMISTRY DEPARTMENT

RESEARCH ASSISTANTSHIPS IN COMPUTER SIMULATION OF LIQUIDS

Applications are invited for two Postdoctoral Assistantships for work on the computer simulation of liquids at molecular level in a group led by Professor K. Singer. A background in statistical mechanics is desirable.

The appointments are for two years at a salary in the range £1,929 to £2,223 plus F.S.S.U.

Further details may be obtained from the Personnel Officer (N), to whom applications together with curriculum vitae and the names and addresses of 2 referees should be sent as soon as possible. (1795)

WESTFIELD COLLEGE
(University of London)
DEPARTMENT OF BOTANY AND BIOCHEMISTRY

DEMONSTRATOR

Applications are invited for this newly created post in the department, tenable from September 1, 1974. Candidates should have a good degree in Plant Sciences or Microbiology preferably with an interest in experimental, physiological or biochemical education. The main duties of the post are the organisation and supervision of undergraduate laboratory classes. The appointment will be for a period of three years, subject to annual renewal. The salary is within the range £1,404 to £2,388 plus London Allowance. Further particulars from the Personnel Officer (N), Westfield College, Kidderpore Avenue, Hampstead, London, NW3 7ST with whom applications close on June 1, 1974. (1797)

UNIVERSITY OF BIRMINGHAM
CHARLES HAYWARD CHAIR OF GERIATRIC MEDICINE

Applications are invited for the newly established Charles Hayward Chair of Geriatric Medicine in the Department of Medicine. Appointment from a date to be arranged.

Salary in the clinical professorial range, maximum £7,599.

Further particulars obtainable from the Registrar, University of Birmingham P.O. Box 363, Birmingham B15 2TT, to whom applications (12 copies: one from overseas applicants) naming 3 referees, should be sent by June 17, 1974. (1741)

UNIVERSITY OF AUCKLAND
NEW ZEALAND

PROFESSOR AND HEAD OF THE DEPARTMENT OF ELECTRICAL ENGINEERING

Applications are invited for the above-mentioned Chair; Professor A. G. Bogle assumes a Personal Chair on his election as Dean of the School of Engineering for a further term. The main fields of research being pursued at present are: antennas, surface wave propagation, radio astronomy, semiconductor device modelling, system simulation and control, active networks and medical intrumentation.

Professorial salaries are at present established within the range NZ$13,863 to $17,645 per annum having regard to the qualifications of the candidate concerned.

Superannuation is on FSSU basis. Fares and other removal expenses are allowed within specified limits.

Further particulars and application procedure available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on **May 31, 1974.** (1757)

ICI in Australia

Research Leader

Animal Health

We are seeking a highly qualified and experienced scientist to head an Animal Health Research Team in our Associate Company in Australia. The laboratory is attractively situated near Melbourne.

ICI Australia has made a number of major contributions to veterinary science and is planning a substantial expansion in its animal health research effort.

The position: The Research Leader will be responsible to the Research Manager of ICI Australia Ltd. for the planning and direction of the Company's research in the area of Animal Health, particularly the development of agents for the control of animal parasites and for the regulation of animal metabolism, on a world-wide basis. The staff include chemists, biologists and biochemists and the final team will number about 40 research workers.

The Research Leader's first duty will be to build up this team with the assistance of colleagues and Personnel Department staff and he should be willing to undertake the difficult task of selecting the right people. Liaison with the parent company's extensive research organisation in the UK will be an important function and some overseas travel will be required.

Qualifications: The applicant should be a graduate in veterinary or biological science. Extensive research experience is essential and he should have proven ability in research planning and organisation. Industrial research experience would be desirable but not essential.

Age: Age is not critical. Qualifications, experience and suitability for the position are the major criteria.

Salary and Conditions: This is a senior staff position and an attractive salary will be offered. For an outstanding candidate a salary at Reader to Professorial level will be negotiated. Benefits include a contributory Staff Pension Fund, liberal recreational leave and a non-contributory medical benefits scheme. Removal and travel expenses will be met by the Company and housing assistance will be provided.

Applications in writing to:
J. Leak, Assistant Personnel Manager, ICI Ltd., Pharmaceuticals Division, Alderley House, Alderley Park, Macclesfield, Cheshire.

(1749)

THE MOTOR INDUSTRY RESEARCH ASSOCIATION

A research engineer is required in the Vehicle Safety Section for interesting and varied work connected with the role of vehicles in road accidents, including research on impact test methods, statistical aspects of road accidents and ergonomics. The successful applicant will probably have a good honours degree in mechanical engineering (or related subjects) and up to seven years' experience since leaving university. A knowledge of statistical methods is desirable.

Applications, in writing, to the Personnel Manager, The Motor Industry Research Association, Nuneaton, Warwicks, giving details of experience, qualifications and current salary and quoting MAM/JAS. (1775)

UNIVERSITY OF OTAGO

DUNEDIN, NEW ZEALAND

LECTURER OR SENIOR LECTURER IN CLINICAL BIOCHEMISTRY

Applications are invited from medical or science graduates for the position of Lecturer or Senior Lecturer in Clinical Biochemistry.

Salary, according to qualifications and experience, within the following scales:

Science Graduate: Lecturer NZ$6,753 to $8,568 per annum; Senior Lecturer NZ$8,718 to $11,139 with a bar at $10,232 per annum.

Medical Graduate: Lecturer NZ$9,172 to $13,107 with a bar at $10,836 per annum; Senior Lecturer NZ$13,485 to $15,528 per annum.

Salary scales are subject to both triennial review and cost-of-living adjustments.

Further particulars are available from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close in New Zealand and London on **June 30, 1974.** (1756)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF GENETICS

Applications are invited for a **RESEARCH ASSOCIATESHIP** to work on biometrical genetics and plant breeding.

Salary scale (under review: £1,569 to £2,223 (exceptionally £2,718) plus F.S.S.U.

Further particulars from the Assistant Registrar (S), P.O. Box 363, Birmingham B15 2TT to whom applications (3 copies) naming 3 referees by June 3, 1974. Please quote reference NN4. (1772)

AGRICULTURAL RESEARCH COUNCIL POULTRY RESEARCH CENTRE

Applications are invited for a post within the **SCIENTIFIC/HIGHER SCIENTIFIC OFFICER GRADES** in the Ethology Section of the Poultry Research Centre, for work on reproductive behaviour. The project involves a certain amount of surgical work and the person appointed should be prepared to supervise technical staff.

Candidates should have a pass degree or H.N.C. in an appropriate biological subject, but specialisation in Ethology is not a necessity.

Salary within the scales £1,435 to £2,329 or £2,221 to £2,854 per annum, with placement according to qualifications and experience. A minimum of five years' post-qualifying experience is required for appointment in the higher grade. The post is superannuable with a non-pensionable allowance to offset contributions.

Application forms, which may be obtained from the Secretary, Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh EH9 3JS, should be completed and returned to him not later than May 21, 1974. (1680)

Brewing Industry Research Foundation

NUTFIELD, SURREY

BIOCHEMISTS

Two Biochemists are required for:

(a) Work on the purification and investigation of enzymes active in barley germination; and

(b) for biochemical studies of β-glucans and pentosans.

Appointments will be made as Research Fellows (post doctoral) on the salary range £1,849 to £2,848 p.a. or, for candidates with suitable post doctoral experience, as Scientists on the salary range £2,149 to £3,247 p.a.

Research Fellow appointments are for up to 3 years. Superannuation under F.S.S.U.

Detailed applications should be sent to the Administrative Manager, Brewing Industry Research Foundation, Nutfield, Redhill, Surrey, to arrive not later than May 31, 1974. (1770)

UNIVERSITY OF NEW BRUNSWICK, FREDERICTON, NEW BRUNSWICK, CANADA

Applications are invited for the following positions:

1. Assistant Professor with Ph.D. in Microbiology to teach undergraduate courses in Microbial Infection and Immunity (two-term course) and Applied Microbiology (one-term course). This position is renewable.
2. Assistant Professor with Ph.D. in Zoology to teach an undergraduate course in Experimental and Laboratory Techniques and assist in some other area of the candidate's own speciality. This position is renewable.
3. Assistant Professor with Ph.D. in Genetics to teach a one-term undergraduate course in Introductory Genetics and a one-term course in Cytogenetics. This position is for one year only, replacing a faculty member on sabbatical leave.
4. Assistant Professor with Ph.D. in Animal Physiology to teach a two-term undergraduate course in Comparative Animal Physiology and a one-term undergraduate course in Endocrinology. This position is for one year only, replacing a faculty member on sabbatical leave.
5. Assistant Professor with Ph.D. in Plant Pathology to assist in courses dealing with plant pathogens and to assist in General Biology (Botany). This position is for two years only, replacing a faculty member on leave of absence.
6. Three Instructors to assume major responsibility for laboratory instruction in one of the following areas: (i) General Biology; (ii) General Microbiology; (iii) Experimental and Laboratory Techniques.

Salaries for the above positions will be commensurate with qualifications and experience but appointments will probably be made at, or near, the floor of the ranks advertised: Assistant Professor —$12,500 per annum; Instructors—$8,000 per annum. Applications should be received by June 30, 1974; Appointments effective September 1, 1974 or earlier if possible.

Applications, including curriculum vitae and names of three referees should be sent to: Dr. M. D. B. Burt, Chairman, Department of Biology, University of New Brunswick, Fredericton, New Brunswick, Canada. (1768)

UNIVERSITY OF BIRMINGHAM BRITISH HEART FOUNDATION CHAIR OF CARDIOLOGY

Applications are invited for the British Heart Foundation Chair of Cardiology in the Department of Medicine. Appointment from a date to be arranged.

Salary in the clinical professorial range, maximum £7,599.

Further particulars obtainable from the Registrar, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (12 copies: one from overseas applicants) naming 3 referees, should be sent by June 17, 1974. (1742)

UNIVERSITY OF SOUTHAMPTON

FACULTY OF MEDICINE

LECTURESHIP IN HUMAN MORPHOLOGY

Applications are invited from biological graduates, preferably with a Ph.D., or from medical graduates for a teaching and research appointment in Human Morphology. Previous teaching experience is not essential; good research facilities are available in a variety of fields and experience in electron microscopy would be an advantage. Salary scale £1,929 to £4,548 per annum (by 16 increments) subject to review. Initial salary will depend upon qualifications and experience. Enquiries should be directed to Professor D. Bulmer or Professor D. Mayor, Medical and Biological Sciences Building, Bassett Crescent East, Southampton, from whom further particulars may also be obtained.

Applications should be addressed to the Deputy Secretary (Ext. 2804), The University, Southampton SO9 4NH (7 copies from applicants resident in U.K. and one from others) not later than May 31, 1974. Ref. Na. (1637)

GUY'S HOSPITAL MEDICAL SCHOOL

Paediatric Research Unit

Applications are invited for first or second year postgraduate research assistant to assist with biochemical research on human biochemical genetic disorders.

Applications should be sent to the Administrative Secretary, Paediatric Research Unit, Guy's Hospital Medical School, London Bridge, SE1 9RT. (1744)

SOUTH AFRICAN SUGAR ASSOCIATION EXPERIMENT STATION
Mount Edgecombe, Natal
Republic of South Africa

AGRICULTURAL ADVISORY CHEMIST

Applications are invited for the permanent post of Agricultural Advisory Chemist at the South African Sugar Association Experiment Station at Mount Edgecombe, Natal, Republic of South Africa. Applicants should have at least a B.Sc. degree with Chemistry as a major subject and some agricultural training. Post-graduate experience in soil and plant analysis will be a particular recommendation. The successful candidate will be required to supervise a large chemical services laboratory, and to prepare fertilizer recommendations based on soil and leaf analyses for sugarcane growers. In addition the Advisory Chemist will be expected to study methods of assessing crop nutrient requirements, and to participate in various co-ordinated research projects.

The commencing salary will be dependent upon qualifications and experience, and would be classified in one of the following grades:—

Grade 4: R422—626/month.

Grade 5: R496—755/month.

Application forms, a list of benefits (which include a 10% annual bonus) and conditions of service are obtainable from:

South African Sugar Association,
Fountain House,
125-135 Fenchurch Street,
London EC3M 5EH,
England.

Completed forms, together with curriculum vitae, should be air-mailed directly to:

The Director,
S.A.S.A. Experiment Station,
P.O. Mount Edgecombe, 4300,
Natal,
Republic of South Africa. (1717)

THE WELSH NATIONAL SCHOOL OF MEDICINE
(University of Wales)
DEPARTMENT OF PATHOLOGY

Applications are invited for a

RESEARCH ASSISTANT

for a period of two years, to join a team supported by the M.R.C. Salary £1,278 to £1,980. The appointment entails research on lymphocyte function in a variety of diseases, notably Sarcoidosis. Excellent facilities available in this new teaching centre.

Application forms available from the Registrar, The Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN to whom they should be returned within two weeks of the appearance of this advertisement. (1745)

THE EDINBURGH SCHOOL OF AGRICULTURE
POST-DOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a research assistantship in the Department of Agricultural Biochemistry for work on embryo development in higher plants. Candidates should be qualified in biochemistry or a related discipline.

The appointment, financed by the A.R.C. (salary scale £2,221 to £2,413, with F.S.S.U. benefits), is tenable for three years from October 1, 1974, and will be associated with a small group working on seed development and maturation.

Further details and application form from the Secretary, Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG (1683).

Glaxo

Clinical Trials Officer

An opportunity has arisen for a male or female pharmacist, or graduate in biological science, to join the clinical trial section of the Medical Department. Candidates, aged 24-30 years, must have a pleasant personality and be interested in clinical pharmacology and therapeutics. They will be expected to show initiative and enthusiasm and to aid this, the post offers a stimulating and varied environment as a member of a team involved in the evaluation of new and existing drugs in human disease. It is essential that they can communicate confidently with members of the medical profession, because to initiate and co-ordinate clinical trials, discussions are held with physicians and academic research workers. The successful applicant will, therefore, be playing a role in the battle against morbidity if not mortality. Some travel within the UK will be involved.

The Company operates excellent conditions of employment, including pension and bonus schemes. Please write giving brief details and quoting reference U.776 to the Personnel Officer (JSP), Glaxo Laboratories Limited, Greenford, Middlesex. Telephone: 01-422 3434. (1771)

Pathologist

Shell Research Limited, Sittingbourne, Kent, have a vacancy in the Pathology Division of their Tunstall Toxicological Laboratory for a medical or veterinary graduate. You will be a member of a multidisciplinary team of scientists involved with the investigations of the toxicology of chemicals. You should have a strong interest or experience in experimental pathology. Should you have post graduate experience in pathology this would be an advantage but is not considered to be an essential requirement. The level of appointment will depend on background and experience and the salary offered will be competitive. Please write or telephone for an application form to Shell Research Limited, Recruitment Division (N), PNEL/34, Shell Centre, London SE1 7NA 01-934 2948.

THE UNIVERSITY OF ASTON IN BIRMINGHAM
DEPARTMENT OF PHARMACY

Applications are invited from good honours graduates with a special interest in Physiology and/or Pharmacology for the post of RESEARCH ASSISTANT to work with the Professor of Pharmacology. The post which will be for a period of three years is supported by a Medical Research Council grant to Professor C. B. Ferry and will be subject to M.R.C. regulations.

The project is concerned with the pharmacology of normal and disordered mamalian neuromuscular transmission.

Salary will be within the range £1,206 to £1,869 per annum. Preliminary enquiries may be made to Professor C. B. Ferry. Requests for application forms (which should be returned within 14 days of the appearance of this advertisement) should be sent, preferably on a postcard, quoting Ref. No. 971/ to: Staff Officer, University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET. (1784)

UNIVERSITY OF BRISTOL
SCHOOL OF CHEMISTRY
POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a S.R.C. Postdoctoral Research Assistantship to work on the calculation of potential energy surfaces of electronically excited molecules in collaboration with Professor R. N. Dixon and Dr. G. G. Balint-Kurti. A background in the theory of electronic molecular structure or computing experience will be an advantage.

The appointment which is for one year in the first instance, with a possible extension to two years, is available from October, 1974. Salary range up to £2,247 p.a.

Applications with curiculum vitae and names of two referees to Professor R. N. Dixon, School of Chemistry, Bristol University, Bristol BS8 1TS by June 15, 1974. (1782)

McGILL UNIVERSITY
MONTREAL, QUEBEC, CANADA

Applications are invited for a two year appointment at the Assistant or Associate Professor level for a biologist-physiologist with strong BIO-MATHEMATICAL interests in the Department of PHYSIOLOGY starting September 1, 1974. The department hopes to be able to extend the appointment. Responsibilities include teaching undergraduate and graduate level Science courses. Send applications with curriculum vitae and names of 3 references to:

Ms. Maria Olejar
Dept. of Physiology
3655 Drummond Street
McGill University
Montreal, Quebec, H3G 1Y6, Canada (1779)

LABORATORY TECHNICIAN

required, lady preferred, for Merchants in W.1 area. Adequately equipped laboratory. Duties include analyses of routine samples of commodities, and future research after familiarisation. Ability to write reports and work on own initiative essential. Salary £1,500 neg. Phone 01-636 7525 ex 64. (1802)

UNIVERSITY OF LONDON
CHAIR OF DERMATOLOGY AT INSTITUTE OF DERMATOLOGY

The Senate invite applications for the above Chair. Salary within the range £6,480 to £7,599 a year. Applications (10 copies) should be received not later than June 7, 1974, by the Academic Registrar (N), University of London, Senate House, London WC1E 7HU, from whom further particulars may be obtained. (1776)

UNIVERSITY OF SOUTHAMPTON
FACULTY OF MEDICINE
PHARMACOLOGY—TEMPORARY LECTURESHIPS

Applicatioins are requested from registered medical practitioners or from science graduates with appropriate qualifications for two Temporary Lectureships in Pharmacology on a full- or part-time basis for the academic year 1974/75. Experience in teaching medical students an advantage. Salary within range £3,588 to £5,091 (clinical) or £1,929 to £4,548 (non-clinical). Superannuation.

Further particulars may be obtained from the Deputy Secretary, The University, Southampton SO9 5NH, to whom applications (seven copies from U.K. applicants and one from others) should be sent not later than May 24, 1974. (1657)

UNIVERSITY OF SOUTHAMPTON
FACULTY OF MEDICINE

Applications are invited from registered medical practitioners or from science graduates with appropriate qualifications for two TEMPORARY LECTURESHIPS IN PHARMACOLOGY on a full- or part-time basis for the Academic Year 1974/75. WELSH NATIONAL SCHOOL OF MEDICINE
(UNIVERSITY OF WALES)
TENOVUS SCHOLARSHIP

Applications are invited from candidates who are about to qualify with a degree of a recognised University for a Tenovus Scholarship tenable at Velindre Hospital. Value: £750, £800, £850 for three years.

Applications to the Registrar, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN. (1783)

UNIVERSITY OF DUNDEE
DEPARTMENT OF THARMACOLOGY AND THERAPEUTICS
RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant available from October 1, 1974 and tenable for three years. The successful applicant may register for a Ph.D. degree and will work under the supervision of Dr. D. S. Hewick on a project relating to the role of nitroreduction as a route of drug metabolism. The net salary will be equivalent to the stipend awarded for an M.R.C. Scholarship for training in research methods.

Candidates should have, or expect to obtain this year, a first or upper second class honours degree or equivalent in pharmacy, pharmacology, biochemistry or related subject.

Applications, quoting Ref. Est/30/74 and naming two referees, should be sent to The Secretary, The University, Dundee DD1 4HN by May 31, 1974. (1781)

BIO-RESEARCH LABORATORIES LTD.
CANADA

Applications are invited from qualified Veterinary Pathologists interested in joining the Department of Toxicology in the capacity of Staff Pathologist. Responsibilities will include technical supervision of Autopsy Room and Histology Laboratory personnel and activities. Principally, however, the successful candidate will be responsible for the evaluation of histological specimen material arising out of toxicological research in a variety of laboratory animal species and for the preparation of reports appropriate to the research in question. Salary will be commensurate with qualifications and experience.

Bio-Research Laboratories Ltd. is a Canadian research company operating in the life sciences field. Applications, curricula vitarum and requests for further details may be directed to Dr. C. I. Chappel, Director, Bio-Research Laboratories Ltd., 265 Hymus Blvd, Pointe Claire, Quebec, Canada H9R 1G6. (1799)

UNIVERSITY OF LIVERPOOL
APPLIED ECOLOGIST

Applications are invited for the post of Environmental Advisory Officer in the Environmental rehabilitation Unit of the Department of Botany, providing ecological advice to local authorities and industry. Applicants should possess a good honours degree and postgraduate experience in plant ecology, soil science or agronomy. They should have interest, and preferably experience, in the application of ecological principles to solving practical problems of the environment. Salary £1,959 to £2,178 per annum according to qualifications and experience. Applications should be received not later than June 1, 1974 by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX from whom further particulars may be obtained. Quote ref. RV/N/276007. (1800)

UNIVERSITY COLLEGE LONDON

Applications are invited for the following positions:

1. **RESEARCH BIOCHEMIST** with postdoctoral or equivalent experience.
2. **RESEARCH STUDENTS**, preferably biochemists, one a C.A.S.E. award.
3. **RESEARCH TECHNICIAN** (Grade 3).

The successful applicants will join the interdisciplinary Enzyme Technology Group which has recently been awarded £90,000 by the Science Research Council for a three-year programme on the Technology of Lipophilic Enzymes. The fundamental biochemical aspects of this project will be particularly challenging.

Applications should be made to the Secretary (N), Enzyme Technology Group, Department of Chemical Engineering, Torrington Place, London WC1E 7JE. (1806)

QUEEN MARY COLLEGE
(University of London)
Mile End Road, E1 4NS
POLYMER RESEARCH: EXPERIMENTAL OFFICER

An Experimental Officer with experience in polymer science or in plastics or analytical chemistry is needed to join a research group of academic and technician staff supported by an S.R.C. Major Centre Special Grant. The successful applicant will be expected to develop methods for the characterisation of chain-extended single crystal polymers produced in the Department of Physics. This will also involve collaboration with the Departments of Chemistry and Materials. Applicants should have an H.N.C. or degree in a physical science, or equivalent qualification or experience. The appointment will be for two years in the first instance on the salary scale (Technician Grade 6) £2,370 by £84 to £2,874 p.a. plus £175 p.a. London Weighting. Five weeks (in total) annual leave. Five day week. Further details of the project can be obtained from Dr. D. Bloor of the Physics Department or write to Assistant Secretary (Establishment) EO/DB. (1808)

EAST MALLING RESEARCH STATION
BIOCHEMIST FOR FRUIT RESEARCH

An experienced biochemist with a good honours degree to study changes in fruit, particularly apples, during storage.

Appointment as Higher Scientific Officer (£2,221 to £2,854) or Senior Scientific Officer (£2,798 to £3,895) according to experience. F.S.S.U. with 4½% non-pensionable allowance to offset personal contributions.

Application forms and further details from the Acting Secretary, East Malling Research Station, East Malling, Maidstone, Kent ME19 6BJ. (1809)

Find your place in British Gas

ELECTRON MICROSCOPIST

London Research Station provides a central analytical service for the Gas Industry involving the development of new methods and the use of specialised techniques. Currently we need a scientist for non-routine electron microscope work.

Duties would involve specimen preparation, microscope operation, interpretation and presentation of results; materials studied include catalysts, special alloys, abraded surfaces, corrosion products, bacteria and plastics.

Applicants should have at least H.N.C. or equivalent with a good physics background and the ability to do delicate manual work. Previous experience of either scanning or transmission electron microscopy would be an advantage.

Starting salary will be according to qualifications and experience on a scale rising to £2,661 or exceptionally £2,913.

For further details and application form, contact the Research Secretary, British Gas Corporation, London Research Station, Michael Road, London SW6 2AD, quoting reference 4000/11/N. (1810)

BRITISH GAS

South African Atomic Energy Board

Pelindaba
Theoretical Plasma Physicist

The Atomic Energy Board is starting a plasma research programme based on a medium sized Tokamak device. Applications are invited from suitably qualified theoreticians to take the part in the research programme. A Ph.D. is preferred. Interest in MHD instabilities will be a recommendation. The commencing salary will be determined according to qualifications and experience.

Fringe benefits include: Medical Benefit Scheme, Assisted Housing loan scheme, housing subsidy scheme, Pension and Group Insurance Scheme, Annual Leave Bonus, ample leave privileges and free transport between Pretoria and the Board's site. A person appointed from overseas will receive financial assistance in regard to travelling expenses and the cost of transporting his furniture and effects including a motor car. He is required to make use of all assistance given by the South African Department of Immigration, the amount received from the said Department will be deducted from the financial assistance offered by the Board. He is also required to serve the Board for two years in consideration of the financial assistance received. A non-South African appointee must undertake to apply for South African Citizenship as soon as he qualifies therefore.

Written applications, giving full details of qualifications, experience, Employer and salary, etc., should be addressed to:

South African Embassy,
Office of the Scientific Counsellor,
Chichester House,
278 High Holborn,
London WC1V 7HE.
(Telephone 01-242 9641). (1804)

ANALYST FOR PHARMACOKINETICS

DEPARTMENT OF METABOLISM AND PHARMACOKINETICS

The Huntingdon Research Centre is the recognised international leader in contract research in the life sciences. As a result of our continuing expansion, a new vacancy exists for a Graduate in our Department of Metabolism and Pharmacokinetics.

The work will mainly involve studies of the metabolic fate and pharmacokinetics of drugs. Candidates should possess an appropriate qualification and should have received formal training in pharmacokinetics, but extensive experience is not essential. Practical ability, particularly in drug analysis, is of prime importance.

This vacancy will provide an ideal opportunity to join one of the leading drug metabolism research groups in the U.K. Attractive career opportunities exist based on merit.

The Centre is located near Huntingdon within easy reach of Cambridge with good access to London by road and rail. We offer excellent working conditions together with progressive general benefits, a competitive salary and the usual pension and other fringe benefits.

Please write or telephone for an application form to Mrs. Nancy McCree, Personnel Officer, Huntingdon Research Centre, Huntingdon PE18 6ES; Tel: Woolley (STD 048 086) 431; quoting reference number 259. (1754)

THE HOSPITAL FOR SICK CHILDREN

TECHNICIAN (biochemical)

Interesting varied cardiac research. Salary: £1,200 to £1,500. Opportunity for higher degree not excluded. Application to Consultant-in-Charge, Department of Clinical Physiology, Hospital for Sick Children, London, W.C.1. (01-405 9200, ext. 126). (1751)

FELLOWSHIPS AND STUDENTSHIPS

LAURA DE SALICETO STUDENTSHIP

UNIVERSITY OF LONDON

Application is invited for the Laura de Saliceto Studentship (part-time) for the Advancement of Cancer Research, value £150 a year for not less than two years. Applications should reach the University not later than June 1, 1974. Further particulars may be obtained from the Secretary to the Scholarships Committee, University of London, Senate House, London WC1E 7HU. (1796)

UNIVERSITY OF NOTTINGHAM

RESEARCH IN ENVIRONMENTAL STUDIES

Applications are invited for a **RESEARCH STUDENTSHIP** and a **RESEARCH ASSISTANTSHIP** in the Environmental Physics Unit, Department of Physiology and Environmental Studies, School of Agriculture.

The **N.E.R.C. RESEARCH STUDENTSHIP** is to study solar and atmospheric radiation on sloping surfaces. Applicants should have, or expect to obtain, a good honours degree in Physics or Engineering. An interest in meteorology and/or biology is desirable.

The **RESEARCH ASSISTANTSHIP** supported by the A.R.C. is to investigate the effects of sulphur dioxide on the gas exchange of crop plants. Applicants should have an honours degree preferably in agricultural or biological science.

Both posts are tenable for three years. The successful applicant for the studentship will be expected to register for a higher degree; the grant is £695 p.a. plus fees. The salary for the research assistant will be on the scale £1,422 to £1,569 (under review). Alternatively a suitable applicant may register for a higher degree at an appropriate salary.

Further details of both posts and an application form may be obtained from Dr. M. H. Unsworth, Environmental Physics Unit, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough, Leics. (1748)

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF CHEMISTRY

Applications are invited from first or second class honours graduates in Chemistry or Biochemistry for an Agricultural Research Council Studentship. The appointment will be for 3 years commencing October 1, 1974 and the successful candidate will study aspects of the biosynthesis and metabolism of plant proanthocyanidins. It is expected that the person appointed will register for a higher degree, for which fees are paid. Students about to graduate in Chemistry or Biochemistry will be considered. Applications as soon as possible to Dr. E. Haslam, Reader in Organic Chemistry, Department of Chemistry, University of Sheffield, Sheffield S3 7HF. Quote Ref. R.66/G. (1761)

Commonwealth of Australia

QUEEN'S FELLOWSHIPS *in Marine Science*

To commemorate the Royal Visit to Australia in 1970, the Australian Government established the Queen's Fellowships Scheme. Under this scheme up to five fellowships may be awarded each year for full-time research by young scientists of exceptional promise and proved capacity for original work. These awards are tenable at the Australian Institute of Marine Science, Townsville, an Australian university of approved research institution normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award.

QUALIFICATIONS Queen's Fellows should have a Ph.D., or equivalent qualifications, or equivalent research or professional experience, in a discipline applicable in marine science.

Awards will, in general, be restricted to applicants who are not more than 30 years of age on the date when applications close.

STIPEND $9,500 (Australian) per annum—increased to $10,250 per annum at age 28 years.

ALLOWANCES are payable in respect of a Fellow's wife ($500 p.a.), each dependent child ($200), superannuation payments (up to 10 per cent of stipend), appropriate insurance coverage and necessary travel expenses. Host institutions are paid an allowance towards the cost of setting up the fellow and his research work.

For those taking up fellowships at Townsville or Perth a travel grant ($500 p.a.) will also be paid to assist consultation with other research workers in Australia.

APPLICATIONS Persons interested in applying for the above fellowships should obtain application forms and a statement of the conditions of award from the Secretary, Queen's Fellowships Committee, Department of Science, P.O. Box 449, Woden, A.C.T. 2606, Australia; Education Liaison Officer, Canberra House, Strand, London, WC2R 3EH, England; or The Consul General, Australian Consulate General, 636 Fifth Avenue, New York, 20, N.Y. 10020, U.S.A. Applications for the award, which will be announced in DECEMBER 1974 close at the Canberra address on 1 July 1974.

FELLOWSHIPS WYE COLLEGE

(University of London)

POSTGRADUATE AGRICULTURAL RESEARCH STUDENTSHIPS 1974

Applications are invited from graduates or from those due to graduate in agriculture, horticulture or related subjects in the summer of 1974 for Ministry of Agriculture, Fisheries and Food postgraduate studentships tenable from October 1, 1974. A first or Upper 2nd Class Honours degree will be expected.

Department of Agriculture

One award for (a) Minimum cultivation systems; or (b) Pig behaviour in relation to nutrition; or (c) Ruminant behaviour in relation to nutriton.

One award for (a) Tractor utilisation and fuel economy; or (b) Technique of dryeration for grain maize.

Department of Horticulture

One award for "Production of spikelets in the ear of cereals".

Department of Biological Sciences

One award in the field of plant breeding in relation to disease resistance.

Value of Award: £695 per annum plus appropriate allowances and expenses.

Applications to the Registrar, Wye College, Wye, Ashford, Kent TN25 5AH, as soon as possible, and in any case not later than June 15, 1974. (1724)

UNIVERSITY OF CALIFORNIA BERKELEY

POSTDOCTORAL FELLOWSHIP IN LIMNOLOGY

Position vacant immediately for a Limnologist to assist in high-quality basic research on causes of blue-green algal blooms in Clear Lake, California, and applications to control nuisance blooms. Knowledge of modern limnological techniques required. Send curriculum vitae and references to Prof. A. J. Horne, Division of Sanitary Engineering, University of California, Berkeley, CA 94720. (1769)

The University of Leeds DEPARTMENT OF PLANT SCIENCES

A N.E.R.C. RESEARCH STUDENTSHIP is available for up to 3 years from October 1, 1974 for a biology graduate with or about to obtain a good honours degree, preferably including some chemistry or biochemistry. The successful candidate will read for a Ph.D. on aspects of cellular heavy metal localisation in marine algae under the supervision of Dr. L. V. Evans.

Applications, with the names of two academic referees, to Dr. L. V. Evans, Department of Plant Sciences, The University, Leeds LS2 9JT. (1778)

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMISTRY
Applications are invited for the post of
POST-DOCTORAL RESEARCH FELLOW

to work with Dr. D. A. Stansfield in investigations of the role of phosphorylation of ribosomal proteins in the cyclic AMP mediated increase in progesterone synthesis in corpus luteum. The project, which is supported by a M.R.C. grant, is to start in October, 1974 and the position is tenable for 3 years from that date.

The person appointed will be working within a small research group currently investigating various aspects of cyclic AMP biochemistry in luteal tissue.

Salary scale £1,929 to £2,058 to £2,223 p.a.

Informal enquiries may be made to Dr. Stansfield in the Department of Biochemistry. Applications, quoting Ref. Est/34/74J and including the names of 2 referees, should reach The Secretary, The University, Dundee DD1 4HN, by May 24, 1974. (1740)

UNIVERSITY OF AUCKLAND
NEW ZEALAND
RESEARCH FELLOWSHIP
MARINE RESEARCH LABORATORY, LEIGH

Applications are invited for a Research Fellowship tenable at the Marine Research Laboratory, Leigh. The Laboratory acts as a research and advanced training facility for the Departments of Botany, Geology, Physics and Zoology. It offers rapid access to a wide variety of unspoilt coastal habitats and has a high quality experimental seawater system and facilities for direct environmental monitoring. Opportunities are particularly good for interdisciplinary environmental studies and work involving close connection between field and laboratory studies. Applicants should have a Ph.D. degree and research experience in some branch of Marine Science.

In the first instance the appointment will be for a period of three years, in the last year of which it will be reviewed by the University Council. Depending on circumstances the Fellowship could be continued for a further period of up to a maximum of five more years.

Salary will be established according to qualifications and experience within the scale for University Lecturers. The present scale for a Lecturer is NZ$6,753 per annum rising to $8,568 per annum by six annual increments.

The Research Fellow will have the opportunity to join the Government Superannuation Fund.

An allowance within approved limits will be made towards travel expenses.

Conditions of appointment and method of application are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on **June 16, 1974.** (1755)

UNIVERSITY OF EXETER
DEPARTMENT OF CHEMISTRY

Applications are invited for two Post-Doctoral Fellowships for work on the nature of the action of (a) glutaraldehyde and (b) penicillins on proteins. The work will involve the isolation of the reaction products by chromatography and gel filtration and the elucidation of the side-chain modifications resulting from the reactions.

The appointments will be for one year in the first instance, from October 1, 1974. (Salary: £2,118 per annum plus F.S.S.U.), and are renewable for a second year (Salary: £2,247 per annum). Applications, with the names of two referees, should be sent to Professor H. N. Rydon, Department of Chemistry, University of Exeter, Stocker Road, Exeter EX4 4QD, by July 12, 1974. Please quote **Ref. 1/12/7070** in all correspondence. (1746)

UNIVERSITY OF EXETER
N.E.R.C. RESEARCH ASSISTANTSHIPS

Applications are invited from candidates with good Honours degrees in Zoology or Biology for two Research Assistantships in the Department of Biological Sciences. The posts are each available from October 1, 1974 and are tenable for three years.

The successful applicants will be required to work under the supervision of Dr. C. R. Kennedy on the Management of the Coars Fish in a Freshwater Lake, and to register for a higher degree in this University. The investigation will be carried out in association with Mr. R. B. Troake at Slapton Ley Field Centre, and is supported by the N.E.R.C.

The Assistantships have a nett value of £695 per annum, plus fees.

Further particulars may be obtained from the Secretary of the University, Northcote House, The Queen's Drive, Exeter EX4 4QJ, to whom applications (5 copies, overseas candidates 1 copy), should be sent to arrive not later than May 30, 1974. Please quote Ref. No. 1/12/7069 in all correspondence. (1747)

THE NEW UNIVERSITY OF ULSTER
AND
DEPARTMENT OF EDUCATION FOR NORTHERN IRELAND
POSTGRADUATE STUDENTSHIPS

For the academic year 1974–75 the Department has allocated a number of quota studentships for postgraduate research leading to the degrees of M.Phil./D.Phil. and for advanced courses leading to the degrees of M.Sc./M.A.

Applications are invited in the following subject areas:

1. **M.Phil./D.Phil.**

School of Physical Sciences
Chemistry—Mathematics—Physics

School of Biological and Environmental Studies
Biology—Geography and Environmental Studies—Psychology

School of Social Sciences
Economics—Human Ecology—Social Administration—Social Anthropology and Sociology.

School of Humanities
Classics—English—French—German—History—Irish Studies—Linguistics—Philosophy—Russian—Spanish—West European Studies

Education Centre
Education

2. **M.Sc./M.A.**

M.Sc.—Economics

M.A.—Classics; Education; English; Contemporary International History; General Linguistics; Russian.

To be eligible for an award an applicant must normally be a British subject ordinarily resident in Northern Ireland and should hodl a good honours degree. Applications may be submitted in anticipation of the results of final examinations for honours degrees.

Application forms and further particulars should be obtained from The Registrar, The New University of Ulster, Coleraine, Co. Londonderry, Northern Ireland (quoting Ref. 74/55) to whom completed applications, including the names and addresses of two referees, should be returned not later than May 27, 1974. (1731)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF ORGANIC CHEMISTRY

Applications are invited for the post of RESEARCH FELLOW to work in collaboration with Dr. G. A. Morrison on the synthesis of steroids of potential pharmacological value. The appointment, from October 1, 1974, will be for one year in the first instance, but may be extended. Salary scale £1,929 to £2,223 (under review), depending upon age and experience.

Forms of application and further particulars from the Registrar, The University, Leeds LS2 9JT (please quote 25/16). Applications should be received as soon as possible. (1762)

LINCOLN UNIVERSITY COLLEGE OF AGRICULTURE
NEW ZEALAND
POST-DOCTORAL FELLOWSHIP

The Council of Lincoln College invites applications for a Post-doctoral Fellowship, tenable in any of the undermentioned Departments.

Agricultural Economics and Marketing; Agricultural Engineering; Agricultural Microbiology; Animal Science; Biochemistry; Entomology; Farm Management; Horticulture; Plant Science; Range Management; Soil Science; Veterinary Science; Wool Science.

The object of the award is to contribute to the research programme at Lincoln College. In addition to carrying out research, the successful applicant will be expected to participate in limited teaching activities without further emolument.

The Fellowship shall have a total value of NZ$7,600, part of which will be available for fares. The salary portion of the emolument is taxable in New Zealand unless a double tax agreement operates between New Zealand and the country of the successful applicant. Tenure will be for one year in the first instance, but may be extended at the discretion of the Council.

Conditions of appointment giving further details of this position at Lincoln College can be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College in Canterbury, New Zealand.

Applications close on May 31, 1974. (1678)

ROYAL HOLLOWAY COLLEGE
(UNIVERSITY OF LONDON)
Egham Hill, Egham, Surrey
CHEMISTRY DEPARTMENT
RESEARCH STUDENTSHIP AND RESEARCH TECHNICIAN

The following research posts, supported by the S.R.C. and sunpervised by Dr. Paul Powell, are available from October 1, 1974.

1. S.R.C.(CASE) postgraduate studentship for work on synthesis of terpenoid compounds using transition metal complexes as catalysts, in collaboration with Bush Boake Allen Ltd.
2. Technician Grade 3 with experience in the routine synthesis of organic compounds to work on mechanisms of reactions of nucleophiles with organic ligands co-ordinated to transition elements. Salary £1,650 by £54 to £1,758 a year, plus superannuation.

Applications together with the names and addresses of two referees should be sent to the Personnel Officer (N) as soon as possible, from whom further details may be obtained. (1759)

THE UNIVERSITY OF LANCASTER
DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for two research studentships, supported by N.E.R.C.,

(a) to study the interractions between lumbricid earthworms and soil micro-organisms;

(b) to examine the effect of insecticides on the physiology of fish muscle.

Applicants are expected to have, or to obtain, a first or upper second class honours degree in a relevant subject and should be prepared to commence study in October, 1974.

Further information is available from The Administrative Officer, Department of Biological Sciences, University of Lancaster, LA1 4YQ, to whom applications, including a brief curriculum vitae and the names of two referees should be forwarded by July 15, 1974. (1735)

ULSTER COLLEGE
THE NORTHERN IRELAND POLYTECHNIC

RESEARCH STUDENTSHIPS

Applications are invited for the award of studentships tenable from 1 October 1974 for research in the following fields of study:-

CHEMISTRY
Photochemistry
Polymer Chemistry
Co-ordination Chemistry (2)
Electrochemistry

BIOLOGY
Microbiology/Bacteriology
Plant Tissue Culture

EARTH SCIENCES
Geology and Mineralogy of Ore Deposits
Geomorphology

The conditions for the award and tenure of the studentships are identical to those of the Research Councils. Further particulars and application forms are available from:-

Academic Registrar,
Ulster College,
The Northern Ireland Polytechnic,
Jordanstown,
Newtownabbey.
Co. Antrim, BT37 0QB. (1732)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BOTANY
S.R.C./C.A.S.E. RESEARCH STUDENTSHIP

Applications are invited from graduates with a first or upper second class Honours degree in Botany, Biochemistry or other relevant subject, or those graduating this year, for one S.R.C./C.A.S.E. Research Studentship, tenable from Otcober 1, 1974.

The research topic is isoenzyme analysis in assessing the purity of commercially important **Brassica** seeds. In addition to work in the Botany Department, seed testing will also be carried out at Asmer Seeds Ltd.

Applications, together with details of academic background and names of two referees, should be received not later than May 30, 1974 by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/N/276001. (1766)

FELLOWSHIPS
THE UNIVERSITY OF MANCHESTER
RESEARCH STUDENTSHIPS IN THEORETICAL COLLOIDS

Applications are invited for two studentships (CASE awards), tenable for up to 3 years from October 1, from candidates with good honours degrees in applied mathematics or in physics or chemistry with a background of mathematics. Successful candidates will register for Ph.D. and will work on (a) theory or absorption of polyelectrolytes; (b) colloid stability theory in hydrocarbon media. They will spend some time in the research laboratory of the co-operating industrial firm: (a) Unilevers; (b) Tioxide International (expenses paid). Applications, giving names of two referees, should be sent as soon as possible to Dr. S. Levine, Department of Mathematics, The University, Manchester M13 9PL. (1728)

AUSTRALIAN CANCER SOCIETY
CANCER RESEARCH FELLOWSHIP

The Australian Cancer Society invites applications for the Postdoctoral Research Fellowship.

The Australian Cancer Society has initiated a Research Fellowship Program. The fellowships are directed at the postdoctoral level and are intended to assist a research worker at this level to become established in Australia.

The Fellowships is tenable in any approved institute in Australia and normally is for one year.

A salary up to $8,500 p.a. is payable, together with $1,000 equipment grant and $500 travel.

Closing date for applications is the first day of August in the year of application.

Application forms and the Conditions of Award may be obtained from:

The Executive Director,
Australian Cancer Society,
P.O. Box 25,
KOGARAH, N.S.W. 2217. (1739)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF BIOCHEMISTRY AND DEPARTMENT OF EXPERIMENTAL PATHOLOGY
RESEARCH FELLOW/ RESEARCH ASSOCIATE

Applications are invited for a post of Research Fellow or Research Associate/Senior Research Associate. The successful applicant will be a member of a small research group working on the immunopathology of muscle under the direction of Professors S. V. Perry (Department of Biochemistry) and P. G. H. Gell (Department of Experimental Pathology). The initial aims of the research will be to isolate and characterise proteins from human muscle, study their immunochemistry and evaluate the role of antibodies to them in the aetiology and diagnosis of muscle disease. The successful applicant will undertake the biochemical part of the investigation which will be carried out in close association wth a larger research group engaged in a fundamental study of muscle biochemistry that is located in the Department of Biochemistry.

Applicants should be of post-doctoral status and have had experience in protein chemistry and fractionation procedures; experience of immunochemistry would be an advantage but not essential. The appointment is supported by a five-year grant from the Muscular Dystrophy Group of Great Britain and the salary will be in the range £1,929 to £2,223 (Research Fellow) or £1,569 to £3,048 (Research Associate/Senior Research Associate) plus F.S.S.U. Further particulars from the Assistant Registrar(S), Universoity of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications, including names of two referees, should be submitted by May 31, 1974. (1765)

MISCELLANEOUS

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

A vacancy for a Typist full or part time is presently available for someone, who could take an interest in the activities of the British Association.

Apply to the Secretary, 23 Savile Row, W1X 2AA. 01-734 6010. (1773)

FOR SALE AND WANTED

Always wanted:
BACK RUNS OF JOURNALS
IN SCIENCE AND THE HUMANITIES
WM. DAWSON & SONS LTD.
Back Issues Department,
Cannon House, Park Farm Road,
Folkestone, Kent, England.
Tel.: Folkestone 54421. (1)

LECTURERS

UNIVERSITY OF DUBLIN
TRINITY COLLEGE

JUNIOR LECTURER IN ZOOLOGY

Applications are invited for the above position. Preference will be given to candidates with experience either in Physiology, Physiological Ecology or Behaviour.

Salary scale: £1,969 x £126 - £2,473 (under review).

Marriage and children's allowances are paid and there is a non-contributory F.S.S.U.-type Pension Scheme.

Further particulars and application forms may be obtained from:

The Staff Secretary,
West Theatre,
Trinity College,
Dublin 2.

who will receive completed applications until Monday, May 27, 1974. (1805)

UNIVERSITY OF ADELAIDE

Applications are invited for the following appointments:

LECTURER IN GEOGRAPHY (BIOGEOGRAPHY). Preference will be given to candidates interested in plant and animal geography, ecosystem structure and function, and ecology related to resource management. From January 1, 1975 (31.5.74).

LECTURER IN GEOGRAPHY. Preference will be given to applicants qualified to teach geomorphology and soil geography, with particular reference to Australia. From January 1, 1975. (31.5.74).

Salary scale: Lecturer $A8,698 by $A470(1) by $A469(6) to $A11,982; with superannuation on the F.S.S.U. basis. Initial salary will be fixed within the scale in accordance with qualifications and experience.

Further particulars about these posts and the conditions of appointment and other information sought will be supplied on request to the Registrar of the University, or to the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London, WC1H 0PF.

Applications should be sent in duplicate and giving the information listed in the Statement that will be supplied, to the Registrar, the University of Adelaide, North Terrace, Adelaide, South Australia, 5001. (1807)

LIVERPOOL POLYTECHNIC
DEPARTMENT OF BIOLOGY
LECTURER II IN ANIMAL ECOLOGY

Applications are invited for the post of Lecturer II in Animal Ecology. Applicants should have a special interest in Fresh Water or Marine Biology and have pursued a research problem, the level of Ph.D.

Salary £2,700 to £3,474 p.a.

Details available from Staff Office, Dept. N, Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool L3 9RH. (1803)

GRANTS AND SCHOLARSHIPS

DUBLIN INSTITUTE FOR ADVANCED STUDIES

SCHOOL OF COSMIC PHYSICS

The Governing Board of the School of Cosmic Physics invites applications for post-doctoral RESEARCH SCHOLARSHIPS tenable in the ASTRONOMICAL and GEOPHYSICAL Sections of the School during the academic year 1974–75 commencing October 1, 1974. A limited number of stipends within the range £1,480 to £1,680 per annum, depending on experience, will be available. Awards will be made for one year in the first instance and may be renewable for one further year.

For further particulars and Forms of Application candidates should apply immediately to **The Registrar, Dublin Institute for Advanced Studies, 10 Burlington Road, Dublin 4, Ireland.** Completed applications should reach the Registrar on or before 10th June, 1974. (1777)

UNIVERSITY OF SYDNEY

F. H. LOXTON POST-GRADUATE STUDENTSHIPS OR SCHOLARSHIPS IN CHEMICAL ENGINEERING

Applications for the abovementioned awards are invited from male graduates of any age and of any Australian or overseas university.

The award may be a Studentship ($A3,050 per annum) or a Scholarship ($A3,200 to $A4,150 per annum) according to the applicant's qualifications and research experience. It is tenable for one year in the first instance, but may be renewed for a second or third year, and, in exceptional circumstances, for a further year.

Areas of current research interest are Biochemical Engineering, Computer-aided Design, Computer Process Control, Distillation and Mass Transfer, Environmental Engineering, Minerals Engineering, Plasma Pyrometallurgy, Solids and Particle Technology, Reaction Engineering, and Systems Engineering.

Further information and application forms may be obtained from the Registrar, The University of Sydney, N.S.W. 2006, Australia, with whom applications close on **May 24, 1974.** (1727)

UNIVERSITY OF SYDNEY

THE THOMAS LAWRENCE PAWLETT SCHOLARSHIP

Applications are invited for the above-mentioned award from suitably qualified graduates who propose to undertake postgraduate study and research (normally for a higher degree) in the Faculty of Agriculture at the University of Sydney.

The Scholarship is tenable for one year, and may be renewed from year to year if the holder makes satisfactory progress. The present value is $A3,050 per annum, with allowances.

Applications close on **May 24, 1974** with the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom application forms and full information about the Scholarships are available. (1726)

*Nicotinamide-adenine dinucleotide (NAD)

This compound has been found to be the substrate for the synthesis of the new polymer[1], poly ADP-ribose, which was isolated from animal cell nuclei. The monomer unit is ADP-ribose which is glycosidically linked between the 1′ carbon of the terminal ribose and the 2′ hydroxyl of the nucleoside ribose of the adjacent unit.
DPN [Adenine-2, 8-^{3}H] is suitable for the synthesis of this new polymer. It has been enzymatically synthesized and is offered biologically pure.

May We Re-introduce a Perennial Aldrich Favorite

N-methyl-N′-nitro-N-nitrosoguanidine (MNNG)

The very first product offered by Aldrich was *N*-methyl-*N*′-nitro-*N*-nitrosoguanidine (MNNG), sold solely as a precursor for diazomethane. Beyond a doubt, it is the most convenient precursor : stable, beautifully crystalline, generating diazomethane with **aqueous** alkali.[1] However, it has serious drawbacks. It is the most powerful mutagenic agent[2] known and some people exposed to it develop a skin sensitivity. Also, the crude MNNG as obtained from the aqueous nitrosation is pyrophoric. The recrystallized product is not, and furthermore, it is so nicely crystalline that it can be weighed easily without contact with the skin.

For larger scale production of diazomethane, our Diazald® has advantages over MNNG. It is not a skin irritant and it costs much less. However, Diazald® has two disadvantages: *(i)* a shelf-life of only one to two years, and *(ii)* the generation of diazomethane requires **alcoholic** alkali, aqueous alkali being ineffective. Thus, many scientists, particularly biochemists, who require only small quantities of diazomethane have continued to use our MNNG.

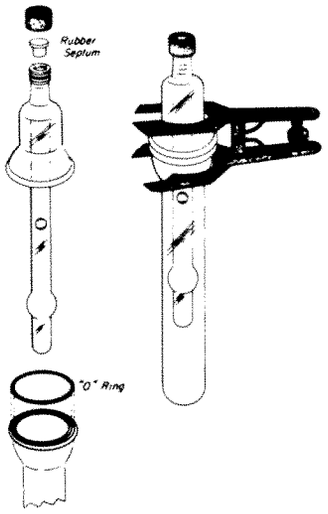

Figure 1. Apparatus for preparing diazomethane • **Z10,100-1 and Z10,102-8**

• Reprinted with permission from *Anal. Chem.*, **45**, 2302 (1973). Copyright by the American Chemical Society.

The standard preparation of diazomethane involves adding MNNG to a cold 50% aqueous potassium hydroxide solution covered with ether, and then codistilling the diazomethane with the ether. Diazomethane has been reported to be explosive, particularly on contact with ground glass joints, and so generations of chemists have watched this codistillation with trepidation. We now offer two sets of apparatus which allow safe, more convenient generation of diazomethane either with or without distillation.

The first of these enables the preparation of diazomethane from MNNG **without distillation.**[3] Thus, MNNG is placed in the inner chamber and cold ether is introduced into the outer chamber of the apparatus (fig. 1, millimole or micromole size). 5*N* sodium hydroxide is then injected through the silicon septum onto the MNNG and diazomethane collects in the ether, ready for use. Higher diazoalkanes can be prepared from our other *N*-alkyl-*N*′-nitro-*N*-nitrosoguanidines (ethyl, propyl, butyl, are available), as can their deuterated and tritiated analogs.[4,5] Our Diazald® Kit for the generation of diazomethane from Diazald® features smooth Clear-Seal® joints which avoid the hazards associated with ground glass joints. Deuterated diazomethane is easily prepared using our Deutero Diazald® Prep Set which contains instructions and chemicals necessary for generating 50 mmoles of deuterated diazomethane.

12,994-1	***N*-Methyl-*N*′-nitro-*N*-nitrosoguanidine** **10g $10.00; 14.7g† $15.50; 25g $22.00**

Calculator convenience, computer facilities

Calculators are undeniably easy to operate: you enter the data, select the operation, and the machine gives the answer. With a normal computer you have to have everything perfect to start with — otherwise all you get is an error message.

The WANG 2200 is a calculator with all the facilities of a computer: a programming language—BASIC, peripherals, lots of storage. It is self-contained and modular — you can start with a low-cost system and add storage and peripheral facilities as you need them.

The statistics calculator with "BASIC"

We made the WANG 2200 easy to use. Programming is in BASIC, the simplest, most understandable language there is. You input a BASIC word with one single, silent keystroke. You see the calculation progressing on the screen, you check, correct, and learn more about your program. Any error is marked by a coded arrow.

The BASIC is standard Dartmouth, so most existing programs will work. And WANG supplies a range of statistical, mathematical and technical programs free of charge. With the peripherals available you can build the system you need.

Up to 32K of computing power

The WANG 2200 has up to 32K bytes of program storage. Disk storage for 5 million characters is available. And if necessary, it can be used as a terminal. Whatever power your problem needs, the WANG 2200 can provide it.

Plus alphabet work

Any computer can work with numbers. The WANG 2200 processes letters and symbols too.

Wang, the specialists in scientific calculators

Wang laboratories have been making electronic calculators for more than ten years. We made many of the innovations that made programmable calculators possible, gave them peripherals; increased their power.

WANG calculating systems are sold and serviced in more than 40 countries.

MILLIPORE®

Guide to authors

Nature accepts three types of communications:

● Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

● Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

● 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (*a*) is preferred to e^a if '*a*' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Cell-free studies of developmental changes in synthesis of α-foetoprotein and albumin in the mouse liver—*T. Tamaoki, K. Thomas and I. Schindler* 269

Blocking of syngeneic effector T cells by soluble tumour antigens—*F. Plata and J. P. Levy* 271

Allogeneic stimulation modulates the *in vitro* response of T cells to transplantation antigen—*K. J. Lafferty, I. S. Misko and M. A. Cooley* 275

Cannabinoid content of some English reefers—*J. W. Fairbairn, I. Hindmarch, S. Simic and E. Tylden* 276

Evolutionary divergences between populations of Australian wild rabbits—*J. McCluskey, T. J. Olivier, L. Freedman and E. Hunt* 278

Claim that two human linkage groups carry different loci for GPT and LDH withdrawn—*H. van Someren, P. M. Khan, A. Westerveld and D. Bootsma* 279

Connective stability of complex ecosystems—*D. D. Siljak* 280

Palatability dynamics of cardenolides in the monarch butterfly—*L. P. Brower and C. M. Moffitt* 280

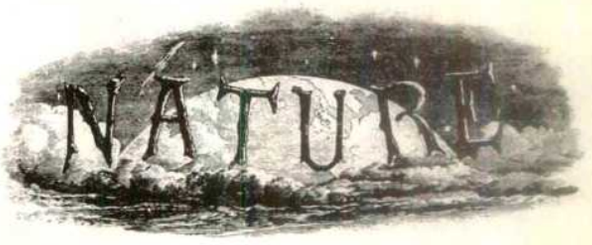
ESF—low budget but higher profile

A EUROPEAN SCIENCE FOUNDATION (ESF) moves closer to reality with the recent meeting in Stockholm of representatives of almost all western European countries at which, after strong competition from Dublin and Leiden, Strasbourg was chosen as the site of the foundation's offices. The general outlines of the statutes were also approved and the next meeting of administrators will be in November at which time the constitution should have been drafted. Membership now seems to be resolving itself—only Portugal (an understandable and presumably temporary absence) was missing from western Europe, Finland sent an observer and Yugoslavia has had second thoughts and dropped out. "The door is open", one delegate said, "for eastern Europe to join, and it would be my hope that within a few years the membership would be truly pan-European". Within a year a President and a Secretary-General should be installed and a secretariat of about ten is anticipated in Strasbourg.

The ESF has had an unusual history and it bears a deceptive name. It was created out of a desire to pre-empt, rather than in obvious response to an immediate need. Administrators throughout Europe saw the growing danger, a few years ago, of a deadening hand from the European Economic Community (EEC) seizing science policy and attempting to run science from Brussels. This caused alarm for two reasons: nobody had much stomach for Brussels bureaucracy and international science policy making cannot stop at the frontiers of the Common Market. The ESF thus emerged to pre-empt the EEC—it is freely admitted that the driving force was fear that the community would otherwise do something of its own. The title is somewhat of a misnomer since, at least in English-speaking countries, ESF suggests a European version of the American National Science Foundation. This it is not. Science has its more continental meaning of learning (the British Academy and the Royal Society are both involved), and it is not planned that the ESF should hand out grants for research.



Is all of this a good thing? Scientists in general display little interest in supranational schemes, whether international or regional, until they can see concrete examples of benefit to themselves that can be obtained no other way. Multinational ventures in providing expensive facilities are obviously approved by many, but international associations to cover specialisations are more ambiguously viewed and the ESF will fall into this category. To the extent that they organise grand conferences, publish bulletins and attempt to impose standards they are often ineffectual and even disliked. Their lack of funds for the support of research writes them off for many for whom the only organisations worth respecting are fund-giving organisations. And yet they fulfil one purpose which alone justifies their existence—that of representation direct to governments. An international union may mean nothing to a scientist in an affluent and enlightened country, but to one in less happy circumstances it may mean the moral support that leads to a government grant, permission to work abroad for a spell or even such mundanities as the price of an airline ticket.

It is to this mode of working that the ESF should try to restrict itself. If it is seen to be an inexpensive operation (with a budget remaining below the half-million dollar mark), which can act quickly as a lobby for scientists when rational intervention is needed and which can act as a matrix on to which multinational schemes can be assembled but off which they can rapidly be removed, then it deserves support. If it attempts to become more grandiose, and a hunting ground for the power brokers and bureaucrats of science, it must be stopped by scientists themselves taking action.

Between now and November the administrators have one important job to do—to increase scientists' awareness of the existence of the ESF. A press release about the selection of Strasbourg had yet to reach Britain, a week after the meeting ended. When Sir Brian Flowers (Flora Europea as one wag described him) announced the selection to a dinnerful of physicists the stirring of coffee cups continued unabated. There is no plan that the articles of the constitution should be open for any public discussion before November. This last is particularly unfortunate. Although the point is made that they will in the main be boring, they must inevitably contain a description of what the foundation can and cannot do. Too often scientists exert themselves with organisations only to find themselves up against administrative answers —"we have no charter to do this", "we would like to help but our constitution forbids" and so on. It would be good to think that here was one organisation which was understood by European scientists before it began.

Nobody yet knows what the ESF will do. It will do nothing at all unless scientists can be persuaded to see its value and to use it intelligently. This means a higher profile in the next few months.

100 years ago

THE President of the Institution of Civil Engineers and Mrs. Harrison held a reception on Tuesday evening in the western gallery of the International Exhibition, at which over two thousand guests were present. In addition to the picture galleries and rooms containing machinery in motion, the west quadrant was open, and in it were placed illustrations of recent scientific inventions specially lent for the evening. With the exception of Mr. Crook's experiments showing attraction and repulsion accompanying radiation, and Tisley and Spiller's compound pendulum apparatus, all were applications of scientific inventions to the wants of life, if wicked war may be included among our wants, for Sir W. Armstrong, and other firms, sent models of appliances for the hydraulic mounting of large guns, whereby they can be placed in position with ease.

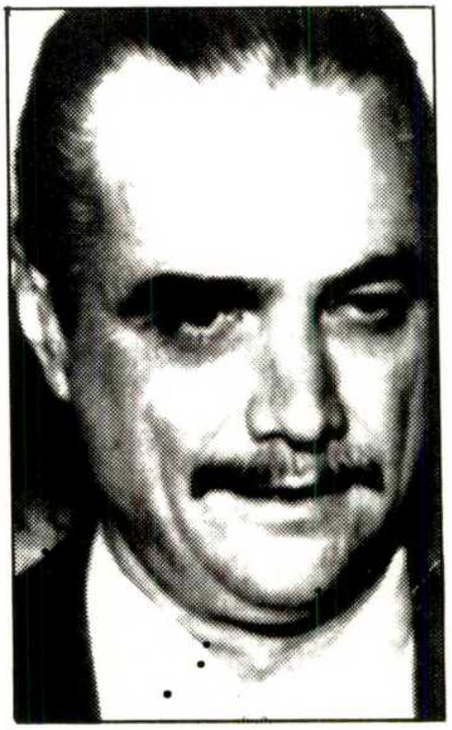
The significance of the invisible millionaire

Peter J. Smith investigates Mr. Hughes's increasing interest in the ocean floor.



Glomar Challenger: played a part in the discovery of minerals.

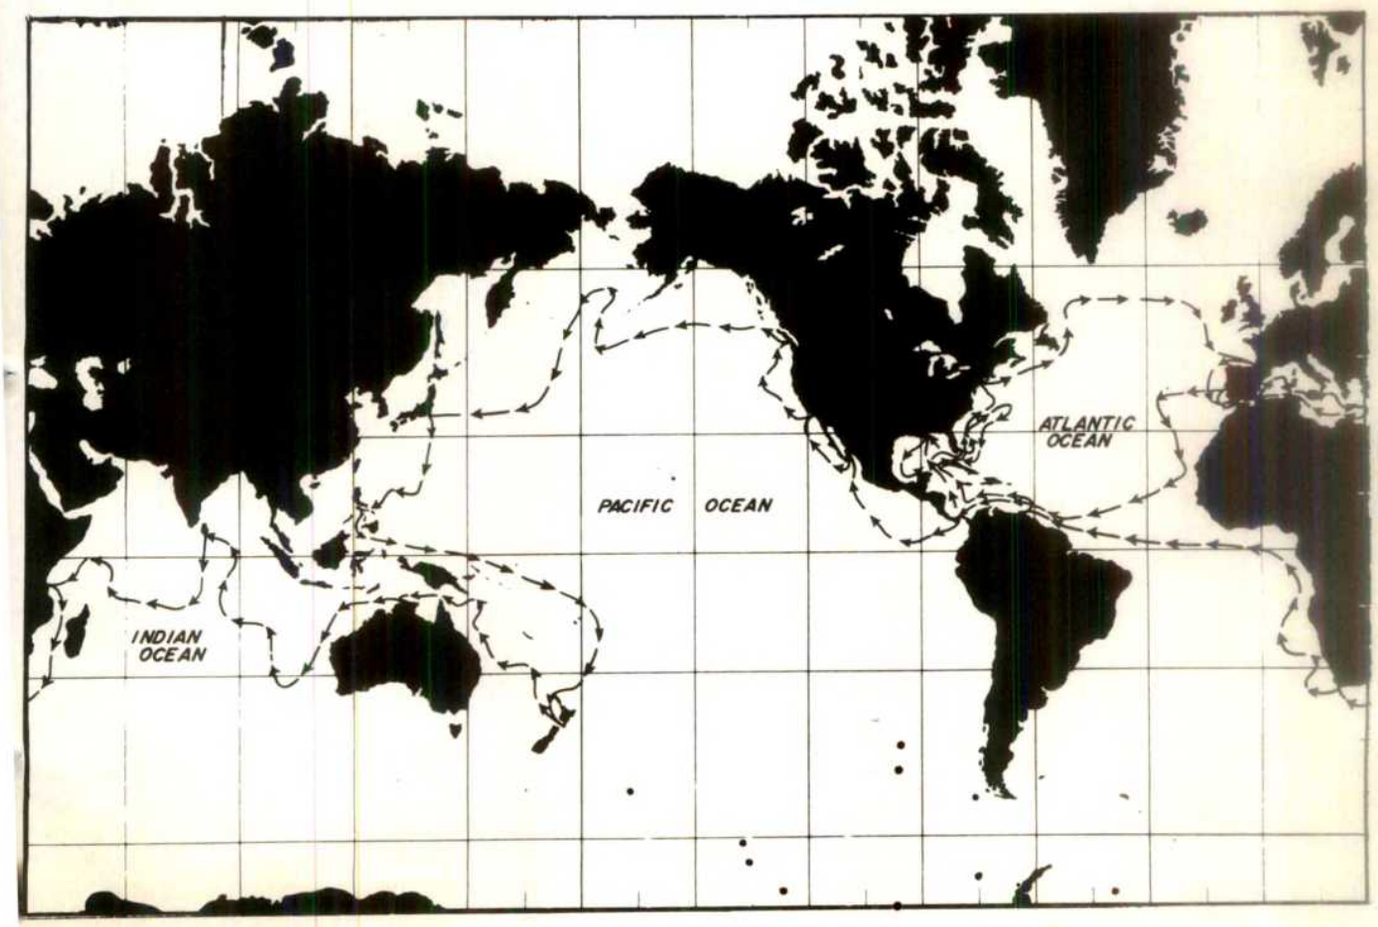
HOWARD HUGHES, invisible millionaire and founder of Trans World Airlines and much else besides, is a celebrity; his comings and goings, his doings and undoings, and his deeds and alleged misdeeds seem to be a source of fascination to many in the western world. But earth scientists in general, and oceanographers in particular, should be taking a much more serious interest in the activities of Mr Hughes, some of which are likely to have severe repercussions for everyone who values the freedom to pursue research on, in and under the world's oceans. That such interest is apparently nil, or at least remains unexpressed, must be counted as one of the most remarkable examples of scientific hypocrisy since the hearts of the physicists who had worked on the Manhattan Project bled over the annihilation of Hiroshima.

The problem arises because Mr Hughes has recently sent to sea the most advanced marine mining vessel in the world, the Glomar Explorer, designed and built in secrecy in Los Angeles by the firm of Global Marine Inc. And joining this ship off the coast of Nicaragua will be a large submersible barge constructed in equal secrecy by the Ocean Systems Division of Lockheed. Naturally, few details of these craft are available, although the submersible is known to be a 90 m x 30 m roofed structure which will be held in place beneath Glomar Explorer by docking legs and tubular stability controls 45-m long. A steel pipe passing through the ship's bottom will then be connected by divers to a dredgehead 15 m wide on the barge, whence a dredge pipe weighing about 4×10^6 kg will be lowered several thousand metres to the ocean floor. At the bottom of the dredge pipe will be equipment to skim the material off the surface of the ocean floor rather like a giant vacuum cleaner.

The object of this paraphernalia is, of course, to collect the copper, manganese, nickel and cobalt-rich nodules which lie on the floor of the Pacific; and although the Hughes equipment is still at the trial stage, this particular project is believed to be the most advanced of several undergoing development with similar aims. The rewards of success are likely to be high, which is presumably why Mr Hughes has been willing to invest so much hard cash in what seems at first sight to be such a risky venture. But the rewards of being first in the field will be what a rival of Mr Hughes has described as "phenomenal", for first-comers will have the joy of being able to undercut (some believe drastically) the high and ever-rising world prices for minerals.

Hughes: first in the field

It must be recognised, however, that any success that Mr Hughes might have in mining the ocean floor has important implications for anyone whose interest in the oceans is purely scientific. For one thing, it is already clear that Mr Hughes must have profited greatly from Global Marine's experience in the building, equipping and operating of the Glomar Challenger, the research vessel that has been used extensively by oceanographers to drill the oceanic crust in the search for evidence to support the new global tectonics. This is true not only of the technology involved but also insofar as the Glomar Challenger has played some part in the discovery of the minerals themselves. So one question which needs to be asked is whether it is right that an individual or company with purely commercial interests should benefit so directly and obviously from a project financed from public funds. The issue is an important one, even though it may not be possible in the end to reach a consensus on the right policy to adopt.



To the extent that the principal participants are American, it may also be thought to be an issue with political ramifications largely internal to the United States. But it is not quite as simple as that. The fact is that much of the mineral wealth of the ocean floor that is likely to be mined lies below what, for want of a better phrase, are called international waters; and some companies with interests in this field have been reported as saying that they will move into such waters whatever

anyone else may think, say or do. One of the practical advantages of so doing, of course, is that profits will be enhanced by the lack of mining taxes payable. But more important, any such move into international waters by a private company, or even by a single nation for that matter, would be contrary to a United Nations resolution declaring the riches of the ocean a common heritage to be shared by all mankind. If this resolution is contravened, and if the forthcoming Law of the Sea Conference fails to agree on a policy to control ocean exploration for the common good (or even if the conference agrees a policy which is later contravened), then as Lord Ritchie-Calder has pointed out, "it isn't hard to see armed conflicts between nations as a result". Moreover, Ritchie-Calder notes that "Hughes may have found a new place to hide—the bottom of the sea—but he won't long be there alone. These industrial privateers are going in for a system much like opencast [strip] mining. Some will do their primary refining at sea, dumping acid and alkaline wastes and tailings overboard. Nobody knows what effect this will have on ocean ecology".

None of this may come to pass, of course; but it affects earth scientists and oceanographers nonetheless, simply because it is possible. And this is where the hypocrisy comes in. During the past year or so several oceanographers have gone out of their way to deplore publicly the threat to basic research from ever expanding national claims to sovereignty over what are now regarded as international waters. The threat is real, but those writers who publicise it disingenuously avoid saying anything about why it exists. One of the reasons is precisely the fear and suspicion of being exploited by more powerful nations—fear and suspicion which are fed by the activities of Howard Hughes and those with similar aims. Oceanographers, and oceanographers in the United States in particular, really should not underestimate the strength of feeling on this issue, not only in the so-called underdeveloped countries but also in those industrialised nations unable to afford the technology for undersea mining.

The Glomar Challenger has played some part in the discovery of the minerals themselves. So one question which needs to be asked is whether it is right that an individual or company with purely commercial interests should benefit so directly and obviously from a project financed from public funds.

There is no doubt a real danger that certain countries will seek to prevent or restrict basic research work by outsiders within several hundred kilometres of their shores, and this may be a blow to science. But if this is to be avoided, these oceonographers who deplore the danger must be equally outspoken against those who feed the fear of exploitation; and the earth science community as a whole must make it clear where it stands on the "common good" resolution passed by the United Nations.

OCEAN drilling routes. For 30 months during the extension period of the Deep Sea Drilling Project, the Glomar Challenger followed the routes indicated below in three oceans and the Mediterranean Sea. The extension drilling was planned for 15 legs of duration two months each, starting in the Gulf of Mexico in February 1970. Other legs followed in the Atlantic Ocean, Mediterranean Sea, the Pacific Ocean, Indian Ocean and ending again in the Atlantic Ocean. These routes followed closely areas expected to yield information concerning the interactions of the movements of continental and oceanic crustal areas. Scripps Institution of Oceanography was managing institution for the project under contract to the National Science Foundation. Builders of the vessel were Global Marine Inc., of Los Angeles.

international news

Concerted criticism of breeder reactors

Colin Norman, Washington

DURING the past couple of weeks, the Atomic Energy Commission (AEC) has been taking a savage public battering over its plans to develop the liquid metal fast breeder reactor (LMFBR) as the keystone to the entire nuclear power programme in the 1990s and beyond. Charges of biased statements, suppression of information, outright deception and other underhand dealings, which are not unusual in Washington these days, have been levelled at the AEC while it has been scrambling to meet a court-ordered deadline of June 14 to produce a final detailed analysis of the environmental, economic and social implications of the LMFBR programme.

Although the AEC is by now used to impassioned attacks by environmentalists and nuclear critics, many of whom are bent not just on stopping the LMFBR programme but also on halting the rest of the nuclear power industry, it may have a more difficult time in defending itself against a particularly devastating critique which was delivered early last week, for it came not from avowed nuclear critics but from another agency in the federal government—the Environmental Protection Agency (EPA).

It is not difficult to see why the LMFBR programme has raised passions in the United States, for in the words of Barry Commoner, the outspoken environmentalist and leader of an organisation called the Scientists Institute for Public Information (SIPI), the country is now "at a crossroads" in its energy policies. A decision to push ahead rapidly with the development of the LMFBR would lock the United States into a nuclear-dominated energy supply programme if for no other reason than the huge cost that the LMFBR would entail. On the other hand, if nuclear critics can nip the LMFBR programme in the bud, they argue that the federal government would be forced to pay more attention to the development of renewable energy resources and energy conservation. The LMFBR has thus become a rallying point for a powerful coalition of environmentalist and scientific groups.

The debate is centred on a landmark decision of the federal appeals court which last year forced the AEC to obey the dictates of the National Environmental Policy Act (NEPA) by producing a broad and detailed analysis of the environmental impact of the commercial application of several hundred LMFBRs. The decision forced the AEC to examine the advantages and disadvantages of the entire LMFBR programme in relation to other methods of producing energy, and the impact statement should therefore form the basis for a public examination of the United States energy policies.

The AEC produced a draft of the NEPA impact statement on March 14 and it is legally empowered to put the statement into final form by June 14. It is the draft statement which is the basis of the AEC's public mauling. The Natural Resources Defense Council (NRDC), a public interest law group, has charged that the draft statement is "a deliberate attempt to mislead the public" and has demanded that it be withdrawn and rewritten. Similarly, the SIPI has castigated the AEC for producing an impact statement which is "so grossly inadequate as to prevent rather than enhance public discussion of the AEC decision to proceed with the programme". And finally, although using rather more restrained language, the EPA has given the AEC's draft statement its lowest possible rating and said that it "does not adequately detail the potential environmental impact" of the programme. In fact, the EPA said that the document was so deficient that it does not provide enough information to allow anybody "to reach the conclusion that the present LMFBR programme is preferable to other energy options".

The EPA's critique has placed the AEC in an unenviable position, for it has hit a number of the most sensitive points in the AEC's justification for the LMFBR programme. If the AEC does alter its statement accordingly, a number of its chief arguments could well disappear, whereas if it ignores the EPA's comments it will lay itself wide open to a court suit by environmentalist groups.

One of the AEC's chief justifications for the LMFBR programme is that breeder reactors are much more efficient than conventional light water reactors (LWRs) in their use of scarce uranium resources. The LMFBR can take uranium-238, which is unsuitable for use in LWRs, and convert it to plutonium which can then be used to fuel both conventional and breeder reactors—it breeds fuel, in other words. Since the AEC predicts that the United States has only enough uranium left to fuel conventional reactors for another 25–50 years, this characteristic of the breeder reactor will be essential for stretching out uranium resources, and it will make the LMFBR the keystone of the nuclear power programme.

The AEC's draft statement estimated that if all goes well the breeder reactor will be introduced in 1987, that 400 of them will be operating by the year 2000 and producing 400,000 MW of electricity and that by the year 2020 LMFBRs will be generating 2.2 million MW. The commission argued that there is no other technology on the horizon which seems capable of supplying that much energy and that to abandon the LMFBR programme now could well plunge the United States into a severe energy crisis towards the end of the century.

The AEC paints this picture of what will happen if the LMFBR is not introduced: as uranium resources dwindle, the cost of mining uranium ore will increase, and this in turn will increase the cost of generating electricity by LWRs and drive up electricity prices. A central theme is that the later the breeder is introduced, the smaller will be the benefits it produces, and therefore a strong commitment must be made as early as possible to the LMFBR programme.

But the NRDC has pulled the AEC's cost-benefit analysis to pieces, suggesting that it is founded on dubious assumptions, unrealistic projections and misleading accounting procedures. And the EPA has backed up most of the NRDC's complaints, suggesting that if the cost-benefit analysis is corrected, it would "preclude acceptance at this time of the AEC contention that deferral of the present LMFBR programme would be intolerably costly". The critique goes on to suggest that there is no reason to rush into the LMFBR programme because "there is sufficient time to consider alternative uranium-saving nuclear technologies and study and resolve some of the issues of environmental risk".

Those statements and the accompany-

ing documentation in the EPA's 94-page critique of the impact statement are likely to provide environmentalist groups with powerful ammunition if they eventually go to court to get the LMFBR programme stopped and, according to one EPA source, if the AEC does amend its impact statement by incorporating some of EPA's criticisms, the economic justification for the breeder could be shot to pieces.

As for the question of plutonium toxicity, that is likely to provide a considerable headache for the AEC for a long time to come. The draft NEPA statement concludes that the entire breeder reactor programme is likely to cause only 2.2 deaths in the United States through radiation from power plants, fuel reprocessing plants and waste disposal facilities. This statement was made in spite of acknowledgments elsewhere in the AEC's document that there is a good deal of uncertainty about the health effects associated with plutonium.

One of the chief uncertainties is the question of potential damage to the lungs from tiny particles of plutonium which have been inhaled, a topic which has recently been thrust into the public spotlight by two nuclear experts working for the NRDC, Dr Arthur Tamplin and Dr Thomas Cochran. Even before the draft impact statement was published, Tamplin and Cochran launched a vigorous attack on the AEC's radiation standards, contending that they are based on an unrealistic assumption that radiation from inhaled plutonium particles is evenly distributed throughout the lungs. They argue that tissue immediately surrounding a particle of plutonium is getting a radiation dose of about 4,000 rems a year, but if the dose is averaged out over the entire lung, it amounts to only 0.003 rems per year. They therefore argue that the AEC should modify its regulations governing the release of plutonium into the atmosphere by a factor of 115,000.

Although the EPA critique takes up no position on the validity of Tamplin and Cochran's theory, it says that "a scientific basis for estimating health effects from plutonium particulates is not available at this time". The EPA therefore recommends that the AEC's final environmental impact statement should indicate what steps the commission would take if the Tamplin–Cochran thesis turns out to be correct, and it also suggests that "as a final alternative, the commission may want to examine what tradeoffs exist in delaying the implementation of a full-scale commercial LMFBR programme until the risks from particulate doses, as compared to those from a uniform lung dose, are on a more firm scientific basis so that meaningful public judgment on the risks and benefits of the programme is possible".

As for the safety of the LMFBR, the EPA critique of the draft impact statement says that the AEC has not been sufficiently qualitative in its assessment for the EPA examiners "to conclude what safety approaches will be taken in many important areas". It is suggested that the AEC should include in its final impact statement a comparison of the risks of the LMFBR and the LWRs.

In view of the serious deficiencies which have been unearthed in the AEC's draft impact statement, the EPA has recommended that AEC lawyers should go to court to get an extension of the June 14 deadline for producing the final impact statement, while the SIPI and the NRDC have suggested the more drastic step of writing another draft statement and following that up with a final document.

Whether or not the AEC sticks to the present deadline, it can be certain that its final impact statement will be challenged in the courts if it fails to meet the objections raised by EPA or other critics

Commoner lays into AEC

ONE of the most stinging criticisms of the Atomic Energy Commission's draft environmental impact statement on the liquid metal fast breeder reactor (LMFBR) programme has come from Barry Commoner, an outspoken champion of the environmentalist movement. Commoner has charged in two press conferences that the Atomic Energy Commission (AEC) has been deliberately suppressing information on the potential of solar energy in order to make its case for the breeder reactor look good.

The accusation stung, for AEC chairman Dixie Lee Ray immediately put out a statement labelling the charge "totally false" and has steadfastly maintained that the commission is not trying to suppress any information relating to the LMFBR programme.

The nub of the dispute is this. Commoner, who is chairman of the Scientists' Institute for Public Information (SIPI) maintains that the AEC's draft impact statement fails to take into account a very optimistic report on the potential for solar power which was prepared for Dr Ray last year. The report, prepared by a panel of experts which assisted Ray in putting together her recommendations for a five-year energy research and development programme, concluded that solar power technologies could be developed to produce about 21% of the electrical energy needs of the United States by the end of this century.

The AEC's draft statement, however, said that "the outlook appears to be that solar energy has little potential as an economic, major source of electricity for several decades" and it went on to suggest that "the use of solar energy will not materially reduce the need for alternative electrical energy sources in the foreseeable future". The impact statement makes no reference at all to the panel's report.

The dispute about solar energy is central to the debate about the need for the LMFBR programme because, if the panel's projections prove to be correct, solar energy would be able to supply almost as much power as the breeder reactor by the year 2000 (see Table 1). And that would shoot to pieces the AEC's contention that the breeder reactor is desperately needed to avoid an energy crunch toward the end of the century. Commoner contended in his first press conference on the matter that "the AEC may be involved in another Washington coverup —this time an attempt to cover up the Sun".

According to the SIPI, which together with the Natural Resources Defense Council brought the suit which forced the AEC to produce the impact statement on the LMFBR programme, the statement's failure to consider solar energy as a viable alternative to the breeder programme is "a gross dereliction of the AEC's duty to the demands of NEPA [the National Environmental Policy Act] and the courts".

Table 1 Summary produced by SIPI of contributions to projected United States electrical demand (year 2000)

Energy source	Generating capacity (millions kw)	Percentage of projected demand
Solar technologies		
Photovoltaic	140	7
Solar thermal	40	2
Heating and cooling of buildings	35	2
Wind	170	9
Ocean thermal	Not available	Not available
Bioconversion	25	1
Total, solar technologies	410	21
Geothermal	80	4
Conservation of electricity	236 (minimum)	12 (minimum)
Grand total	765	37
LMFBR programme	435	23

Alkali Inspectorate still at first base

Eleanor Lawrence

HER Majesty's Alkali and Clean Air Inspectorate comes under strong criticism in a recent report for its attitude to the problems of pollution control which, says the report, is now out of date and often ineffective. (*The Alkali Inspectorate*, Social Audit, 9 Poland Street, London W1V 3DG, £1).

The report, prepared by Maurice Fraenkel for Social Audit, criticises the inspectorate for not publishing the detailed data it collects and for general secrecy and non-cooperation towards members of the public and local authorities who make complaints against specific works. Also, says the report, it seems unwilling to put the maximum pressure on factories who do not comply even with its standards.

These specific criticisms stem from the way the inspectorate itself sees its role in controlling industrial pollution. In the words of the present Chief Alkali Inspector, Mr F. E. Ireland, the first Chief Inspector, Dr Angus Smith in 1863 "set the policy pattern of the inspectorate which has been followed ever since". This policy involved a sympathetic approach towards the manufacturers which included technical help towards solving their problems which was very welcome and did result in the early days of the inspectorate in a tremendous reduction of pollution. But, says the report, times have changed and this attitude may not be quite so effective nowadays and is in fact blocking the way to a more effective control of pollution.

"We like to help industry", Mr Ireland told the author of the report, "when we visit a works they are actually glad to see us." But from the outside, local authorities and members of the general public have made many complaints that the standards that the inspectorate itself lays down are often not being followed by the factories and that the inspectorate will allow works more than ample time to put their house in order even when this results in serious nuisance to local residents.

Local authorities which, through their own Public Health Inspectors, control pollution from all the factories and processes that are not registered under the Alkali Act, are one of the main critics of the Alkali Inspectorate. Some of the larger authorities have tried to break into the mutual admiration society obtaining between the inspectorate and the industries they monitor by suggesting that they should take over the inspectorate's duties, but this suggestion has been repulsed both by the inspectorate and by the industries themselves, who are seemingly unwilling to leave the inspectorate's protection.

Many of the complaints about inefficiency on the part of the inspectorate can be traced to its staffing which is described in the report as totally inadequate. Thirty-five inspectors monitor the 2,000-odd works registered under the Alkali Act and in these circumstances even the inspectorate admits it is unable to carry out the job as well as it would like.

The report concludes that despite its proud record and the undoubted technical expertise and determination of its staff, the Alkali Inspectorate is particularly ill-suited to the role now expected of it. It suggests that the simplest solution to the problem might be to transfer the responsibility for control of registered works to the local authorities, which nowadays have the technical skills needed to deal with this sort of work.

If the Alkali Inspectorate is to continue as an enforcement agency, then it needs more staff and more frequent inspections; but most of all, says Mr Fraenkel, it must be made accountable and all pollution data other than genuine industrial secrets must be published in a readily available form. The inspectorate's defence of its policy of non-publication is that the public does not understand pollution data.

Azbel's visa

WE have just received news that Professor David Azbel, one of the three Jewish intellectuals who went on hunger strike "taking a step befitting political prisoners" earlier this year (*Nature*, **248**, 2–3 (1974)) has received a visa permitting him to leave the Soviet Union. No visas have as yet been granted to his fellow strikers, Vitalii Rubin and Vladimir Galatskii.

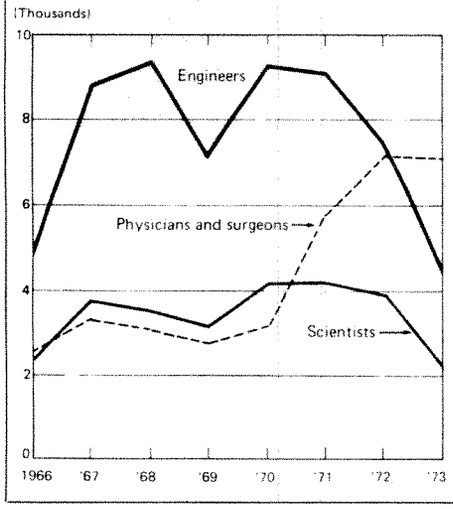
Happy birthday, Soviet style

Vera Rich

As readers will be aware by now, the 250th Anniversary Meeting of the Soviet Academy of Sciences has been postponed. A brief note in the *Pravda* of May 6, 1974 (which appeared on page 2, the page devoted to Party and political news) announced:

"The Academy of Sciences of the USSR with the approval of the Central Committee of the Communist Party of the Soviet Union has resolved to postpone the meeting devoted to the 250th anniversary of its foundation, from May, 1974, until a later date. During this time, celebratory (anniversary) meetings of the Academies of Science in the Union Republics will be held with the participation of Soviet society. Meetings devoted to the anniversary of the Academy of Sciences of the USSR, and to problems of the better implementation of scientific achievements in practice, will also be held in scientific institutions and establishments. It is intended that scientists will speak at industrial enterprises, collective farms and state farms with the aim of popularising scientific knowledge among the workers. The Academy of Sciences will complete its preparations and the publication of fundamental scientific works in honour of the anniversary, and will organise thematic exhibitions under the slogan, 'The Achievements of Science are for the National Economy'."

In these brief words, the preparations and expectations for a grand international celebration are 'postponed'—a word which may be taken in its literal sense, but which under the Stalin bureaucracy was a frequent euphemism for 'scrapped'.



There is of course a certain suggestion of unpreparedness here—that although the resolutions to celebrate the anniversary were published last autumn, the Academy is still in a state of unreadiness. In spite of the Soviet predilection for the fulfilment of norms ahead of schedule, such lack of preparedness for conferences has been known to occur.

Even if there has been some tardiness in preparation, however, this is not the full story, particularly as the date of the 'foundation' of the Academy can be interpreted in more than one way. What it was intended to celebrate this year was the issuing of a decree by Peter I ("the Great") establishing the Academy, on January 28, 1724. Having begotten the Academy, however, Peter died and the inaugural meeting took place nearly two years later, on December 27, 1725, in the presence of Peter's widow and successor Catherine I. On at least one occasion, the 1725 date has been celebrated as the anniversary; in 1945 a 220th jubilee celebration was held and, although under war conditions a 1944 celebration would have been impossible, there was nothing in the official publications about the occasion to suggest that this was in any sense a postponement.

Looking closer at the announcement, however, it is not merely a postponement; it is a change of aim and intention. Instead of a grand international gathering (which has been 'postponed'), there are concrete plans for lectures on the grass roots of Soviet society and a stress on scientific utilitarianism.

But would it have been an international meeting at all? Would the leading scientists of the world really

Brain drain reduced to trickle

THE huge influx of scientists and engineers into the United States during the late 1960s, which became popularly known as the 'brain drain', has been sharply curtailed by restrictive immigration regulations imposed by the United States Department of Labor. At the same time, however, physicians and surgeons are flocking to the New World in record numbers.

According to statistics published by the National Science Foundation, some 6,600 scientists and engineers entered the United States between July 1972 and June 1973—the first year in which the full force of the new regulations was felt. This compares with an annual influx of from 10,300 to 13,300 between 1967 and 1972. As for physicians and surgeons, 7,100 were admitted to the United States last year, more than twice the number corresponding in the late 1960s.

Designed to protect the jobs of American citizens against competition from cheap foreign labour, the new immigration regulations specify that an alien can work in the United States only if he has been offered a job which cannot be filled by a suitably qualified indigenous worker. Since there has been considerable unemployment among scientists and engineers stemming chiefly from cutbacks in expenditure on aerospace activities in the late 1960s, non-American citizens from those professions have a tough job getting round the regulations. By the same token, however, because there is a shortage of physicians and surgeons in the United States, qualified doctors are flooding into the country in increasing numbers.

The sharpest reduction in immigrant scientists and engineers between 1972 and 1973 was in the number of qualified Asians allowed to enter.

One sad irony is that scientists and engineers from India, for example, are being refused entry to the United States although there is massive unemployment among college graduates in India. At the same time, physicians and surgeons are flooding into the United States when they are badly needed in their home countries.

have gathered in Moscow to honour the Soviet Academy as a member of the international fraternity of science. With Academician Sakharov pilloried in the Soviet press as unworthy of the dignity of a Soviet scientist? With Jewish scientists who dare to apply for a visa for Israel submitted to all forms of harassment, from dismissal from their posts to petty and often puerile vexation, such as the ostentatious shadowing for no reason but to annoy? With an "opposition" seminar planned to be held in July in the Moscow apartment of one such dismissed scientist, Professor Aleksandr Voronel? With the British Royal College of Psychiatrists demanding in no uncertain terms last November an "impartial commission of enquiry by a broadly based group of psychiatrists of international repute, drawn from a number of countries", to investigate "the reports it has received about the alleged abuse of psychiatry in the management of individuals who take up a position of political dissent" in the Soviet Union?

In such circumstances, an international gathering might well prove too explosive a celebration. But the postponement announcement does not have the air of simply waiting for the tension to cool. The return to the grass roots, to the factories and farms, has the air of a total rethinking of how the event should be celebrated. If the outside world is critical of how the Soviet Union conducts its science, the Academy is willing to go out into the highways and byways and celebrate with the workers and peasants.

Start for UK on radiation

from our Solid State Physics Correspondent

BRITAIN had its first meeting on radiation effects in electronic devices on April 24—a one-day event organised by the Institute of Physics (IOP) at Imperial College, London. The meeting is notable mainly because of the general issues it raised. In the United States there has been an annual three-day meeting on this topic since 1964, the proceedings of which run to 250 pages but ten years later, the United Kingdom has had a mere one-day meeting with no published proceedings. The organiser, Mr K. J. S. Cave of the IOP Electronics Committee, termed the lag "regrettable".

Why are the levels of interest so disparate in the two countries and is this apparent lack of interest within the United Kingdom justified? In answer to the first question, the main difference could derive from differences in the size and philosophy of defence and space programmes in the two countries, rather than from differing extents of use of radiation sources for more mundane purposes (such as nuclear reactors, processing irradiators, ion implantation, radiography or basic research). A fair proportion of the physical investigations has been done in the course of producing 'radiation-hardened' semiconductor devices for the United States Department of Defense and, to a much lesser extent, for the National Aeronautics and Space Administration (NASA). The equivalent bodies in the United Kingdom government are not such expansive customers, although a few exploratory development contracts have been let by the Ministry of Defence. The difference here lies in the fact that United States strategic missiles must withstand nuclear attack, whereas the United Kingdom government has no such requirement. Space agencies in general seem to sponsor less work in this field in proportion to their need, partly because only a certain group of satellite trajectories intersect space radiation belts and perhaps the planners presume that they can avoid these—or fudge a solution.

As to the second question, the measure of justifiable interest for physicists should be the degree of understanding of physical processes which derives from the research. It is widely agreed that the physicist who studies the effect of radiation in an electronic device usually ends up by knowing more about that device than the man who designed it. Thus, we can say that the device physicist should gain benefit from such studies. Furthermore, it is common that investigators have to improve the general level of knowledge of radiation-induced defects in solids in order to formulate improvements in the 'radiation hardness' of a device. Thus, the phycist with an interest in the defect state of solids should find such work a suitable challenge. Similar arguments can be developed for ceramics, metals, plastics and other bulk materials and it can be said that the return in basic

knowledge is rather higher than is usual for such tactical research. On this reasoning, scientists in the United Kingdom may be missing a few tricks by not doing more work on radiation effects on their own behalf.

The planners may also have missed a trick here. Developing a radiation-tolerant material or device takes a very long time. In several advanced technological developments, radiation damage may often provide the limit to the usefulness of system: examples of such systems are fusion reactors and unmanned space vehicles. To obtain true effectiveness in research on radiation effects, the lead time may need to be well over ten years and start long before engineering designs take shape. A surprising amount can be gained by research which prevents device designers from pursuing the goal of radiation resistance in the wrong way. The analogy with preventive medicine is, in fact, strong and probably again extends outside the field of intricate semiconductor devices, with which the meeting in question was concerned. Because there is not, as in the United States, a well developed 'radiation effects community', the need for both underlying and short term research in this speciality may not get pressed as strongly as it should in the United Kingdom—there is no one to give the whole picture to the top level technological planners. In fact, it is notable how the 'reactor people', the 'device people', the 'dosimetricians' and other specialists, who have a lot to gain from each other's experience, very rarely join forces either in conference or Whitehall corridor to express a common interest in two basic processes with which they are all concerned, namely displacement damage and ionisation effects. A happy exception to this is the case of the ion implantation specialists, whose techniques are useful both to reactor and device designers and whose meetings embrace both fields. This suggests that it is time for a professional body to sprout a committee which does the job of bringing together specialists.

correspondence

Referees in print

SIR,—I read the recent letter by H. Fraenkel-Conrat [*Nature*, March 1] concerning anonymity of scientific reviewers with some interest.

I wonder if many readers are acquainted with the compromise system currently being used by the *Journal of Geophysical Research (Space Physics)*, and instituted by my predecessor, W. I. Axford. Each manuscript sent out for review is accompanied by a form stating that the journal acknowledges the assistance of reviewers by naming them at the end of the paper when it finally appears in print. The reviewers are asked to indicate on the form whether they agree to being acknowledged. If they agree, the paper appears with a footnote that states: "The Editor thanks A. Smith and B. Jones for their assistance in evaluating this paper". If one of them does not agree, the statement reads: "The Editor thanks A. Smith and another referee for their assistance in evaluating this paper". If both disagree, of course, no footnote appears, but many such papers are rejected in any case.

This rather simple device has worked very well since its inception; more than 90% of our reviewers do agree to this form of acknowledgment. It not only provides some small tangible acknowledgment of the reviewer, but it also apparently reduces the incidence of irresponsible reviews that are written solely for "the joy of releasing adrenaline with anonymous impunity", as Fraenkel-Conrat describes one such effort.

To my knowledge, no other journal has yet adopted the system in spite of its demonstrated success and general acceptance among scientists in the field of space physics. It does carry with it certain corollaries that may not be acceptable to many editors—for instance, reviewers' reports must be transmitted to authors in a more or less unadulterated form, since it would hardly be fair to acknowledge a reviewer publicly for a report that had been translated and heavily doctored by the editor himself.

Yours faithfully,

GEORGE C. REID

Aeronomy Laboratory,
National Oceanic and Atmospheric Administration,
Boulder, Colorado 80302

Soviet scientists

SIR,—Professor Burhop states in *Nature*, April 12:

> " . . . In Western society too much concern for problems of peaceful coexistence, disarmament and the abolition of nuclear weapons is regarded as at best naive and at worst subversive. In Soviet society these things are highly regarded."

It is reassuring to think that the crowds assembled in Moscow's Red Square on May 1 and November 3 are there to protest against the parade of intercontinental missiles with nuclear warheads that we see in the news photographs. Their protest is made impressive by the fact that it is expressed as applause, which makes it more orderly.

Professor Burhop also says that Soviet scientists who wish to emigrate to Israel bear a resemblance to Oswald Mosley in 1939. This lacks verisimilitude. The British Fascisti (the BBF of Aldous Huxley's *Point Counterpoint*) did not try to *leave*, even though many people wished they would.

Yours faithfully,

THOMAS H. JUKES

University of California,
Berkeley, California 94720

Lead in petrol

SIR,—In the second paragraph of the article "Lead in the Environment" (*Nature*, April 5, 1974). the writer states that in 1972 about 90,000 tonnes of lead were added to petrol in the United Kingdom alone. No reference is made to the source of this information but you may wish to correct the figure quoted which is grossly in error.

The Associated Octel Co. Ltd is the sole manufacturer and supplier of lead anti-knock compounds in the United Kingdom. The total production of lead alkyl compounds in 1972 was 101,000 tonnes, 27,600 tonnes of which were supplied to refiners in the United Kingdom and Eire, the remainder being exported worldwide. Since the lead metal content of anti-knock compound is approximately 40% w/w, the total weight of lead supplied to refiners in the United Kingdom and Eire was therefore around 11,000 tonnes in 1972.

Yours faithfully,

R. G. AICKIN

The Associated Octel Co. Ltd,
London W1X 6DT

Our figure for United Kingdom lead additives in petrol should have been 9,000 tonnes. Its appearance as 90,000 tonnes was a printing error—Editor.

news and views

Selectivity of nature

THE rate of evolution, and the varieties of adaptation open to a population depend on the degree of genetic variation which exists within it. The problem of measuring this crucial parameter seemed to be resolved with the use of the electrophoretic mobility of enzymes as markers for different alleles. This technique was first used to assess allele frequencies and heterozygosity in *Drosophila pseudoobscura* (Hubby and Lewontin, *Genetics*, **54**, 577; 1966) and has since been applied to numerous other species from armadillos to thrips. The results obtained from these vastly different species have been quite consistent. Between 10% and 30% of the gene loci sampled in a species are polymorphic, and 5%–15% of those in an individual are heterozygous. This seemed to provide abundant genetic variation on which selective pressure could act, until Kimura (*Nature*, **317**, 624; 1968) proposed that the different alleles at a given locus produce the same phenotype, so that most of the genetic variation revealed by enzyme electrophoresis is probably selectively neutral.

In that case, there would be comparatively little genetic variation which could be affected by evolutionary processes other than genetic drift. Kimura's argument for neutral mutation is based on the substitution rates of alleles producing macromolecules as the α and β chains of haemoglobin and cytochrome *c*, which have been roughly constant through evolutionary time. That would be the result if genetic drift were acting on neutral alleles, but not if there were alleles at a selective advantage or disadvantage. Kimura has further argued that the variation in fitness necessary to maintain so much genetic variability by selection would represent a "genetic load" so great as to result in the extinction of the population.

But heritable variability in virtually all characters has been the foundation of Darwinian evolution, and finding it difficult to believe that much of the genetic variability does not manifest itself in phenotypic variation, population geneticists have challenged Kimura's hypothesis on a number of grounds. Most of the parameters (effective population size, selection coefficients, mutation rates, and so on) necessary for population genetics theory are, however, unknown. This has meant working from 'reasonable' values to explore the consequences of the theory and see if plausible conclusions are reached; and what seems reasonable to one worker may not seem so to another.

Some more recent challenges have adopted a new approach, questioning Kimura's theory on its internal consistency in explaining certain kinds of data. There are several levels of attack, all based on the idea that even though relevant parameters such as population size are unknown, they have the same values for different loci of a species or for different alleles at a locus. Although, therefore, it is impossible to determine the selection acting on a specific locus or allele, it is possible, in some cases, to determine that there is selection on some of a group of loci or on some alleles at a locus. These consistency arguments, when properly applied, have been able to show that selection is acting on at least some of the loci which can be studied with electrophoretic techniques.

For example, if genetic drift is the only factor affecting gene frequency, each locus should be affected in the same way, regardless of the breeding structure—that is the population size, migration and inbreeding patterns—which are always unknown for natural populations. By sampling from several populations, it is possible to compute for each locus an effective inbreeding coefficient, F, which is nearly 1 when genetic drift is weak and nearly 0 when genetic drift is very strong. The observed F values for different loci can then be compared to find whether they are too heterogenous to be consistent with neutral mutation theory. This procedure was first suggested by Cavalli-Sforza (*Proc. R. Soc.*, **B164**, 362; 1966) with data from human blood groups and later used by Lewontin and Krakauer (*Genetics*, **47**, 175; 1973) on the fly *Dacus*. The most complete study of this type is that of Nevo (*Nature*, **244**, 575; 1973), who sampled thirty-one loci in eleven populations of *Theomomys talalpoides* (a pocket gopher). He argues that his discovery of F values ranging between 0 and 0.8 reveals too much heterogeneity to be consistent with neutral mutation theory.

Another approach, introduced by Johnson (*Nature*, **237**, 170; 1972) and analysed in detail by Johnson and Feldman (*Theor. pop. Biol.*, **4**, 209; 1973) is based on the evenness of the distribution of allele frequencies at different loci. If all of a given number of alleles at one locus are assumed to be neutral, then their frequencies are not expected to be either too similar or dissimilar. Each locus with a given number of alleles is an independent trial. Johnson and Feldman analyse previously published data on several *Drosophila* species and show that the frequencies are too even to be consistent with the neutral mutation theory. As with the distributions of inbreeding coefficients, one cannot determine which of the alleles are selected but only that there must be some factors, other than mutation and genetic drift which are affecting the gene frequencies.

Measures of the similarity of allele frequencies in different geographic regions forced Bulmer to the same conclusion (*Nature*, **241**, 199; 1973). Bulmer claimed that geographically separated natural populations of *Drosophila* are too similar in genetic composition for genetic drift, alone, to be acting. Maruyama and Kimura (*Nature*, **249**, 30; 1974) point out that Bulmer's argument depends on a theory which assumes implicitly that there are an infinite number of subpopulations and hence an infinite number of individuals in the species. Although mathematically correct, Bulmer's application was inappropriate. Maruyama and Kimura apply the theory of genetic drift in a finite number of subpopulations, first worked out by Maruyama (*Genetics*, **69**, 377; 1972), and conclude that the data are, in fact, consistent with the neutral theory. Although Maruyama and Kimura are forced to assume 'reasonable' values for several unknown parameters, they do show that, contrary to Bulmer's conclusion, the existing data on geographic variation are not inconsistent with the neutral theory. They also show, surprisingly, that even a very small amount of migration between subpopulations can maintain genetic uniformity in unselected loci over very large distances, on the same scale as the total range of the species. The next logical step will be to examine geographic variation in a single species in the light of Maruyama's theory in order to distinguish the selected from the neutral loci.

The recent challenges to the neutral mutation theory indicate a maturation of population genetics theory. Much of

the previous work in the subject has been directed to what might happen in natural populations in different sets of hypothetical circumstances. The apparent goal was to show that Darwinian evolution could be accounted for by changes in gene frequencies. Much of the recent theory takes that for granted and is motivated by and directed to observations of gene frequencies in natural populations. The neutral mutation hypothesis of Kimura has been one focus of such efforts. Although the studies of Nevo and Johnson show that some selection must be acting, their tone indicates the extent to which the neutral theory has been accepted. The question is no longer whether all of the genetic variation is selected or not but what fraction is selected. The recent work has shown that a significant fraction is selected, but it would be difficult to argue that the fraction approaches one.

How special is the Universe?

AN examination of the delicacy of advanced life forms and the requirement of highly special conditions for their existence would seem to support the long-standing tradition that the Universe has been created in a singularly convenient form for the presence of intelligent life.

It is truly remarkable that modern theoretical physics can make a contribution to this philosophical question. For example, it is sometimes pointed out how various naturally occurring numbers must be restricted in their values in order to be consistent with the existence of living matter. Dyson has remarked (*Scient. Am.*, **225**, 51-59; 1971) that an increase in the coupling constant of the strong interaction by only a few percent would have resulted in a catastrophic synthesis of most of the hydrogen in the Universe during the early stages of the big-bang, thereby depriving stable stars such as the Sun of their energy source, making life seemingly impossible. Another important naturally occurring number is the ratio between the electrical and gravitational forces between an electron and a proton (a staggering 10^{39}). Strangely, this number coincides with the age of the Universe measured in atomic units of time. Carter has argued (unpublished work) that this coincidence is necessary for the existence of intelligent life, on the basis that the lifetime of stable stars depends on the first number, and that this must be somewhere near the time required for intelligent life to evolve, which is of course just equal to the present age of the Universe. Thus the approximate equality of the two numbers is not a coincidence, but a direct result of our own existence.

The application of this philosophy to the initial state of the Universe rather than to the values of the constants of nature has been made by Collins and Hawking (*Astrophys. J.*, **180**, 317–334; 1973) who addressed themselves to one of the outstanding mysteries of modern cosmology. Why, out of all the possible distributions of matter, are we living in a Universe in which this distribution is so accurately isotropic? For it is a remarkable fact that whichever direction we look, the 3 K background radiation has the same intensity to one part in 1,000. This fact is all the more puzzling when it is realised that such widely separated regions of the Universe cannot have even been casually connected when this radiation was emitted, owing to the existence of a so-called particle horizon across which no information can pass. Collins and Hawking have pointed out, however, that although the Universe appears isotropic now, it need not always have been so. Restricting their discussion to homogeneous cosmological models, they show that there is a class of cosmologies which become isotropic as they expand from the initial big-bang. The most relevant discovery of their work is that the set of initial states of the Universe for this to happen is of measure zero in the set of all possible initial conditions. In layman's language, there can be no deviation at all from these special initial states if the Universe is to become isotropic. Moreover, it is just this same class of cosmological models which permits the growth of galaxies and stars by ordinary gravitational condensation, and hence permits the existence of life. So Collins and Hawking conjecture that man's own existence is a consequence of the isotropy of the Universe (see *Nature*, **242**, 304; 1973).

It must not be supposed that the adoption of the philosophy that the existence of life imposes severe constraints on the structure of the Universe implies a 'purpose-built' world with man as the end product. Most subscribers to the former viewpoint prefer to conjecture that there is not just one single Universe, but a whole ensemble, all with widely varying properties. In most of these universes life would be impossible because the very restrictive conditions would not be met. But, in some like our own, intelligent life is able to evolve and become conscious of its surroundings—in a nutshell, the world we live in is the world we live in. In answer to the question—where are these other universes?—we have two choices. Wheeler has suggested that our own Universe may not continue to expand forever, but may be returned eventually to a very dense condition where it will be 'reprocessed' and emerge into another cycle of expansion and recontraction. These cycles are supposed to continue indefinitely, passing through an infinite variety of structure and conditions with the 'constants' of nature, and perhaps even the laws of physics changing from one cycle to the next. Only very rarely does a cycle permit conscious organisms to evolve. Another possibility has been suggested by Everett in his interpretation of the laws of quantum mechanics. It is well known that quantum theory cannot predict precisely the outcome of any realistic experiment, but at best can only give the relative probabilities of the various possible outcomes. Conventionally, it is supposed that the real world selects from all the choices one particular result at random, but Everett has developed a theory in which all possible quantum alternatives presented are in fact realised, by the entire world splitting continuously into a stupendous number of 'parallel worlds'. Once again, only a small subset of such worlds would permit the existence of life.

Curiously enough, this 'bioselection' philosophy is usually accredited to modern cosmologists such as Dicke, Carter and Wheeler. In fact it was also used as long ago as the last century by Boltzmann in an attempt to explain why the Universe was in such a very remarkable state, rather than the much more probable condition of thermodynamic equilibrium. Boltzmann proposed that the Universe indeed spent nearly all its time in equilibrium, but on exceedingly rare occasions produced a vast fluctuation from equilibrium, thereby explaining its present (unstable) condition. The reason why we happen to be here to observe this extraordinarily unlikely occurrence because it is itself a necessary precondition for life, which requires continual thermodynamic disequilibrium for its existence. Boltzmann's fluctuations, like Wheeler's cycles, were supposed to occur repeatedly, though only after enormous durations.

Popular though this bizarre philosophy may be, there exists a counter philosophy the proponents of which are no less distinguished. According to this latter point of view, the Universe is not at all a remarkable place, but the almost inevitable outcome of a very wide range of initial conditions. Thus, for example, it has been claimed that there are various dissipative effects which would be present in the early Universe, and have the effect of damping out any anisotropies which may have been present initially, thereby leading to the high degree of isotropy now observed. In particular, Misner has examined the effects of neutrino viscosity, and recent exciting work by Zel'dovich and Starobinskii in the Soviet Union has shown that the tidal

gravitational effects present in an initially anisotropic Universe would give rise to creation of particle pairs out of the vacuum. The back reaction of this particle production on the evolving Universe is such as to remove some of the isotropy. Whether or not processes like these can really explain the isotropy of the Universe is not yet known, and it is in any case hard to see how sufficient damping could work for any initial conditions.

The most recent contribution to this fascinating debate is published by Bonnor in the latest *Monthly Notices of the Royal Astronomical Society* (**167**, 55–61; 1974). One of the restrictions of the Collins–Hawking result was that they treated only homogeneous cosmological models, on the supposition that any inhomogeneity would be expected to impede rather than assist the growth of isotropy. Bonnor claims, however, that this supposition may be unfounded. By removing the assumption of homogeneity and investigating the evolution of cosmological models which are initially inhomogeneous, he finds that under a wide range of initial conditions these models eventually approach both homogeneity and isotropy, that is, the Robertson-Walker type universes. Unfortunately, it is not clear from Bonnor's work just how general this result is, for his model is also restricted by being spherically symmetric about a privileged point in space, and therefore does not obey the usual cosmological principle.

The significance of Bonnor's result for the philosophical debate is that our present isotropic Universe may well have evolved from one of a wide variety of initial states of varying inhomogeneity, rather than from the exactly determined class of Collins–Hawking models. Whatever the outcome of this continuing debate, it is bound to have an influence on the way in which man relates himself to the Universe.

P. C. W. DAVIES

Changing views of the Moon's magnetism

BEFORE 1959 there was no direct way of telling whether the Moon possesses a magnetic field or not. But in that year prospects for the experimental determination of any possible lunar field improved markedly when Luna 2 took a magnetometer down to within 55 km of the Moon's surface. No field was actually observed, which, taking into account the sensitivity of the magnetometer, put an upper limit of 6×10^{21} gauss cm^3 on the Moon's global magnetic moment—a maximum value some four orders of magnitude lower than the present dipole moment of the Earth. This apparent lack of any significant global magnetic field on the Moon was confirmed a few years later by Luna 10, and again in 1967 by Explorer 35 which enabled the maximum moment for a dipole aligned along the lunar axis to be reduced to 6×10^{20} gauss cm^3 (Ness *et al.*, *J. geophys. Res.*, **72**, 5769; 1967 and **73**, 3421; 1968). A more detailed analysis of the Explorer 35 data, carried out a little later by Behannon (*J. geophys. Res.*, **73**, 7257; 1968), yielded a still lower value of 1×10^{20} gauss cm^3, and the most recent estimate of the maximum lunar dipole moment (based on Apollo subsatellite magnetometer results) is 6×10^{19} gauss cm^3.

Thus for more than a decade from the first attempt to determine the lunar magnetic field directly, most (but not quite all) indications were that the Moon is magnetically inert—a result entirely in accord with preconceived ideas about the nature of magnetism in planetary bodies in general and about the nature of the Moon in particular. Because the only viable theory for the origin of the Earth's highly variable magnetic field involves dynamo action in the molten core, it seemed natural to consider extraterrestrial bodies in similar terms. In other words, the absence of a global field on the Moon was seen as the result of the lack of any dynamo process in the lunar interior; and the absence of a lunar dynamo was to be expected, partly because the existence of molten metallic core of appreciable size seems to be precluded and partly because the Moon's rate of rotation is low. So few people were surprised at the inability to detect a lunar global field. It is true that before the end of the 1960s some of the Explorer 35 data had also been interpreted as indicating the existence of small scale (10–100 km) magnetic anomalies on the Moon, mainly in the highlands. But although the presence of anomalies has since been confirmed, the original interpretation was indirect and attracted comparatively little attention. It is thus historically quite correct to suggest, as Fuller (*Rev. Geophys. Space Phys.*, **12**, 23; 1974) does in his excellent review of the subject, that before the Apollo programme the Moon was generally regarded as 'magnetically uninteresting'.

Against this background of assumption and self-consistency, it apparently came as quite a shock to many geophysicists to discover that some of the returned Apollo 11 samples contained stable natural remanent magnetisations (NRMs) acquired before leaving the Moon—a discovery repeated with samples from subsequent Apollo missions. Moreover, magnetometers landed on the Moon by Apollo 12 onwards recorded surface magnetic fields in magnitude from about a gamma to hundreds of gammas; and there can be no doubt that these fields arise from the magnetisations of rocks in the lunar surface. Understandably enough, there was again a tendency to see these new and unexpected results in terms of processes comparable to those occurring on Earth. Thus for one thing it seemed reasonable to suppose that the NRMs in at least the lunar igneous rocks were thermoremanent magnetisations (TRMs) acquired as the rocks cooled through their Curie points. Since the time span by the magnetic lunar rocks represents at least several hundred million years, the implication then is that the magnetising field must also have lasted that long; and the field source most compatible with a long-term existence is, of course, the dynamo. In other words, although the Moon now has a dipole moment, if any, of less than about 10^{20} gauss cm^3 and apparently does not support a dynamo, for an extended period over 3,000 million years ago it must have acted as a dynamo giving rise to a dipole moment much greater than 10^{20} gauss cm^3.

Clearly this chain of argument contains its own inbuilt assumptions, the most obvious of which is that during its early history the Moon must have possessed a molten core with properties compatible with dynamo action. Presumably the lunar interior then cooled or the Moon's rate of rotation decreased, or both, so that at some time during the past 3,000 million years or so the dynamo ceased. All this is quite possible, although as Strangway and Sharpe point out on page 227 of this issue of *Nature*, as a theory it is rapidly going out of fashion in favour of one involving a Moon which accreted cold and subsequently heated up. This rules out an early lunar dynamo, but as Runcorn and Urey (*Science*, **180**, 636; 1973) noted last year, opens up the possibility, long rejected in the case of the Earth, of a magnetising field derived from permanent magnetism. In other words, although rocks such as the mare basalts would still have acquired their magnetisations thermally, they would have done so not in a field of dynamo origin but in the field from a 'permanently' magnetic lunar interior. As this permanent magnetism evidently does not exist now, it was presumably destroyed thermally as the Moon gradually heated.

By what process and in what type of field the permanent magnetism itself formed are not known. There is no shortage of fields suitable in principle (a much stronger solar field, a much stronger solar wind field, or the terrestrial field when the Moon was much closer to the Earth, for example), although it is difficult to see how the one which actually

magnetised the Moon can ever be identified. As far as the lunar magnetisation process is concerned, Runcorn and Urey rejected TRM because the required sequence of temperature changes is difficult to envisage and rejected viscous magnetisation because of its fundamental instability. Instead, they favoured depositional magnetisation involving magnetised particles settling nonturbulently through the accreting gas sphere in the external magnetic field, a process consistent with the existence of low temperatures. In this issue of *Nature*, Strangway and Sharpe now investigate a fourth possibility—isothermal magnetism acquired in a steady external field—in the light of the Moon's thermal evolution.

PETER J. SMITH

Dimensions of the possible

David Davies

THE "Recognition of Alien Life", a symposium organised by N. W. Pirie (Rothamsted Experimental Station) at the Royal Society on May 2, could as well have been called the Carl Sagan Symposium. Sagan—from Cornell University—jetted in to London, talked to the press, gave the first lecture, was never far from other speakers' minds for the rest of the day, interjected wittily, moved on to lecture elsewhere and jetted out. And with good cause was he at the centre, for nobody can have thought more than he about life elsewhere.

Alien life may be intelligent or not; Sagan considered the intelligent sort. At present, he said, nothing is known about extraterrestrial intelligence, but the technology is now available for the analysis of signals from stars and the scanning of planetary surfaces. Critical experiments, in his view, are coming up soon. The best data with which to start are observations of the Earth such as, say, Martians could make (not that Sagan has much time for Martian intelligence). All depends on resolution, as a collection of satellite photographs show. At 1 km resolution he could find no sign of life on Earth—except at Cochran, Ontario! True, cities appear as dirty smudges, but they show no sign of reworking. A useful guide is 'departure from thermodynamic equilibrium' such as is shown by geometrisation of Earth features. At 100 m resolution, this begins to show up in, for instance, large field patterns. The nocturnal light of cities is obvious, but an observer would have doubts, as many large cities are on waterfronts; maybe some chemical process could generate the light.

Eavesdroppers at stellar distances off radio emissions from Earth would be struck by the enormous energy density around metre wavelengths from radio, radar and television. These signals would be detectable at tens of light years and intelligent terrestrial life would rapidly be inferred from their highly ordered nature. With radio telescopes the range could be a thousand times greater, though given limited facilities, it is better, Sagan believes, to receive than transmit as man is likely to be the backward partner. The art of anticryptography—devising self evident messages for other intelligent life—is growing.

C. H. Waddington (University of Edinburgh) also considered intelligent alien life in trying to pin down what tells human beings that an artefact is just that. Unless one stumbles across a mechanical device, it is probable that repetition of shapes is as good a guide as any to intelligence. P. H. Gregory (Rothamsted) stressed that in talking about the recognition of life at the microscopic level the decision is largely an aesthetic one; on Earth man is still inadequately aware of the realms of possibility. He proposed an atlas of terrestrial microscopic objects as a valuable step towards improving methodology.

At this stage the meeting became philosophical as the discussion circled inconclusively round the question from the floor, "What is life?", reminding me of Gluck, my neighbour of Shelley and Sir Peter Medawar of flogging a dead horse.

The next contribution, by J. E. Lovelock (University of Reading), was in many ways the most fascinating. What could astronomical observations reveal about the probable existence of a biosphere? Thermodynamic disequilibrium in the atmosphere could be a good guide to the existence of life, and on Earth gross departures from equilibrium in nitrogen, hydrogen and methane point to life being present, a conclusion which multiplex spectrometry does not endorse for other planets.

The remainder of the meeting was devoted to questions of life on Earth, its past record, its energy relationships and its evolution. I. R. Kaplan (University of California, Los Angeles) reviewed stable isotope analysis, particularly of hydrogen, carbon, oxygen, nitrogen and sulphur. Variations in concentration ratios by biological enrichment are helpful in understanding past terrestrial environments. This scheme was taken further by P. C. Sylvester-Bradley (University of Leicester) for the Precambrian geological record. The origin of life is placed at about 4,000 million years ago (a review of this field appeared in *Nature*, **248**, 730; 1974). J. De Ley (State University, Gent) discussed energy sources and storage and remarked on the adenine-based nature of life on Earth through the dominance of ATP as an energy carrier. Finally, A. G. Cairns-Smith (University of Glasgow) speculated on the role of clays as possible catalysts or frameworks for the evolution of biochemicals from inorganic origins.

Medawar summed up characteristically: "The heterogeneity of life and the varieties of metabolism and modes of behaviour are so enormous that nothing should surprise us about alien life. All we can do is attempt to sketch out the dimensions of the possible".

Alloy glasses and beyond

from a Correspondent

AT the eighth International Thin Films Conference held at the University of Sussex from April 8 to 10 under the sponsorship of the Thin Films and Surfaces group of the Institute of Physics, the most noticeable feature was the diversity of topics discussed: many of the phenomena of solid state physics have now been reproduced in thin film form, and for good measure some novel phenomena have been discovered.

The growth in the technology of electron-optical instruments continues to provide new and valuable aids to the structural investigation of thin films. According to M. Prutton (University of York), it seems that the scanning Auger spectroscope may soon become a viable research tool, and already it can be used to analyse the composition of a 10 Å-thick surface layer. In the scanning mode of operation, simultaneous composition analyses can be obtained from a large number of positions on the surface of a given specimen.

J. G. Wright and P. K. Leung (University of East Anglia) used *in situ* electron diffraction methods to observe thin films of amorphous Co, Fe, Mn and Cr prepared by evaporation under ultra-high vacuum onto a substrate at 4 K. This work should provide final confirmation that amorphous metallic films are not caused simply by impurities in vacuum systems. In a similar vein, B. Cantor and R. W. Cahn (University of Sussex) described the structures of highly extended solid solutions in binary metal alloy films.

A large section of the conference was devoted to various electrical and magnetic properties of thin films. C. H. L. Goodman (Standard Telephone Laboratories, Harlow) pointed out that previous claims that chalcogenide and metal oxide glasses represent the biggest breakthrough since the transistor

are exaggerated, and he was not very confident of their potential usefulness except in relatively limited areas such as addressed display systems. In a stimulating paper, N. Boonthanom and M. White (Brighton Polytechnic) described the co-evaporation of metal/polymer mixtures to form a structure of conducting metal islands in an insulating polymer matrix. In these films teh resistivity changes by seven orders of magnitude over a temperature range of only 200 K.

The final session was concerned with the problems of fabricating magnetic bubble materials. It is a sign of the rate of progress in thin film physics that in such a recent development, the fundamental physics is already well established and the current problems are technological in nature.

More muonless neutrino events

from a Correspondent

LAST year the users of the European bubble chamber Gargamelle, at CERN Geneva, reported that they had observed neutrino interactions without outgoing muon tracks (*Phys. Lett.*, **46B**, 138; 1973; see also *Nature* **245**, 119; 1973). The simplest explanation for these events is that the weak interaction has a 'neutral current' component. If the effect is genuine then the implications are profound. The existence of a neutral weak current makes it possible to construct a rigorous theory combining both the weak and the electromagnetic interactions. Such theories have been proposed by Weinberg (*Phys. Rev.*, **D5**, 1412; 1972), and others.

When the Gargamelle result was announced there were unofficial reports that an American group had seen similar events in an experiment at the National Accelerator Laboratory (NAL) near Chicago. Now, after almost a year of careful checking, these data have been published (Benvenuti *et al.*, *Phys. Rev. Lett.*, **32**, 800; 1974) by a combined team from Harvard, University of Pennsylvania, Wisconsin and NAL. The groups used scintillation-counter and spark-chamber techniques to detect the events, to measure the energy of the reaction products and to identify muon tracks. Their neutrinos were produced from primary proton beams of 300 and 400 GeV, much higher than the 30 GeV energy of the CERN proton beam.

The team saw 76 events which must have been caused by neutrino interactions, but did not have a muon track: 93 neutrino events were seen with an identification muon. A number of different techniques have been used to calculate how many muon events had been wrongly identified, in particular, how many muons missed the muon detector. All versions of this calculation fail to account for the whole of the observed signal of muonless events. About 36 genuine muonless events remain, giving a corected ratio of muonless events to muon events of 0.23 ± 0.09.

Since this ratio is almost the same as that seen by Gargamelle, even though the detection technique is totally different and the beam energies are ten times larger, there can now be no doubt that muonless neutrino events do occur. Whether they are caused by a neutral weak current is not yet completely certain, but other explanations are becoming increasingly implausible.

Nutrient supply and ecosystem growth

from Peter D. Moore,
Plant Ecology Correspondent

THE term 'oceanicity' traditionally has conveyed to ecologists the impression of a climate with a low amplitude fluctuation in seasonal temperature and a high annual precipitation. There is now evidence, however, that other aspects of maritime environments—for example, nutrient cycling—may be of equal or greater ecological importance.

Nutrient elements in terrestrial ecosystems are cycled constantly between non-living and living components. There are gains and losses: gaseous elements are gained and lost through atmospheric movements; non-gaseous elements enter terrestrial ecosystems largely by means of the weathering of rock particles in the soil or as solutions or particulate fragments from the atmosphere, arriving as aerosol or dust. In some rather exceptional types of ecosystem other transport mechanisms may be important, such as inwash of detritus by rivers or sea, or the immigration of animals to roost, nest or defaecate. Non-gaseous nutrient elements are lost from ecosystems largely as a result of soil leaching (see Bormann and Likens, *Science*, **155**, 424; 1967).

In a stable, climax ecosystem nutrient gains are balanced by nutrient losses, whereas in seral ecosystems, still developing, gains exceed losses. The excess of gain over loss is normally associated with an increase in biomass. The final constraint which limits ecosystem development, however, is normally a climatic one rather than nutrient availability, although in some climax ecosystems (for example, ombrotrophic mires) nutrients may be limiting (Firbas, *Veröff. geobot. Inst. Zurich*, **25**, 177; 1952). It is possible, within the general climatic restrictions, that availability of nutrients in an ecosystem could influence the rate at which succession takes place and equilibrium is attained.

In the light of this knowledge of nutrient cycling in ecosystems, it is rather surprising that nobody has yet attempted to measure the rates of successions in maritime regions where aerial nutrient input can be expected to be high and to compare these with areas of similar edaphic and climatic qualities far removed from the sea. Art, Bormann, Voigt and Woodwell (*Science*, **184**, 60; 1974) have now produced data from a maritime climax forest ecosystem which makes such a comparison even more imperative.

Fire Island, the research site, is a barrier island off Long Island, New York. It is fringed by sand dunes and salt marshes and contains a forest ecosystem in the lea of mature dunes. Art and his colleagues have attempted to determine the source of incoming nutrients to this forest and, by a process of elimination, they have come to the conclusion that aerosols and airborne particles constitute most of the nutrient input. They consider weathering an unimportant source of nutrients because the substrate is 98% quartz sand and the remainder (magnetite, garnet and tourmaline) is also unlikely to be a major source of ions. Animal inputs, mainly seabird guano, are only locally important and are of no significance within the study area. The soaking of seawater into the ecosystem from below does not occur because of the peculiar hydrology of the island; a high precipitation: evaporation ratio leads to a downward movement of freshwater to a depth of about 40 m below sea level in the centre of the island, thus excluding salt water. There remains the income from airborne sources.

Art *et al.* divide the airborne material into three types—a rain component (collected in rain gauges open only during rain), a dry fallout component (from gauges open all the time, less the rain component) and an impaction component (by measuring the difference between above canopy and below canopy composition of rainfall and determining the excess beneath canopy). Total annual figures of meteorological input obtained were (in g m^{-2}): 0.73 K; 14.15 Na; 0.98 Ca; and 1.91 Mg. These figures compare very closely with those obtained in other oceanic situations; for example, the Shetland Isles (see

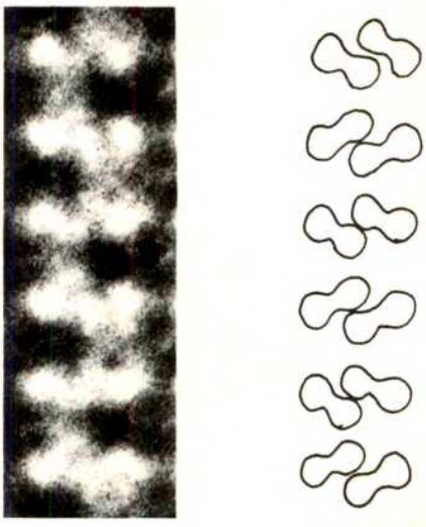
Gore, *J. Ecol.*, **56**, 483; 1968) 0.55 K; 13.3 Na; 0.67 Ca; and 1.92 Mg and on the Lizard Peninsula in Cornwall (Malloch, *J. Ecol.*, **60**, 103; 1972) 3.8 K; 19.8 Na; 0.9 Ca; and 2.0 Mg.

The annual uptake of nutrients by the vegetation of the Fire Island forest was determined by measuring the nutrient content of the net primary production in midsummer. The loss of nutrients by litterfall and canopy leaching was found to balance this uptake for most elements, and it would thus seem that the forest is in a climax, equilibrium state. The limitations upon growth in this ecosystem seem to be quite complex. Increased nutrient input would, theoretically, result from a larger tree canopy (that is, greater above-ground-biomass) because this would enhance the impaction component, but this is made impossible by the destruction of emergent shoots by high intensity, salt-laden winds. Vegetative proliferation is possible only by low-level lateral branches in the canopy and this seems now to have reached maximum development; as a result a climax has been attained.

In terms of biomass (17,000 g m^{-2}) and net primary productivity (1,100 g m^{-2}) the Fire Island forest compares well with the figures for temperate forest collected by Rodin and Basilevich (in *Functioning of Terrestrial Ecosystems at the Primary Production Level* (edit. by Eckardt), Unesco, Paris, 1968). This is despite the extreme nutrient poverty of the sandy substrate. A comparison of nutrient input figures from the Fire Island forest with those from other forest ecosystems shows that the meteorological input alone of several important elements (for example, K and Ca) equals the total (meteorological plus weathering) input of these elements in forests further from the sea. Thus, if nutrient availability is arresting the succession, it is not surprising that the biomass of this 'subclimax' falls little short of that found in climatically limited forests.

Finally, to return to the relation between nutrient availability and the rate of successions, it is interesting to note that the Fire Island forest is considered, on the basis of radiocarbon dating and geological evidence (Sirkin, *Bull. Torrey bot. Club*, **94**, 131; 1972), to be only 200–300 years old. The dune systems around the inland lake Michigan are considered to have taken thousands of years to attain a forested state, but there the low nutrient availability from weathering is accompanied, one presumes, by a low aerial nutrient input. Much more data are needed from such inland dune systems in terms of their nutrient balance, but it seems that there is a strong case for supposing that overall nutrient availability is the factor controlling the rate of succession on those sand dunes. Such a knowledge will undoubtedly provide ammunition for those ecologists who consider that the limiting effects of nutrient supply upon the developmental rate of ecosystems is a general feature of successions (see *Nature*, **240**, 443; 1972).

Repressors at the molecular level



from Stephen Neidle

THE cluster of three genes responsible for lactose metabolism in *Escherichia coli* have been perhaps the most intensively studied of all bacterial chromosome systems. Indeed advances in knowledge of this cluster, known as the *lac* operon, have often tended to be hailed as landmarks in molecular genetics generally. It is now some 13 years since Jacob and Monod first proposed that the control of protein synthesis in bacteria involves certain agents that can repress the relevant genes, and hence inhibit specific messenger RNA synthesis. The first of these substances to be isolated and characterised was the lactose (*lac*) repressor, which is a tetrameric protein of molecular weight 150,000 (Gilbert and Müller-Hill, *Proc. natn. Acad. Sci. U.S.A.*, **56**, 1891; 1966). These workers followed this considerable technical achievement by demonstrating convincingly that the repressor does indeed act on the *lac* operator locus of a DNA molecule (*ibid.*, **58**, 2415; 1967).

Detailed knowledge of how repressor proteins turn off DNA at the molecular level, however, is still almost entirely lacking, although some interaction and control models have been proposed, notably by Sobell, Müller-Hill and Gierer. The amino-acid sequence of the *E. coli lac* repressor, as well as the nucleotide sequence of its target on the chromosome, the *lac* operator, have both been recently determined (*ibid.*, **70**, 3576; 1973). Thus, it is not altogether unexpected that protein crystallographers have begun to take an interest in repressor proteins, especially since modern techniques can now provide structural information about such large molecules. Steitz and his colleagues at Yale (*ibid.*, **71**, 593; 1974) have succeeded in crystallising the *lac* repressor, but have obtained disappointingly small microcrystals. Although these are not large enough for even preliminary single-crystal studies, they have revealed a measure of useful information. A combination of powder X-ray diffraction data and electron micrographs has given a good indication of the size and possible symmetry of the unit cell of the protein, as well as that of the tetrameric unit itself. There are four of these tetramers in each orthorhombic repeat, and they appear to be asymmetric and dumbbell in shape, with a length of about 135 Å. It seems most likely that the subunits of the repressor molecule are related by D_2 point-group symmetry, rather than the four-fold symmetry proposed by Sobell (*ibid.*, **69**, 2483; 1972).

This necessarily meagre amount of data has nonetheless enabled Steitz *et al.* to both reject several of the proposed repressor–DNA operator interaction models, and to suggest one of their own. Any such model has to take into account the two-fold symmetry regions found in the operator nucleotide sequence by Gilbert and Maxam. Rather than binding to either single stranded DNA or four-leaved cloverleaf DNA (both suggested arrangements for the operator locus), the new suggestion is that the dumbbell repressor binds in a manner such that its long axis and the double-helical polynucleotide axis are parallel. The arrangement is described as being similar to a "hotdog in a hotdog bun", which analogy is perhaps clearest to those most familiar with the finer points of the American cuisine. The model has, however, several attractive features, notably that it does not contravene accepted dogma regarding protein–substrate and protein–protein interaction. Also, it has two-fold symmetrical binding grooves, which comply rather well with the operator sequence data.

Until there are more detailed structural studies of both the repressor protein itself, and maybe even complexed with the *lac* operator fragment of the genome, there will doubtless be numerous more suggested models.

Steitz *et al.*'s enlargement of part of the translationally averaged election micrograph with, on the right, their interpretation of the molecular outline. Each dumbbell is one repressor tetramer and there are four tetramers per unit cell.

Roundtable on neuroendocrinology

from Barend ter Haar

DURING the weekend April 6-7 recent neuroendocrinological findings of most of the leading laboratories in Europe were discussed informally at Magdalen College, Oxford in an effort to establish the most fruitful course of future research, and to sow the seeds for greater international collaboration. The sessions were divided under the general headings of hypothalamic releasing hormones, secretion of the hormones of the posterior pituitary, monoamine systems affecting endocrine function, rhythms involved in neural control of reproductive function and processes involved in sexual differentiation and puberty.

It had been hoped that with the elucidation of the amino acid sequence of luteinising hormone releasing hormone (LHRH) and its subsequent chemical synthesis, antibodies prepared against this material could be used to identify, by immunofluorimetric techniques, the neurosecretory cells for LHRH in the brain. Though J. Barry (University of Lille) has been able to demonstrate a distribution of such neurones throughout certain areas of the anterior and medial hypothalamus of the guinea pig, he has as yet been relatively unsuccessful in other species: there is still much progress to be made in this field. It was noted with interest that Barry has also found labelled axons extending from the hypothalamus to the limbic system: it is now becoming more obvious that classical concepts of unidirectional flow of neuronal information from the limbic to the anterior hypothalamus and then to the median eminence have to be altered.

To add to the complexity, M. C. Harris (University of Birmingham) and G. B. Makara (Institute for Experimental Medicine, Budapest) indicated that they had also found not only cells in the arcuate nucleus and median eminence with axonal terminations in the anterior hypothalamus, but also hypothalamic cells which appeared to project both forwards, to the paraventricular nucleus, and also caudally, to the median eminence. Of further interest concerning efferents from the hypothalamus to other brain areas, and in the context of recent observations of effects of thyrotropin releasing hormone (TRH) on certain psychiatric disorders, were the observations presented by R. Dyer (University of Bristol) that both TRH and LHRH can modify electrical activity in the cerebral cortex in a similar way to their observations in the hypothalamus.

It is clear that though radioimmunoassay techniques have greatly helped to advance neuroendocrine knowledge, great care is still needed in the interpretation of results, the principal difficulty being that immunoreactive sites on a molecule do not necessarily relate to biologically active sites. Furthermore, such assay techniques are of little use in the detection of brief hormonal discharges such as the 2-second discharge of oxytocin demonstrated by D. W. Lincoln (University of Bristol) by means of transient changes in mammary pressure. For the release of posterior pituitary hormones, N. A. Thorn (University of Copenhagen) suggested a similar involvement of calcium in hormone discharge as in the mechanisms of muscle contraction.

In discussing the effect of circadian rhythms on reproductive function, B. K. Follett (University College of North Wales, Bangor) described how in the sparrow photosensitivity seems to vary in a circadian fashion in that a limited period of sensitivity occurs about 12 h after dawn. He has found that if light is present at this time reproductive activity is promoted so that sexual activity becomes linked with maximum day length. P. C. B. MacKinnon (University of Oxford) described how the circadian rhythm of cerebral protein metabolism in the rat is sexually differentiated, and put forward the hypothesis that the 'female' rhythm is involved in the synchronisation of internal and external signals to bring about reproductive activity in the most suitable conditions.

In considering the processes involved in the onset of puberty, F. Döcke (Humboldt University, Berlin) indicated that the limbic system is involved in controlling sexual development, and H. Moll (Erasmus University, Rotterdam) suggested that the search for only one control process may be misguided, and that puberty may be brought about by the coordinated maturation of several processes.

Obviously much more was discussed than there is space here to relate. The organisational efforts of B. T. Donovan (Institute of Psychiatry, London), C. Kordon (INSERM, Paris), and G. P. van Rees (University of Leiden) in getting together so many authorities on various branches of neuroendocrinology were well rewarded by the informal exchange of ideas that was achieved.

Correction

IN the News and Views article "Beyond systems ecology" (*Nature*, **248**, 637; 1974), the authorship of the two publications cited was misattributed. The article in *Proc. N.Y. Acad. Sci.* is by R. Levins, and the book *Stability and Complexity in Model Ecosystems* is by R. M. May.

Characterising the stringent system

from Benjamin Lewin
Molecular Genetics Correspondent

POSSIBLE relationships between protein synthesis and transcription have attracted attention for more than a decade, and in recent months this concentration of interest has been justified by results which may lead to the definition of the components of the stringent system of *Escherichia coli*. Genetic characterisation of this system has so far led to the isolation of two classes of mutant. As was first shown by Cashel and Gallant (*Nature*, **221**, 838; 1969) and Cashel (*J. biol. Chem.*, **244**, 3133; 1969) relaxed (*rel*$^-$) mutants do not restrain ribosomal RNA synthesis during starvation for required amino acids because (unlike the wild type stringent cells) they cannot increase their levels of the 'magic spot' compounds ppGpp and pppGpp in response to the deprivation. Cells of the spotless (*spoT*$^-$) mutant, isolated more recently by Laffler and Gallant (*Cell*, **1**, 27; 1974), cannot produce pppGpp during amino acid starvation, but overproduce ppGpp.

Although it is clear that accumulation of ppGpp and pppGpp is responsible for inhibiting RNA synthesis, the mechanism of formation and action of these two compounds has only more recently come under investigation. By following the abilities of *rel*$^+$ and *rel*$^-$ strains to form magic spots and respond to changes in growth conditions, Lazzarini, Cashel and Gallant (*J. biol. Chem.*, **246**, 4381; 1971) found that *rel*$^-$ cells, although unable to respond to amino acid starvation, show the same response as *rel*$^+$ cells to other changes, such as shifts in growth rate. The *rel* gene must therefore code for a protein implicated in forming ppGpp and pppGpp specifically in response to lack of amino acids, a reaction which has proved to be mediated by the consequent lack of aminoacyl-tRNA. By showing that the stability of ppGpp is much enhanced in *spotT*$^-$ cells, Stamminger and Lazzarini (*Cell*, **1**, 85; 1974) have come to the conclusion that the *spoT* gene product may be responsible for converting ppGpp to pppGpp. Clearly, many other genes may also be part of this system and the levels of the magic spots may be controlled at degradation as well as synthesis.

The concept originally suggested some time ago that an 'idling reaction' of protein synthesis may be responsible for formation of magic spots has recently been substantiated by the use of *in vitro* systems. Haseltine *et al.* (*Nature*, **238**, 381; 1972) found that ribosomes from stringent cells can synthesise ppGpp and pppGpp *in vitro*

from substrates of GTP and ATP; and ribosomes of relaxed cells are unable to perform this reaction, but can do so when extracts are supplemented with a 'stringent factor' extracted from wild type cells. Formation of the magic spot compounds takes place *in vitro* when the A site of the ribosome is occupied by an uncharged transfer RNA; this evidently acts as a signal to the ribosome that protein synthesis is limited and allows the cell to titrate its amount of uncharged tRNA.

The protein responsible for responding to the blocked A site has been studied by Ramagopal and Davis (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 820; 1974). Examining *rel*$^+$ ribosomes showed that the protein is easily extracted from them and so may be only loosely bound to the ribosome. Using an assay in which protein extracted from *rel*$^+$ ribosomes was measured for its ability to stimulate the reaction *in vitro* of unwashed *rel*$^-$ ribosomes (the lack of washing means that these ribosomes possess all other necessary components), Ramagopal and Davis found that 50S subunits, 70S ribosomes of polysomes, and 70S ribosomes which have runoff polysomes all possess *rel*$^+$ protein activity. The protein activity is not present on 30S subunits. These results suggest that the stringent factor is a ribosomal protein as such, rather than a factor which associates with the ribosome during only part of its protein synthetic cycle, and is a loosely bound component of the 50S subunit. Since it is present on both free and polysomal 70S ribosomes, these results cast no light on the conditions necessary for formation of magic spots. But they offer the prospect that further characterisation of the protein may allow both its stringent activity and also whatever other functions it may have to be defined.

Although both genetic analysis and biochemical characterisation of the stringent system suggest the outlines of its operation, many important questions remain to be answered. The first class concerns the formation of ppGpp and pppGpp. Clearly, they are formed on the ribosome in response to inhibition of protein synthesis by entry of uncharged tRNA to the A site. Although the exact mechanisms of this reaction remain to be elucidated, the *rel*$^+$ protein seems to mediate this response. One discrepancy which remains to be resolved is that ppGpp can be formed *in vitro* from GDP and ATP, whereas pppGpp can be synthesised from GTP and ATP; but *in vivo* the *spoT* gene product has been implicated in converting ppGpp to pppGpp. Another critical reaction, so far investigated scarcely at all, is how these components are formed in response to conditions other than amino acid starvation—isolation of mutants in these processes must provide an essential first step in analysis.

The second set of problems, which at the present seems more difficult to approach, concerns the reactions by which ppGpp and pppGpp mediate the inhibition of rRNA synthesis. One particularly interesting problem is why there are two magic spot compounds and what difference there may be in their functions. But attempts to show *in vitro* that ppGpp influences rRNA synthesis at the level of RNA polymerase activity have not so far proved very satisfactory. Yet the nature of this general coordinating system may prove to throw an important new light on the control of transcription in bacteria.

Control of 3T3 cell growth

from Brigid Hogan

THE mouse 3T3 line—so-called because it was derived from embryo cells transferred every 3 days at an inoculum of 3×10^5—since it was established in 1963 has been widely used in studies of the control of proliferation of mammalian cells in culture. As long as the strict transfer regime is maintained, the cells consistently show distinct growth properties. First, they are very sensitive to a reduction in serum concentration in the medium and divide about five times slower in 1% than in 10% serum. Second, even if the cells are regularly replenished with 10% serum medium, they only grow very slowly after reaching a monolayer density of about 5×10^4 cells per cm^2. Finally, they will not grow in suspension in agar or methylcellulose. It is, however, well established that 3T3 cells transformed by the oncogenic viruses SV40 or polyoma exhibit very different properties; they divide rapidly in 1% serum, reach far higher densities and form colonies in agar.

During the past few years Pollack's group in Cold Spring Harbor has been investigating the complex interrelation between these three parameters and the way in which they are modified by tumour viruses, by selecting sublines of SV3T3 which have reverted back to more normal behaviour. The first lines were selected for a reduction in growth at high cell density by exposing dense cultures to 5-fluorodeoxyuridine for 2 days so that cells synthesising DNA were killed. Clones which survived this treatment had a much more 'normal' morphology and were therefore called "flat" revertants, and reached a saturation density of only about 8×10^4 per cm^2, although the shutoff in division at this density is not as complete as in normal cells.

More recently similar 'density revertants' have been selected by killing growing cells with 5-bromodeoxyuridine or colchicine (Vogel *et al.*, *J. cell. Physiol.*, **82**, 181-188; 1974). When their other properties were tested, the density revertants fell into two classes; one which grew well in 1% serum and one which did not, but neither class would grow in agar. Using similar techniques Pollack's group have also selected 'serum revertants' which do not grow rapidly in low serum (Vogel and Pollack, *ibid.*, 189–198); these also show low saturation density but may or may not grow in suspension. Thus it has been possible to select variants of SV3T3 which have reverted in either of two, or in all three aspects of transformation. All classes of revertants have more chromosomes per cell than the parent, synthesise SV40 Ts antigen, and in some cases have been shown to contain intact virus genomes, so that their altered behaviour is likely to arise from a change in the expression of some cellular gene(s).

Pollack's group have not been slow to take advantage of the properties of their mutants to throw light on the role of cyclic AMP in the control of 3T3 cell proliferation (Oey *et al.*, *Proc. natn. Acad. Sci., USA.*, **71**, 694–698; 1974). In agreement with many other groups they found that sparse cultures of 3T3 in 10% serum contain twice as much intracellular cyclic AMP as SV3T3s. In the same conditions most revertant lines returned to having the higher levels of cyclic AMP characteristic of 3T3s, but two retained the low concentration found in SV3T3s. These two are the only revertants able to form colonies in methylcellulose so that there may be a correlation between low amounts of cyclic AMP and ability to grow in suspension. Only those revertants which are unable to grow in low serum share the property with 3T3s of rapidly and extensively increasing their concentrations of cyclic AMP when the serum concentration is reduced to 1%, and density revertants which can grow in low serum maintain the lower concentrations of cyclic AMP found in SV3T3s.

Finally, Oey *et al.* allowed normal 3T3s and two serum revertants to attain their low saturation density in conditions in which the 10% serum medium was regularly replaced, even after cell growth had slowed down. In all three lines they failed to find an increase in cyclic AMP as the cells reached their saturation densities. Taken together with the other findings, this suggests that density restriction and serum restriction of growth are not identical phenomena, as some workers have postulated, but are mediated by two different, but probably interrelated, mechanisms.

Radioactivity of tobacco trichomes and insoluble cigarette smoke particles

Edward A. Martell

National Center for Atmospheric Research, Boulder, Colorado 80302

Airborne ^{210}Pb is concentrated on small Aitken particles which accumulate on tobacco trichomes. Tobacco curing and the combustion of trichomes in burning cigarettes produce insoluble particles of high ^{210}Pb radioactivity which are inhaled and deposited in the bronchi of smokers. The subsequent ingrowth of ^{210}Po results in high local α irradiation which may account for bronchial cancer among smokers.

EXPOSURE to α radiation from the short-lived radon daughters, ^{218}Po and ^{214}Po, is generally considered the cause of bronchial cancer in uranium miners[1]. The presence of the α emitter ^{210}Po in the bronchi of smokers in excess of ^{210}Po levels of non-smokers[2,3] thus warrants serious consideration as the possible agent of bronchial cancer among smokers. Both ^{210}Pb and ^{210}Po have been observed in tobacco, in cigarette smoke and in smokers' lungs[2–7].

Radford and Hunt[4] pointed out that volatile ^{210}Po compounds are inhaled by smokers and suggested that ^{210}Po was bound strongly to the surfaces of smoke particles, thereby entering the bronchi. But, as Holtzman[8] and others pointed out, it is likely that the volatile compounds of ^{210}Po which are inhaled are widely dispersed and cleared rapidly from their deposition sites in the lung. Little *et al.*[2], however, found high local tissue concentrations of ^{210}Po corresponding to an estimated maximum dose of ~200 rem per 25 yr to the bronchial epithelium of lower-lobe bifurcations of cigarette smokers[3]. This can be explained by the accumulation of insoluble ^{210}Pb particles in the bronchial bifurcations. The ^{210}Pb activity of insoluble smoke particles is sufficiently high to give rise to α doses much higher than 200 rem per 25 yr in regions of high particle concentration.

^{210}Pb on tobacco trichomes

Reports on the origin and distribution of ^{210}Pb and ^{210}Po in tobacco plants are contradictory. Tso *et al.*[9], conclude that the principal mechanism involves uptake into roots from soils and fertilisers, whereas Francis *et al.*[10] suggest deposition in rainfall. The properties and distribution of trichomes (hairs) on tobacco leaf surfaces[11,12], however, suggest that they are effective collectors of small Aitken particles by means of diffusive deposition. Most commercial varieties of tobacco have 300 to 900 trichomes cm^{-2} on each side of mature leaves. The distribution of trichomes on cured tobacco is illustrated in Fig. 1. About 85% of tobacco trichomes have glandular heads, coated with a sticky exudate mixture of organic compounds. Because of the hydrophobic nature of this exudate it is unlikely that even soluble, ionic substances are washed off by precipitation. Thus, trichomes may retain the small atmospheric particles which are deposited on their glandular heads throughout the period of plant growth.

The thick distribution of trichomes maintains a stagnant air layer over the leaf surface with only the glandular heads of trichomes protruding. For the low air flow rates in the vicinity of trichome heads, the only effective mechanism for airborne particle capture is likely to be diffusive deposition due to Brownian motion of the particles. The efficiency of this process varies inversely with particle size and flow rate and thus may result in the selective deposition of particles of ~0.1 μm diameter and smaller. Radon daughters in air are concentrated on small Aitken particles[13,14]. Impactor measurements (my unpublished results for radon daughter aerosol properties, with H. E. Moore and S. E. Poet) show that ~90% of airborne ^{210}Pb resides on particles $\leq$0.3 μm diameter at concentrations between 2×10^3 and 10^4 pCi g^{-1}. The ^{210}Pb concentration increases markedly with decreasing particle size[14]. Thus Brownian capture should give rise to high ^{210}Pb concentrations on tobacco trichomes.

Preliminary measurements of ^{210}Pb on cured tobacco leaves by analysis of surface particles removed by brushing and by sonic cleaning, showed ^{210}Pb concentrations of leaf surfaces up to 30 times that of the bulk leaf per g ash. Microscopy showed that trichomes were only a minor constituent of this surface debris. Subsequently, 2,000 trichomes were removed from North Carolina flue-cured tobacco and assayed for ^{210}Po by α spectroscopy[15]. The average ^{210}Pb activity per trichome, based on this ^{210}Po measurement and the ^{210}Po:^{210}Pb ratio of the tobacco sample, was $(3.2 \pm 0.6) \times 10^{-6}$ pCi per trichome. Turkish tobacco and Kentucky burley showed ~1/2 and ~1/4 as much activity per trichome, respectively. These results indicate the accumulation and retention of tens of thousands of Aitken particles on individual trichomes, presumably on the exudate-coated glandular heads.

The solubility of separated trichomes from cured tobacco was examined. Although exudate is soluble in ether and other organic solvents before the tobacco is cured[12], the trichome heads for cured tobacco seem to be insoluble in ether, acetone and other common organic solvents as well as in concentrated HCl, HNO_3 and HCl-HNO_3 mixtures. This result is attributed to the polymerisation of exudate compounds during the curing period.

The trichomes and their glandular heads have an open, cellular structure of very low density. These properties are illustrated by the collapse of trichomes when subjected to high vacuum. ^{210}Pb activity on trichomes is probably largely associated with the exudate coatings of trichome heads. When a smoker draws on a burning cigarette, the trichomes on the tobacco fibre surfaces are subjected to temperatures from 650° C to more than 800° C[16]. The pyrolysis of glandular heads of trichomes at these high temperatures should yield smoke particles with specific activities of ^{210}Pb which approach or exceed an estimated 10^5 pCi g^{-1}.

^{210}Pb in smoke particles

Published radiochemical data for inhaled mainstream smoke show an average ^{210}Po content of ~0.036 pCi per cigarette or ~2.6 pCi ^{210} Po per g smoke[17], with a ^{210}Pb:^{210}Po ratio of 0.66 ± 0.23[6]. The smokers' intake of ^{210}Po and ^{210}Pb within several days is equivalent to the observed excess burden of 3–10 pCi of ^{210}Pb and ^{210}Po in smokers' lungs[6,7]. Thus most of

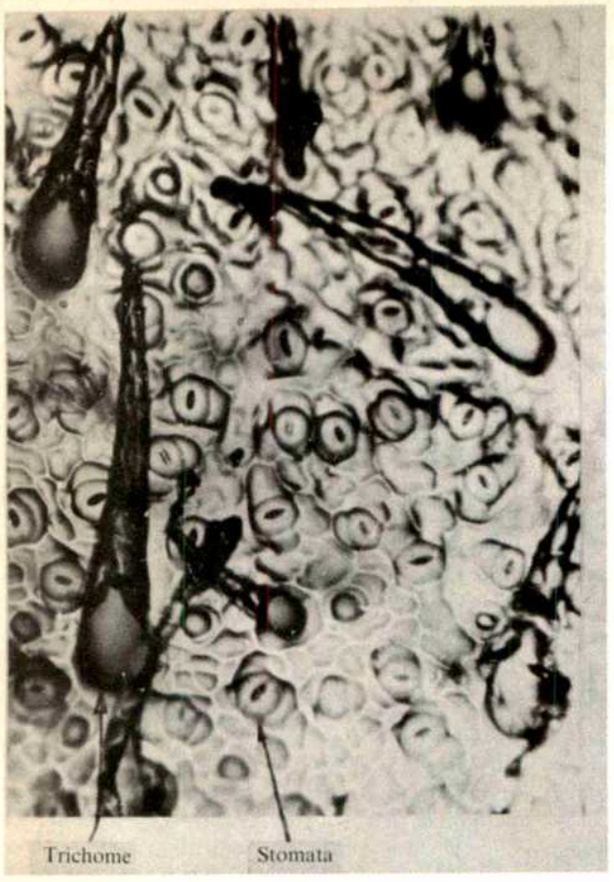


FIG. 1 Microphotograph of flue-cured tobacco, Hicks variety, bottom surface, showing trichome and stomata distribution (leaf section 550 μm × 835 μm).

the ^{210}Pb and ^{210}Po deposited in the smoker's lung must be cleared rapidly.

There is no published evidence about the physical and chemical properties of the ^{210}Pb content of insoluble smoke particles which may persist in the lung. To investigate this question, I used samples of whole condensate, prepared by standard techniques and procedures[18]. University of Kentucky 1R1 reference cigarettes (a non-filtered cigarette of standard US blended mixture) and Players cigarettes (all flue-cured tobacco) and large whole smoke condensate samples of each, were used.

Condensate samples were heated to drive off volatile constituents. The ^{210}Po was volatilised almost completely at temperatures between 600° C and 650° C, whereas all the ^{210}Pb remained in the residue, indicating that ^{210}Po is inhaled in volatile form and ^{210}Pb is associated with the particulate fraction of mainstream smoke.

Preliminary radiochemical results for 1R1 tobacco showed that the ^{210}Pb content was 0.40 pCi per g dry tobacco, 0.81 pCi per g of dry whole smoke condensate, and 130 pCi per g of the non-volatile residue after slow distillation of the volatiles up to 650° C. Similarly, for Players tobacco ^{210}Pb contents were 0.48 pCi per g dry tobacco, 1.46 pCi per g dry whole smoke condensate, and 52 pCi per g of non-volatile residue after distillation of condensate up to 600° C. The condensate residue was largely water soluble, and most of the ^{210}Pb was associated with the insoluble fraction, at a concentration of $\sim 1 \times 10^4$ pCi per g of residue. Preliminary microscopic examination of the non-volatile, water-insoluble residue of the condensate revealed small irregular particles resembling combustion products, with a maximum diameter of ~ 4 μm. Successive extractions of the residue with dilute and concentrated HCl and HNO_3 resulted in the incomplete solution of the particles and their ^{210}Pb content. After acid extraction, translucent orange particles with the appearance of cured trichome heads were prominent in the residue.

Thus ^{210}Pb is highly enriched in the insoluble particulate fraction of inhaled mainstream smoke. Presumably the volatile smoke constituents are dispersed widely and removed rapidly from lung surfaces. Water-soluble constituents also will be quickly removed from their sites of deposition. The insoluble particles will be further fractionated during deposition and clearance, depending on their physical properties and solubility in lung fluid. The preliminary results indicate that the type of insoluble smoke particles that will persist and accumulate in the bronchi of smokers is between $\sim 10^4$ pCi per g, the activity of water-insoluble smoke particles, and $\sim 10^5$ pCi per g, the estimated activity of pyrolysed trichome heads.

Bronchial epithelium dose estimates

Based on the measured concentrations of ^{210}Po in epithelial samples, Little and Radford estimated a maximum dose of $\sim$200 rem per 25 yr to lower-lobe bifurcations[3]. Holtzman's[8] questions regarding this estimate are answered by the presence of ^{210}Pb in insoluble particles of high specific activity. The insoluble particles should, at least in part, persist sufficiently long to allow ingrowth of the ^{210}Po daughter activity. This possibility can be assessed by analysis of ^{210}Pb and ^{210}Po in small bronchial bifurcation specimens from deceased cigarette smokers.

For a single insoluble particle with 3×10^{-6} pCi ^{210}Pb (the average for North Carolina flue-cured tobacco trichomes) and a ^{210}Po:^{210}Pb ratio of 0.8 (corresponding to particle residence time of 10^3 d in the bronchi) the α radiation dose to cells within the α range ($\sim$6 cell diameters) would be about 0.5 rad or 5 rem per year. However, it has been reported[20] that the pulmonary accumulation of insoluble dust particles involves a sequestering tissue reaction which results in high local dust concentrations in plaques or nodules. The cumulative α radiation dose to lung cells exposed continuously to high concentrations or clusters of insoluble smoke particles will substantially exceed the estimated maximum of 200 rem per 25 yr based on ^{210}Po tissue measurements[3]. ^{210}Po and ^{210}Pb measurements of small bronchial epithelium tissue specimens from deceased smokers, as well as α autoradiography of thin tissue sections, will be needed to assess the actual α dose distribution.

The presence of insoluble particles of high specific ^{210}Pb activity in mainstream cigarette smoke should lead to their accumulation in the bronchi of smokers with residence times sufficient to allow ingrowth of the ^{210}Po daughter radioactivity. This sequence of events must explain the high local concentrations of ^{210}Po observed[2] in the bronchial epithelium bifurcations of smokers which indicate a maximum α dose of some 200 rem per 25 yr[3]. High concentrations or clusters of these insoluble smoke particles may give rise to a much higher dose in small volumes of tissue.

A significant excess incidence of lung cancer has been observed in all groups of uranium miners exposed to more than 120 working level months (WLM) of radon daughter exposure[20]. The corresponding α radiation dose, about 0.5 to 1.0 rad per WLM[21], is 60 to 120 rad, or 600 to 1,200 rem. Correspondingly high α radiation doses in smokers seem to be restricted to relatively small volumes of tissue, thereby suggesting a reduced risk of carcinogenesis. The results for internal emitters reported by Cember[22], however, indicate that the risk for a given cumulative radiation dose may increase significantly at lower dose rates and longer periods of exposure, suggesting a higher risk for smokers.

Asbestos workers who smoke cigarettes have a very much

higher incidence of bronchial cancers than cigarette smokers[23], whereas no excess incidence of bronchial cancers was observed for asbestos workers who do not smoke. It was also reported[24] that insoluble dust accumulations in the bronchi contribute to lymphatic stagnation and thus to a larger accumulation of metabolic products. On this basis it is possible that the higher bronchial cancer risk among asbestos workers who are smokers may be due to the accumulation of a larger burden of insoluble ^{210}Pb smoke particles.

The case for insoluble α emitting particles as the primary agent of bronchial cancer among smokers is reinforced by other lines of evidence. The carcinogenicity of the chemical carcinogens in cigarette smoke has not been demonstrated for the low concentrations which occur in smoke. Insoluble radioactive particles rather than volatile constituents of smoke would seem to be the more logical agent for excess cancers in smokers on the basis of the enhanced cancer risk among smokers who inhale deeply and smoke unfiltered cigarettes, the slow decrease in the residual risk with time following cessation of cigarette smoking, and the occurrence of excess cancers in other organs of the respiratory and gastrointestinal tracts of smokers[25]. Additionally the specific α radioactivity of insoluble smoke particles approaches that of ThO_2 which was widely used as a contrast medium in human radiography and gave rise to carcinomas of the liver and other soft tissues without involvement of chemical carcinogens[26].

Thus, it seems that α radiation from ^{210}Po in insoluble smoke particles may be the primary agent of bronchial cancer in smokers. If so, a significant risk of cancer can be attributed to chronic exposure to low levels of insoluble α emitting particles which give rise to whole organ burdens of only a few pCi of α activity, but involve very high concentrations locally in small volumes of tissue.

I thank S. E. Poet for measurements of ^{210}Pb and ^{210}Po and Art Fong and John Gardner for collecting tobacco trichomes. I also thank Ashok Taori who directed my attention to the nature and distribution of tobacco trichomes. Tobacco and condensed smoke samples were supplied by John Benner and J. H. Smiley of the University of Kentucky and J. A. Weybrew of the University of North Carolina.

Class of promoter sites for *Escherichia coli* DNA-dependent RNA polymerase

Bernard Allet, Richard J. Roberts, Raymond F. Gesteland & Ruth Solem

Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724

Some promoters for E. coli *RNA polymerase contain either of two nucleotide sequences recognised by Hind endonucleases, GTCGAC or GTTAAC. Such promoters are found not only in the DNA of bacteriophages (λ and T7) but also in that of mammalian viruses, including the simian virus 40 and the human adenovirus 2.*

PROMOTER sites for *Escherichia coli* DNA-dependent RNA polymerase have been defined genetically by mutations that abolish the initiation of transcription. Attempts to define these sites biochemically have shown that, *in vitro*, strong complexes form between *E. coli* RNA polymerase and specific sites on Lac[1], T7[2,3], λ[4] and fd[5,6] DNA. It seemed likely that these strong binding sites for RNA polymerase were the genetically defined promoter sites, although there was no direct evidence. The first such evidence came from the observation by Maniatis *et al.*[7] that polymerase binding protects the early leftward promoter (p_L) in λ DNA from cleavage by the endonucleases prepared from *Hemophilus influenzae*. We report here results that confirm and extend these data.

The *E. coli* RNA polymerase recognises many promoters

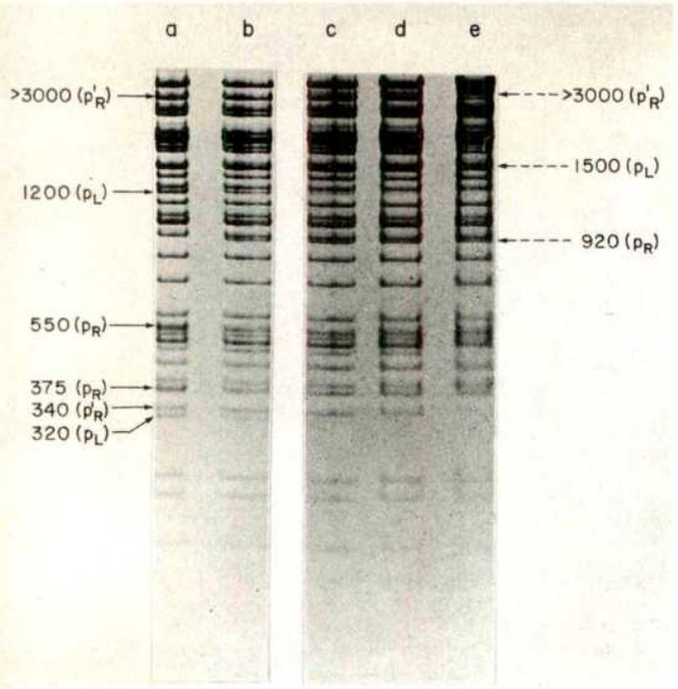

FIG. 1 Polymerase protection of Hind cleavage sites in λ DNA. RNA polymerase and λcI857S7 DNA were prepared as described previously[14]. λcI857S7 DNA (10 μg) in 250 μl (final volume) of 6.6 mM Tris-Hcl, *p*H 7.5, 6.6 mM $Mg(CH_3COO)_2$, 6.6 mM β-mercaptoethanol was incubated at 37° C for 40 min with various amounts of polymerase: (a) no addition; (b) 5 μg (molar ratio of enzyme to DNA, 30:1); (c) 10μg; (d) 12.5 μg; and (e) 50 μg. A 5 μl sample of the Hind endonucleases[12] was added to each sample, and incubation was continued at 37° C for 12 h. The reaction mixture was chilled to 4° C and extracted with phenol, previously saturated with 10 mM Tris-HCl, *p*H 8.0, 1 mM EDTA, and the aqueous phase was precipitated with two volumes of ethanol at −20° C. The samples were submitted to polyacrylamide gel electrophoresis, and the bands were stained with methylene blue as described previously[12]. Fragments containing DNA sequences from the promoter sites p_L, p_R, and p_R' are shown by the solid arrows. The dashed arrows point to fused fragments, which arise as a consequence of the protection of Hind cleavage sites by RNA polymerase. The fused fragments include the indicated promoter sites, and their sizes are expressed in base pairs, as described previously[12].

in bacterial and phage DNAs, and there is evidence that it also transcribes *in vitro* the DNA from mammalian viruses such as SV40[8] and adenovirus-2[9]. *A priori*, these facts suggest that either (1) the various promoters share a nucleotide sequence specifically recognised by the *E. coli* RNA polymerase or (2) the promoters vary in primary structure but display, in their secondary or tertiary structures, similarities which give them a specific affinity for the polymerase.

Our results suggest that several promoters, recognised by the *E. coli* RNA polymerase, are identical in at least part of their nucleotide sequence. Such promoters are found not only in the phage genomes but also in the DNA of two mammalian viruses, SV40 and adenovirus-2. These conclusions are based on the observation that the specific binding of the *E. coli* RNA polymerase protects these promoters from cleavage by an endonuclease prepared from *Haemophilus influenzae*.

The restriction endonuclease of *H. influenzas* Rd contains at least two activities, Hind II and Hind III, separable by phosphocellulose[10] or DEAE chromatography and each recognising two hexanucleotide sequences. It is not known, however, whether Hind II and Hind III each contain but a single enzyme of dual specificity or whether the fractions Hind II and Hind III themselves contain two or more different enzymes. Furthermore, *H. parainfluenzae* contains a restriction endonuclease, Hpa I, believed to recognise one of the two sequences recognised by the enzyme Hind II, as judged by its action on SV40 DNA[10,11]. This assumption is strengthened by our observation that digestion of λ DNA with the combination Hind II/Hind III in the presence or absence of Hpa I leads to an identical pattern of cleavage products[12]. Smith and Wilcox found that the Hind endonucleases recognise two palindromes of six bases on T7 DNA[13]. Because purified Hind III does not cleave T7 DNA (our unpublished result) these palindromes represent the nucleotide sequences recognised by Hind II, which are GTTAAC and GTCGAC, differing only at the two internal bases. It is not known which sequence is recognised by Hpa I.

We showed earlier that in λ DNA the early promoters p_L and p_R and the late promoter p_R' are cleaved by the Hind endonucleases, because the specific binding of *E. coli* RNA polymerase resulted in the fusion of pairs of fragments which flank these sites. In addition, for two mutants with altered p_L, *sex*1 and *sex*3, cleavage of the promoter was abolished even in the absence of polymerase. However, a mutant with a defect in p_R, *x*13, did not abolish the corresponding Hind cleavage site in the absence of polymerase. We therefore concluded that the Hind sextuplet was only part of the nucleotide sequence responsible for polymerase recognition. Finally, it was suggested that p_L, p_R, and p_R' contain one of the two sequences recognised by Hind II, that sequence which is not cleaved by Hpa I.

When increasing amounts of RNA polymerase were added to λ DNA the protection from Hind cleavage proceeded in the order p_R, p_L, p_R' (Fig. 1). Protection by polymerase still occurred in the presence of ATP or the mixture ATP-GTP (Fig. 2), when the enzyme was believed to form an initiation complex at the promoter site. This supports the view that the strong binding sites for polymerase described here coincide with, or at least overlap, the promoter sites. It does not agree with the suggestion[15] that the RNA polymerase binds far from the initiation site of transcription. By contrast, if all four triphosphates were included in the reaction mixture, the protection was abolished, presumably because the polymerase moves away from the promoter site as it transcribes the DNA. The RNA synthesised was heterogeneous in size, and superimposes a diffuse pattern in the lower part of the gel (Fig. 2). In our experiments, the triphosphates were added after the formation of the polymerase–promoter complexes. If rifampicin, an inhibitor of polymerase binding to the first purine nucleoside triphosphate[16], was added together with the triphosphates, the pattern of protection by polymerase was not altered (Fig. 2).

Other promoter sites in λ DNA[14] (for example, in *b*2 and in the *O-P* region, or p_e and p_e' that control transcription of gene *c*I) failed to protect a Hind cleavage site by binding of *E. coli* RNA polymerase. This raises the possibilities that either (1) these promoters bind the polymerase but do not contain the nucleotide sequence recognised by Hind, or (2) these promoters include a Hind II sextuplet but binding of polymerase is not detected in the test situation used. These possibilities have not been investigated.

Promoter sites including a Hind sextuplet were also detected in T7 DNA. Figure 3 shows that when T7 DNA was preincubated with increasing amounts of *E. coli* RNA polymerase (enzyme:DNA molar ratios from 30 to 250), four sites were successively protected from cleavage by the Hind endonucleases. Under the same conditions, but with Hpa I replacing the Hind endonucleases, two sites were protected, but only at the higher polymerase:DNA ratios. The protec-

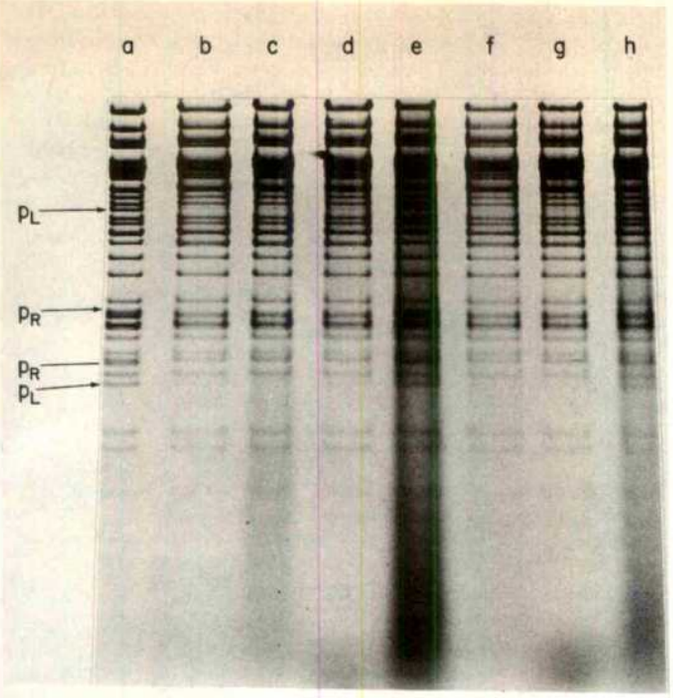

FIG. 2 Effect of ribonucleoside triphosphates on the polymerase protection. λcI857S7 DNA (10 μg) was incubated with RNA polymerase (20 μg) under the conditions shown in the legend to Fig. 1. (Sample (a) is a control without polymerase.) Then various combinations of ribonucleoside triphosphates were added as follows: (a and b) no addition; (c) 60 μg of ATP; (d) 60 μg each of ATP and GTP; (e) 60 μg each of ATP, GTP, CTP, and UTP; (f) 60 μg each of ATP and GTP, and 2 μg of rifampicin; (h) 60 μg each of ATP, GTP, CTP, and UTP, and 2 μg of rifampicin. After incubation at 37° C for 10 min, 5 μl of the Hind endonucleases was added to each sample and incubation was continued at 37° C for 12 h. Extraction with phenol and analysis by polyacrylamide gel electrophoresis were as described in Fig. 1. Fragments containing DNA sequences from the promoter sites p_L, p_R, and p_R' are shown by the solid arrows. The dashed arrows point to fused fragments, which arise as a consequence of the protection of Hind cleavage sites by RNA polymerase.

tion resulted in the appearance of two bands (Fig. 3) missing when preincubation with polymerase was omitted. It seems therefore that in T7 DNA two strong promoters contain the sequence found in p_L, p_R and P_R' in λ DNA, that is, the sequence recognised by Hind II but not by Hpa I. Two weaker promoters were cleaved by Hpa I and differed from the other two. However, because the sextuplets recognised by Hind II differ only by two internal base pairs, as noted above, the promoter sites cleaved by Hind II alone, or cleaved by both Hind II and Hpa I, are closely related in at least part of their nucleotide sequence.

The DNAs from two mammalian viruses, simian virus 40 (SV40) and adenovirus-2 (Ad2) stimulate *in vitro* transcription by the *E. coli* RNA polymerase[8,9]. Interestingly, in each of these viral DNAs, binding of the *E. coli* polymerase prevented cleavage by Hind at one site. In SV40 DNA the Hind cleavage site between fragments B and G (Fig. 5*A*) was protected, at position 18% on the standard map (Fig. 4). In fact, this site was cleaved by Hpa I, and polymerase binding protected one site from cleavage by this endonuclease (Fig. 5*A*). It seems therefore that a promoter for *E. coli* polymerase in SV40 was cleaved by Hpa I, as were two promoters in T7 DNA. Dhar *et al.*[17] have shown that *in vitro* transcription of SV40 DNA is initiated in this region of the SV40 genome and proceeds anticlockwise through the G fragment. Their data show that the G fragment, which is about 350 base pairs long, is cleaved by the restriction endonuclease RII into two fragments. The smaller of these represents approximately one-third of the Hind G fragment, that is, 120 base pairs, and contains the first sequences transcribed. Extensive sequence analysis of this transcript[17] revealed that the recognition site for the RII endonuclease occurs at position 115 from the start of the transcript. This implies that the promoter is extremely close to the Hind recognition site and also close to the start of transcription, in agreement with the results obtained for λ DNA (Fig. 2). Figure 5*B* shows that Ad2 DNA also contains a Hind cleavage site that can be protected by *E. coli* RNA polymerase. The protection was not observed with Hpa I. It is tempting therefore to speculate that this site is a promoter for *E. coli* RNA polymerase *in vitro*, of the same type as the λ and T7 promoters. An estimate of its location in Ad2 DNA can be deduced from the cleavage pattern of the hybrid Ad2-SV40 (Ad2$^+$ ND1) DNA. Ad2$^+$ ND1 derives from Ad2 by two alterations in the viral DNA. (1) A portion of Ad2 DNA has been deleted between the positions 14.0% and 19.4%, measured from one end of the DNA molecule[18]. (2) Instead, a portion of SV40 DNA has been inserted, covering the region between 11% and 28% of the standard SV40 map. Interestingly, Ad2$^+$ ND1 contained the Hpa I cleavage site between SV40 DNA fragments B and G, and Fig. 5*C* shows that two fragments, missing from Ad2 DNA, were fused in the hybrid as a consequence of the polymerase protection. However, the polymerase failed to protect any other Hind cleavage site in the hybrid. Thus it can be deduced that the polymerase binding site that was detected in Ad2 DNA must be in the part of the molecule that is deleted in the hybrid, that is, somewhere between map positions 14.0% and 19.4%.

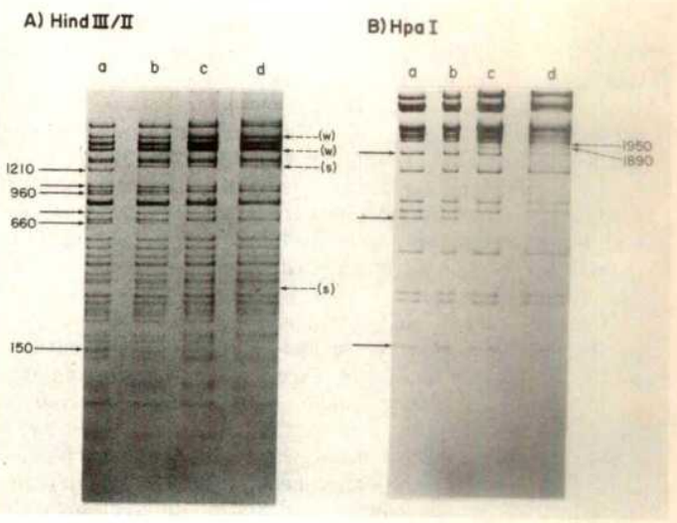

FIG. 3 Polymerase protection of Hind and Hpa I cleavage sites in T7 DNA. T7 DNA (8 μg) was incubated with varying amounts of RNA polymerase as shown in the legend to Fig. 1. (a) no addition; (b) 5 μg; (c) 12.5 μg, and (d) 40 μg. Then 5 μl of the Hind endonucleases (A) or 10 μl of purified Hpa I (gift of J. Sambrook[11]) (B) was added and the incubation was continued at 37° C for 12 h. The samples were prepared and analysed as described in Fig. 1. The dashed arrows point to fused fragments which arise from the protection of cleavage sites. The letters in parentheses indicate whether the fused fragments contain a weak (w) or a strong (s) promoter site, as judged by the amount of polymerase needed to detect their appearance. The solid arrows point to fragments which progressively disappear when increasing amounts of polymerase are tested. The sizes of the fragments are expressed in base pairs (Fig. 1).

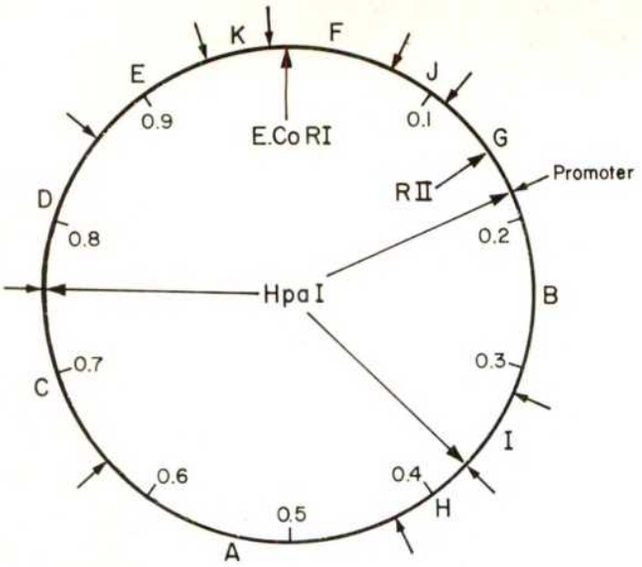

FIG. 4 Physical map of fragments in SV40 DNA. The map was adapted from Danna *et al.*[10] The arrows outside the circle indicate the sites of cleavage by the Hind endonucleases, and the resulting fragments are designated by letters (A to K)[10]. The sites of cleavage by Eco RI, Hpa I, and the site of cleavage by RII within the Hind fragment G are indicated by arrows inside the circle.

Our results support the conclusion that a class of promoters for *E. coli* RNA polymerase shares identical nucleotide sequences, at least those contained in the specific sextuplets recognised by Hind II. The strongest evidence that a part of the Hind sextuplets actually belongs to the promoter sites comes from the fact that two mutations that altered a genetically defined promoter in λ DNA, *sex*1 and *sex*3, also altered the nucleotide sequence recognised by Hind II. Clearly, sequences outside these sextuplets are also involved in specifying promoter sites, because only a small proportion of the Hind II cleavage sites can bind polymerase. The lengths of these additional sequences are unknown, but they presumably could not exceed the 47 to 52 base pairs protected from pancreatic DNase digestion when *E. coli* polymerase binds to promoters[3]. To what extent the promoter sites described here are homogeneous in their DNA sequences outside the Hind II sextuplets has yet to be determined.

It must be noted that, for λ and T7 DNAs at least, the number of RNA polymerase molecules (30–250) needed to protect Hind cleavage sites exceeded by far the number of promoters or strong binding sites (7–10) reported in these DNAs[15,19]. This indicates that either (1) only a fraction of the molecules in the polymerase preparation could bind DNA; or (2) the experiments were performed under conditions of kinetic control and reflect differences in the rate of complex formation; or (3) the experiments were performed under conditions of thermodynamic control, equilibrium was attained, and the differences reflect differential affinities; or (4) several polymerases were bound at single sites. In the latter case, however, the multiple polymerase molecules would probably not have been arrayed linearly, because polymerase binding to promoter sites only protects stretches of 47–52 nucleotide base pairs from digestion by pancreatic DNase[3]. Experiments are in progress to decide among these possibilities.

As we pointed out earlier, several promoter sites are not identified by polymerase protection of a Hind II site. Such promoters may not contain any of the Hind II sextuplets. Alternatively, they may include one of them but not bind the polymerase to a detectable extent under the conditions

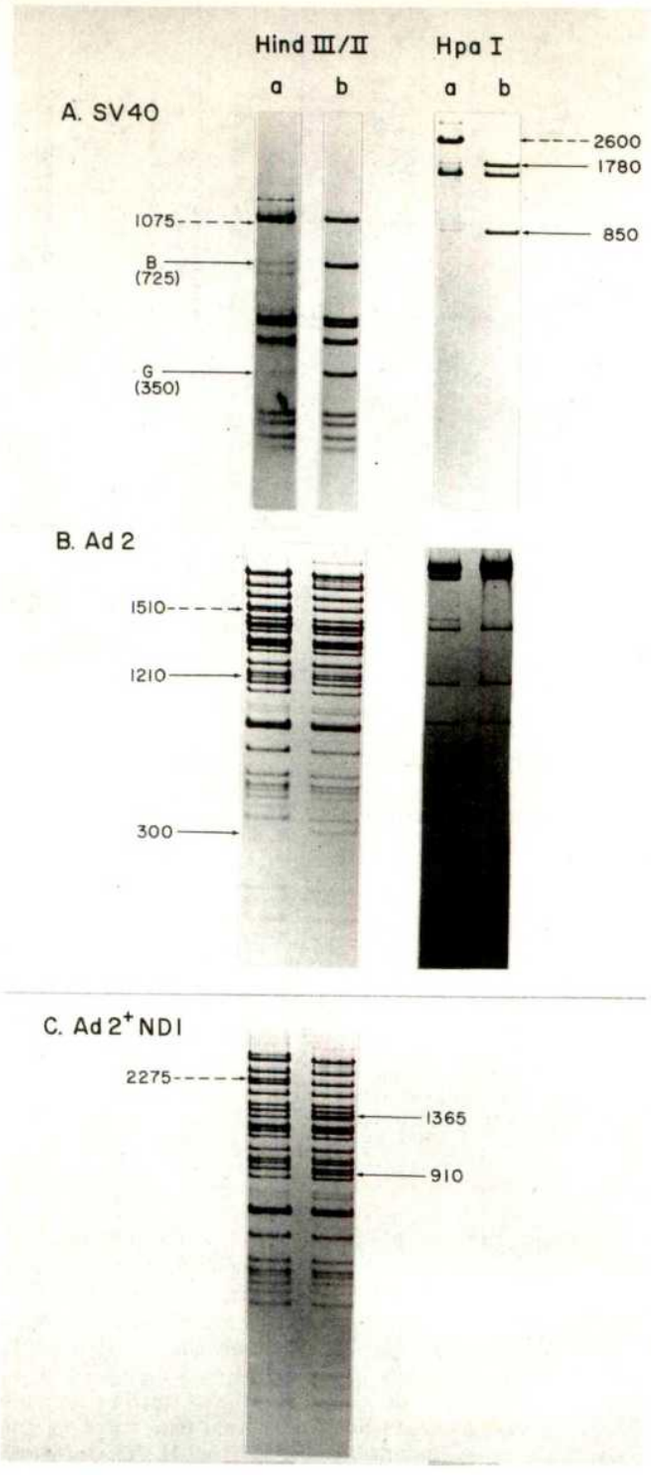

FIG. 5 Polymerase protection of sites cleaved by Hind III/II and Hpa I endonucleases in SV40, Ad2, and Ad2⁺ ND1 DNAs. SV40 (A), Ad2 (B), and Ad2⁺ ND1 (C) DNAs (10 μg) were incubated in the presence (a) or absence (b) of *E. coli* RNA polymerase (20 μg) at 37° C for 40 min as described in the legend to Fig. 1. Then 5 μl of Hind III/II was added and the incubation was continued at 37° C for 12 h. Subsequent extraction and analysis were performed as described in the legend to Fig. 1. In the case of samples subsequently digested with Hpa I (10 μl), 5 μg of each DNA was used with 20 μg of polymerase. The solid arrows indicate fragments that are present when polymerase is omitted from the reaction mixture. The dashed arrows indicate fused fragments arising as a result of polymerase protection. The sizes of the fragments are expressed in base pairs. In the Hind III/II pattern of SV40, the positions of fragments B and G (Fig. 4) are indicated.

used. The first hypothesis was verified in one case at least, that of the wild type promoter for the *lac* operon. This conclusion arose from the mapping data of the Hind II-III fragments generated from *lac* DNA in the well characterised λ*plac*5 DNA[20] (in collaboration with P. Tiollais, unpublished data). The mapping data indicate that there is no Hind cleavage site within the first 500 base pairs in the *lac* DNA, which, in this insertion, extends from the promoter (*p*) through the operator (*o*) to the end of the gene for β-galactosidase (*z*). This is a clear indication that *p* is not cleaved. Thus it seems that the promoter sites analysed in this report represent a subset only of the promoters recognised by *E. coli* RNA polymerase.

The fact that we could identify a strong promoter site for the *E. coli* polymerase in the DNAs from two mammalian viruses, SV40 and Ad2, is intriguing. Clearly, a random base distribution would not be likely to generate a sequence of this presumed complexity in DNA molecules as small as 26 million daltons (Ad2) or 3 million daltons (SV40). Thus it is tempting to believe that these sequences are of biological importance for SV40 and Ad2. In SV40 DNA, the early RNA molecules are synthesised *in vivo* from a promoter located at a site widely distant from the promoter site recognised by the *E. coli* polymerase. It seems therefore that in the early stage of the viral development the mammalian polymerase does not recognise the same promoter site as is recognised by the *E. coli* enzyme. Whether the mammalian enzyme recognises this site at some later stage is unknown. It would be of particular interest to carry out similar experiments with the mammalian polymerase.

Since this report was submitted for publication, Drs S. Weissman and K. Murray, who independently communicated this result to us, have shown that Hpa I recognises the sequence GTTAAC. This means that the sequence GTCGAC is associated with the strong binding sites for *E. coli* RNA polymerase, and the sequence GTTAAC is associated with the weaker binding sites. Furthermore, from the recent sequence analysis communicated by Dr Weissman it is now known that the starting site for transcription in fragment G of SV40 is located 29 base pairs from the Hpa I sextuplets which delimits fragments B and G.

We thank J. Sambrook and P. Sharp for useful discussions and for Hpa I endonuclease and DNA from Ad2+ ND1. This investigation was supported by a US Public Health Service research grant from the National Cancer Institute and a research grant from the US National Science Foundation to R. F. G.

Promoters are in the operators in phage lambda

Russell Maurer, Tom Maniatis & Mark Ptashne

Biological Laboratories, Harvard University, Cambridge, Massachusetts 02138

E. coli *RNA polymerase binds to a specific site within each λ operator. This DNA site is recognised by three proteins: RNA polymerase, the λ phage repressor, and a restriction endonuclease (Hin).*

EACH of the two operators in bacteriophage λ, O_L and O_R, consists of catenated, nonidentical repressor binding sites[1–3] (Fig. 1). At each operator, repressor first binds to a terminal site, and subsequent molecules add in the direction opposite to that of transcription of the adjacent controlled operons. Moreover, although the two operators are not identical, each contains, between the first and second repressor binding sites, the same short sequence that is cut by a restriction endonuclease (Hin) isolated from *Haemophilus influenzae*. We show here that both operators contain a specific binding site for RNA polymerase (promoter). This operator–promoter site includes the restriction endonuclease target, and we conclude that repressor, RNA polymerase, and Hin recognise shared DNA sequences. A preliminary account of related experiments was presented elsewhere[3]. Experiments similar to some of those recorded here and in ref. 3 are also reported in the accompanying article by Allet *et al.*[4]

Promoter mutations in the operators

A mutation has been described, called *sex*1[5] that decreases transcription *in vivo* and *in vitro* of the operon controlled by

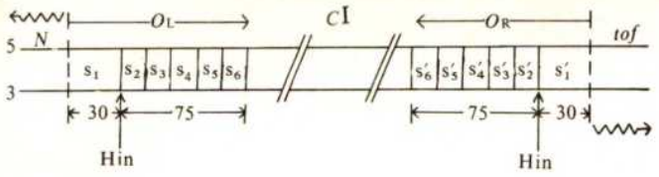

FIG. 1 Schematic representation of the λ operators and adjacent genes. The wavy arrows show the direction of transcription of the repressor-controlled genes *N* and *tof*. Two arrows indicate the order of repressor binding from the first sites (S_1 and S_1') in O_L and O_R. The Hin cutting sites in O_L and O_R are indicated along with the number of base pairs within the operators on either side of each Hin cut. The repressor gene is *cI*.

O_L[6,7]. We have shown[3] by RNA polymerase-DNA binding experiments that *sex*1 decreases the affinity of a DNA fragment bearing the leftward promoter, P_L, for RNA polymerase, and we concluded therefore that the mutation is in that promoter. We now wish to ask, where is *sex*1, and hence the promoter, located in relation to O_L?

The experiment of Fig. 2 shows that *sex*1 is located within O_L, in the sequence recognised by Hin. We compared a Hin digest of whole λ wild-type DNA with that of λ*sex*1 DNA (*a* and *b*). The figure shows that the fragments designated Hin 320 and Hin 1125, generated from λ wild-type DNA, are replaced by a larger fragment about 1,450 base pairs long in the digest of λ*sex*1 DNA. This is the only difference in the two gel patterns. To show that this difference is attributable to the *sex*1 mutation itself, and not to some irrelevant difference between λ wild-type and λ*sex*1 DNA, we isolated revertants with wild-type plaque morphology from λ*sex*1, as described in the legend to Fig. 2. The figure (*c* and *d*) shows Hin digests of examples of the two classes of revertants recovered. In one (*d*) the original Hin cutting site is restored, and in the other this site remains defective. (Three out of five revertants tested, not necessarily representing independent back mutations, lack the original Hin site.) We have shown previously[2,3] that the junction between Hin 320 and Hin 1125 is the Hin cutting site in O_L. We conclude, therefore, that the *sex*1 mutation alters the sequence of the O_L Hin site. Allet and Solem[8] have reported, and we have confirmed (unpublished), that *sex*3, an independently derived leftward promoter mutation (personal communication from M. Gottesman), also alters the O_L Hin site.

We have also found that DNA bearing a rightward promoter mutation, *x*3[9], lacks the O_R Hin site (not shown), in formal analogy to the alteration of the O_L Hin site by *sex*1. Although we have not studied x^+ revertants, this finding is consistent with other evidence, presented below, that the rightward promoter includes the O_R Hin site. (It should be noted that not all so-called x mutations alter the O_R Hin site; *x*13, for example, located to the right of *x*3[9], does not affect this site[8]. As suggested by Ordal and Kaiser[9], who presented evidence for interpenetration of operator and promoter at O_R, the mutation *x*13 may block rightward transcription by action distal to the promoter.)

Binding of RNA polymerase to Hin sites

The experiment of Fig. 3 shows that RNA polymerase binds with special avidity to the two Hin sites located in O_L and O_R. To perform this experiment we digested whole ^{32}P-labelled λ DNA with Hin in the presence of varying amounts of RNA polymerase. Most of the Hin cutting sites were unaffected by the presence of polymerase, but at the lowest ratios of polymerase to DNA used two sites were specifically protected. These two sites are those previously mapped in O_L

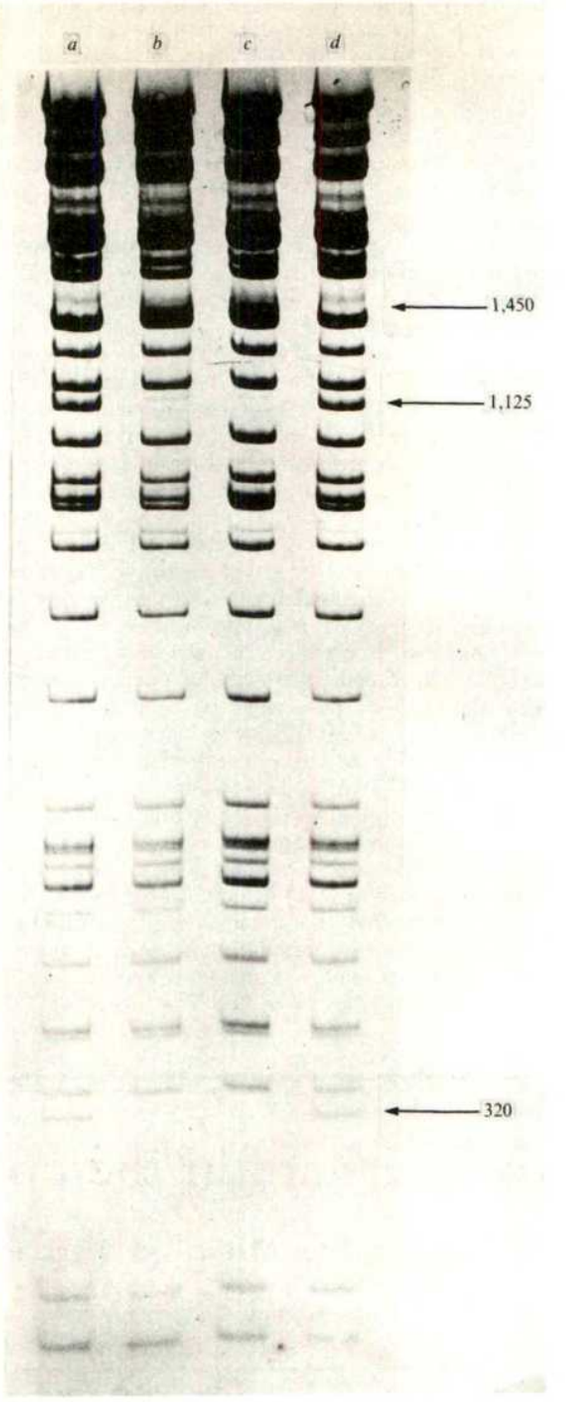

FIG. 2 Hin digestion patterns of DNA from λ, λ*sex*1 and two λ*sex*$^+$ revertants of λ*sex*1. DNA isolated from each phage (100 μg) was digested with Hin as described in ref. 3 except that no additional carrier DNA was added. Hin was isolated from the exonuclease-free strain Rd com^{-10} (ref. 13) as described in ref. 3. The digested DNA was fractionated by electrophoresis in a 3.5% TBE gel[1], and visualised by staining with 0.05% methylene blue. Sex$^+$ revertants of λ*cI*857*sex*1*S*7 were isolated by picking large plaques on an *su*III$^+$ strain, which is permissive for the growth of *S*7 phages. An *su*$^-$ strain was then lysogenised separately with these revertants, and high titre stocks were prepared by thermal induction. *a*, λ Wild type; *b*, λ*sex*1; *c*, λ*sex*$^+$ revertant lacking the O_L Hin site; *d*, λ*sex*$^+$ revertant bearing a restored O_L Hin site. The labels in the figure give the number of base pairs in the indicated fragments, as determined in ref. 3.

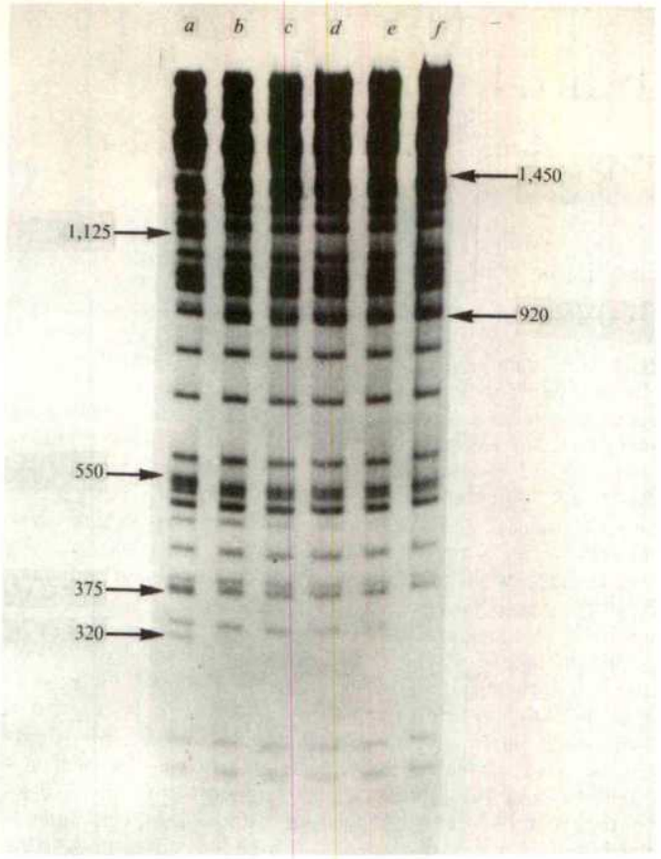

FIG. 3 Autoradiogram of λ DNA digested with Hin in the presence of various amounts of RNA polymerase. 3 μg of ^{32}P-labelled λ DNA (about 10^5 c.p.m. μg^{-1}) was incubated with RNA polymerase for 5 min at 37°C in a solution containing 50 mM KCl, 8 mM $MgCl_2$, 20 mM Tris, *p*H 8.0, 0.1 mM DTT, 5% DMSO and 0.1 mM each rATP and rGTP. Then 50 μl of Hin buffer[2] was added with Hin, and the mixture was incubated for another 60 min at 37°C. After phenol extraction the products were examined as in Fig. 2. *a*, No RNA polymerase (RNP); *b*, 1.5 μg RNP; *c*, 3 μg RNP; *d*, 4.5 μg RNP; *e*, 6 μg RNP; *f*, 7.5 μg RNP.

and O_R. Thus Hin 320 and Hin 1125, the junction of which is in O_L, were replaced by a larger fragment, and, similarly, Hin 375 and Hin 550, the junction of which is in O_R[2], were replaced by a larger fragment. Figure 3 also shows that at ratios of RNA polymerase to DNA higher than that required to protect the Hin sites in O_L and O_R, two additional sites were protected. Allet and Solem[8] suggest a location for one of these additional sites, but the location of the fourth site is as yet unknown.

The RNA polymerase protection of the O_L Hin site in whole λ DNA is consistent with data presented elsewhere showing a similar effect of polymerase on Hin digestion of a DNA fragment bearing an intact O_L[3]. However, the protection of the O_R Hin site, also observed in the experiment of Fig. 3, contradicts our earlier unexplained failure to observe protection of that site when the experiment was performed with a specific fragment bearing an intact O_R. In recent experiments with this fragment we have observed protection of the Hin site in O_R at ratios of polymerase to DNA comparable with those used in the experiments of Fig. 3 (unpublished).

Relationship of promoter to operator

The results of our experiments show that at both O_L and O_R, repressor and RNA polymerase recognise in common a specific DNA base sequence which includes a Hin restriction endonuclease cutting site. Since the Hin site occupies a corresponding position in each operator, the relationship of promoter to operator is apparently the same at O_L and O_R. These findings confirm a specific mechanism of repression at the λ operators: repressor bound to the operator prevents binding of RNA polymerase to the promoter. It is a remarkable fact that mutations in the operators can affect RNA polymerase binding without, apparently[10], affecting repressor binding.

Our results also require a reconsideration of the hypothesis of RNA polymerase 'drift'[11] between promoter and transcription start point. From the following facts we deduce that the O_L Hin site (and hence the RNA polymerase binding site) is within 30–50 base pairs of the start point of transcription of gene *N*. First, there are 30 base pairs between the O_L Hin site and the left terminus of O_L[2], and second, the left terminus of O_L is within 20 base pairs of the start point of transcription[3]. Our deduction is proved directly by DNA sequence analysis which reveals that 33 base pairs separate the O_L Hin site from the start point of transcription (Maniatis *et al.*, in preparation). We do not yet know precisely how many bases on each side of the Hin cutting site are covered by bound RNA polymerase, but since DNA-bound RNA polymerase covers about 40 base pairs[12], it is possible that polymerase bound at the O_L Hin site extends to the transcription start point. In any case it is clear that RNA polymerase 'drift', if it occurs at all, is certainly over a much shorter distance than the 100–300 base pairs previously estimated[11].

We thank Allan Maxam for RNA polymerase, David Friedman and Louis Reichardt for phage strains and Debbie Gernes and Andrea Jeffrey for technical assistance. This work was supported by a grant from the US National Science Foundation.

Note added in proof: A slightly modified interpretation of our findings, which we cannot yet exclude, is that RNA polymerase binds adjacent to (that is within a few bases of) the Hin site rather than directly over it. This scenario would require a more complicated explanation of the effects of the *sex* mutation than the one we have suggested.

Clonal cell lines from the rat central nervous system

D. Schubert, S. Heinemann, W. Carlisle, H. Tarikas, B. Kimes, J. Patrick, J. H. Steinbach, W. Culp & B. L. Brandt

Department of Neurobiology, The Salk Institute, PO Box 1809, San Diego, California 92112

Five neuronal and a large collection of putative glial cell lines from the rat central nervous system have been established in clonal cell culture and partially characterised. These cells shed new light on the distribution of neurotransmitter synthesis and brain-specific antigens among nerve and glia.

ALTHOUGH the C1300 mouse neuroblastoma[1,2] has been useful for studies of the differentiation and trophic interactions of nerve cells, many more neuronal cell lines will be required before generalisations can be made about the behaviour of these cells in culture and maximum use made of the clonal culture system. This also applies to the glia and other satellite cells, whose role in the metabolism and physiology of nervous tissue is poorly understood; only a few clonal cell lines of glial origin have been described[3–5].

To establish defined cell lines from the central nervous system (CNS), cells must first be adapted to permanent culture and cloned; at present neoplasms are the only efficient source of dividing cells for this purpose. The established clones must then be sorted into cell types, for example, neurones must be distinguished from glia, and, among the glial cells, astrocytes from oligodendrocytes. We describe here an attempt to establish and characterise several clonal cell lines from the rat CNS. Of approximately 120 cell lines isolated from independently arising tumours so far, some properties of 22 clones from independently arising tumours are described.

Establishment of cell lines

Neoplasms were induced transplacentally with nitrosoethylurea (NEU)[6]. BDIX rats were injected 15 d after conception with 4.0 mg of NEU per 100 g body weight, which reduced the litter size by 50%. Between 4 and 10 months after birth, approximately half the offspring had symptoms of extreme nervous system disorders and were examined for tumours. In 93% of the animals, tumours were found in the CNS; the others had tumours in other areas. Excised tumours were minced finely in modified Eagle's medium containing 20% foetal calf serum[7], cells (including pieces of tissue) were diluted and 1×10^4–1×10^6 cells were plated on Falcon 60 mm tissue culture dishes. Each dish was examined periodically for cell proliferation, and as areas of extensive growth were found, cells were isolated by cloning rings and transferred to another dish. Since the initial explants contained cells of widely different morphologies, the most complex cell types were selected. When these cells reached confluency, they were either cloned or passaged for further study. Only one clonal cell line was initially obtained from each tumour. Of the fourteen cell lines examined, all were near diploid.

Excitability and morphology

Mammalian nerve or muscle can be distinguished from glia and most other cells, as the former have electrically excitable membranes[8]. To assay for membrane excitability, cells were impaled with a microelectrode as described elsewhere[9]. When penetration was achieved, defined as a stable resting potential greater than −30mV, the cells were monitored for electrical excitability by anode-break stimulation. Table 1 shows that at least five of the cell lines (B35, B50, B65, B103 and B104) could produce a regenerative action potential. Cells were scored as negative if there was no evidence of a regenerative response after at least twenty penetrations with resting potentials greater than −30mV. Negative data, however, can be false due to technical difficulties[10]. Although electrical excitability indicates that a minimum of five of the cell lines are of neuronal or muscle origin, on the basis of other evidence discussed later, it is unlikely that any are of muscle origin.

In some nerve and muscle cells the presence of acetylcholine (ACh) receptors is correlated with electrical excitability, and the binding of ^{125}I-α-neurotoxin can be used to detect these receptors. Using established techniques[11], the number of curare-protectable α-neurotoxin-binding sites was determined in several cell lines (Table 1). Of the twelve new lines examined, three cell lines with excitable membranes have detectable ACh receptors. Clones of the C1300 neuroblastoma and the L6 myoblast line also bind toxin, while 3T3 fibroblasts do not.

After cloning, the cells could be classified into six morphological groups (Table 1 and Fig. 1). Four of the five neuronal lines—B35, B50, B65 and B103—fall into a class with clones of C1300 neuroblastoma (group 2); they all

With noted exceptions, stationary phase cells from passages 5 to 10 after cloning were assayed for enzyme activities, proteins and morphologies as described in the text. The amount of S100 and 14-3-2 is expressed as ng specific protein per 100 ng of total soluble protein. Bovine antigens were used in both cases; these cross react extensively with the respective rat proteins (H. Herschman, personal communication). The enzyme-specific activities are expressed as follows: esterase, using either acetylthiocholine or butyrylthiocholine as substrates, ΔA_{412} per min per mg protein; choline acetyltransferase, pmol ACh formed per min per mg protein; tyrosine hydroxylase, pmol $^{14}CO_2$ released per 20 min per mg protein; glutamic acid decarboxylase, pmol $^{14}CO_2$ released per 20 min per mg protein inhibitable by 1 mM aminooxyacetic acid. The neurotransmitter products were identified chromatographically. GABA assays were done on tricholoroacetic acid soluble cell supernatants using an amino acid analyser with expanded resolution (D.S. and W.C., in preparation). The results are expressed as residues of GABA per 1,000 residues of free amino acids. The effects of serum-free medium and 1 mM dibutyryl cyclic AMP on cell morphology were assayed on exponentially dividing cells and range from no change (−) to the greatest change (+++); an effect greater than (+) is considerable. The percentage hydroxyproline is expressed as the percentage of proline found in secreted protein which is hydroxylated (see ref. 33 for discussion and assay procedures). The binding of ^{125}I-α-neutrotoxin is expressed in 10^{-15} mol toxin bound per mg protein. The morphological groups indicate the general morphologies of the cells (see Fig. 1 and text). Electric excitability is scored as positive if regenerative action potentials are observed, and negative if there was no evidence for this event in at least 20 cells examined with resting potentials more negative than −30mV. C1A and S20 were clones of the C1300 mouse neuroblastoma[12,34], L6 was a clonal rat myoblast line[33], 3T3 was a fibroblast cell line, and P3 an immunoglobulin-secreting plasmacytoma. O-serum, the effect of serum-free medium on cell morphology; DBcAMP, the effect of dibutyryl cyclic AMP on cell morphology; ChA, choline acetyltransferase activity; TH, tyrosine hydroxylase activity; GAD, glutamic acid decarboxylase activity; GABA, residues of GABA per 1000 residues of free intracellular amino acids; AChE, esterase activity using acetylthiocholine as substrate; BChE, esterase activity using butyrylthiocholine as substrate; AChE/BChE, the numerical ratio of the two esterase activities; % HP, percentage of the total secreted proline found as 4-hydroxyproline; S100 and 14-3-2, concentrations of these proteins in cell lysates.

* Exponentially growing cells.

† All assays were done in fused, multinucleate myotubes, except for the effects of dibutyryl cyclic AMP and O-serum medium on cell morphology. Myoblasts are of group 4 morphology.

grow loosely associated with the surface of the culture dish and have relatively spherical, phase-bright cell bodies. A fifth neuronal cell line, B104, has a group 1 morphology, with very long, thin and usually bipolar cells. The other groups consist of cells with short, highly branched processes (group 6), extremely large flat cells (group 5), cells which are large and flat during the exponential phase of growth, but which branch profusely in the stationary phase (group 3), and the fibroblast-like cell (group 4). Whenever more than one cellular morphology was observed during the growth cycle, stationary phase cells were the most complex. This resembles the situation with C1300 neuroblastoma, where under normal conditions cells with long neurites are rare except in stationary phase cultures[2,10].

The C1300 neuroblastoma characteristically responds to the removal of serum and the presence of dibutyryl adenosine 3′,5′-monophosphate (dibutyryl cyclic AMP) by rapidly extending neurites[12–14]. Although dibutyryl cyclic AMP induces morphological transformations in most cells, the effect of serum-free medium on the mouse neuroblastoma seems to be specific. If this response is restricted to cultured nerve cells, only nerve lines should respond to the removal of serum with similar morphological transformations. Table 1 shows that this was the case. Thus the morphological response to low serum concentrations seems to distinguish neuronal from non-neuronal cells in this system. As expected from work on the mouse neuroblastoma and primary cultures of nervous tissue[15], all the neuronal and most of the other cell lines were transformed morphologically in the presence of dibutyryl cyclic AMP (Table 1). A more detailed account of these changes will be presented elsewhere.

Neurotransmitter synthesis

Another distinction between the classes of cells in the nervous system is provided by the enzymes involved in neurotransmitter metabolism. The activities of choline acetyltransferase, tyrosine hydroxylase, glutamic acid decarboxylase, and both acetyl and butyrylcholine esterase were measured in stationary phase cultures as detailed elsewhere[16–19]. Table 1 shows that esterase activity was widely distributed among the cell lines, varying greatly with respect to both absolute amount and the ratio of activities on acetylthiocholine and butyrylthiocholine substrates. Al-

though B6, B19 and B104 have relatively high ratios, demonstrating true acetylcholine esterase, no cell lines approached the activities of C1300 neuroblastoma clones. Choline acetyltransferase is also widely distributed among the cell lines. It has been suggested, on the basis of indirect evidence, that glia synthesise acetylcholine[20]; the data in Table 1 indicate that some of the non-neuronal cell lines in our collection have the requisite enzyme. Amino-oxyacetic-acid-inhibitable glutamic acid decarboxylase activity was restricted to the neuronal cell lines, while γ-aminobutyric acid (GABA) was found in all of the putative nerve and glial lines. Although there was no strong correlation between glutamic acid decarboxylase activity and the ability of the cells to retain GABA, these data again suggest that glial cells can synthesise neurotransmitters. Tyrosine hydroxylase was found in B65 and at least two of the non-neuronal cell lines. With the exception of choline acetyltransferase activity in B65, the data indicate the enzyme specific activities for stationary phase cells only. These activities and the concentrations of the putative neurotransmitters vary as a function of the growth cycle (B. K., H. T., D. S., manuscript in preparation).

As Table 1 shows, several neuronal cell lines contain more than one neurotransmitter synthetic enzyme. For example, B65 contains choline acetyltransferase, tyrosine hydroxylase and glutamic acid decarboxylase activities; B35 and B103 both contain choline acetyltransferase and glutamic acid decarboxylase activities. Although it is generally assumed that an individual nerve cell makes but one transmitter, the evidence for this is not complete. In particular, it is not known if the newly formed nerve cell can synthesise a spectrum of neurotransmitters before it becomes functionally coupled with another cell. Possibly the shift toward predominantly one transmitter is a result of this type of cell-cell interaction, an event not documented in these clonal cultures. Finally, it should be pointed out that the specific activities of the enzymes involved in neurotransmitter metabolism in the cell lines are lower than those observed *in vivo* (Table 1). Since transmitter enzymes may be concentrated at functional nerve endings, and their levels regulated by trophic interactions between cells, the relatively low activities presented here may again reflect a lack of such interactions in these cultures.

Proteins unique to the nervous system

Of several proteins which seem to be localised in the nervous system, S100 and 14-3-2 are thought to be associated with glia and nerve, respectively[21,22], in spite of exceptions[23–26]. Since stationary phase cells exhibited the greatest morphological complexity seen during the growth cycle, they were used for the quantitation of these proteins. (It should be pointed out, however, that the intracellular concentrations of some enzymes and other proteins depend on the stage of the growth cycle both in these and in other cell lines[27,28].) To assay for S100 and 14-3-2, cells were homogenised and the soluble cell fraction was assayed by an indirect radioimmune procedure using iodinated antigen and antisera prepared against the pure antigen[29]. Assays were routinely linearly sensitive between 1 ng and 100 ng for S100 and between 10 ng and 1000 ng for 14-3-2. (Concentrations of 14-3-2 and S100 in whole brain determined by this procedure were similar to those reported using other procedures[30,31].) Table 1 indicates that these proteins are not uniquely associated with either neuronal or non-neuronal cells. Although all the neuronal lines contain detectable 14-3-2, both proteins seem to be distributed independently among the remaining lines. Cells with undetectable levels of both proteins may not be of nerve or glial origin, an observation compatible with the fibroblast-like morphology of most cell lines in this group. These cells, which represent approximately 25% of the induced tumours, have not (with the exceptions of B1 and B56) been included in Table 1. However, cells which contain S100 or 14-3-2 and are not electrically excitable are of probable glial origin[21–26], and the presence of either protein cannot distinguish nerve from glia. Finally, all the cell lines of Table 1 were screened for neurophysin by the methods described for S100 and 14-3-2; none was found.

Some of the cell lines were also screened for secreted hydroxyproline, a marker for collagen[32]. Cells were labelled with ^{14}C-proline and the secreted protein assayed for 4-hydroxyproline[33]. Table 1 shows that all the cell lines examined secreted hydroxyproline. Although there was no absolute correlation with cell groups, these data suggest that more nerve-like group 2 cell lines secrete relatively less hydroxyproline-containing protein than the other morphological groups. This may explain the characteristic loose adhesion of the group 2 cells to the culture dish.

Conclusions from these data

We have drawn the following conclusions from our data. (1) Neoplasms of both neuronal and glial origin can be induced by established procedures in BDIX rats, and the resultant cells can be adapted to clonal cell culture. (2) At least 4% of our neoplasms yielded permanent nerve cell lines. (3) Nerve and glial cells can apparently be distinguished in cell culture on the basis of the effect of serum-free medium on cell morphology. All nerve and most glial cells undergo morphological changes in the presence of dibutyryl cyclic AMP, but only the nerve cells extend processes in the absence of serum. (4) Detectable glutamic acid decarboxylase activity is restricted to nerve lines, while low levels of GABA are also found in glial lines. Choline acetyltransferase and tyrosine hydroxylase activities are found in both nerve and glial cells. These results suggest that glia can synthesise neurotransmitters. (5) Some clonal nerve cell lines contain the enzymatic activities required to synthesise more than one neurotransmitter. (6) The nervous system proteins S100 and 14-3-2 are found in various combinations in both nerve and glial cell lines. All nerve cells contain detectable 14-3-2 while not all putative glial cells contain detectable S100.

Neuronal and non-neuronal lines can be distinguished on the basis of membrane excitability and neurotransmitter synthesis, but the sorting of non-neuronal lines has been difficult. On the basis of S100 and 14-3-2 protein synthesis, it can be argued that most of the cell lines presented in Table 1 are of either nerve or glial origin. It has been impossible, however, to group the putative glial cells on any basis except morphology. More specific criteria are needed.

Because all the cell lines in Table 1 derive from independently arising CNS tumours, they have greater functional diversity than is possible using one neoplasm. For example, clones of C1300 neuroblastoma have many different properties[34] but probably the original tumour was derived from a single cell, and the various stem cells resulted from later mutation and chromosome rearrangement[10]. In contrast, the rat nerve cell lines are not far removed from the original neoplastic cell, their karyotype approaches normal, and the clonal lines seem stable. Functional diversity and genetic stability are required if clonal lines are to be used with maximum effectiveness in the study of the mechanisms underlying the function of the mammalian nervous system.

We thank Dr M. Cohn for support and Dr A. J. Harris for his contributions. We also thank Dr Harvey Herschman for the 14-3-2 and S100 proteins and their respective antisera, and Dr R. McCaman for help with enzyme assays. This work was supported by grants from the Ford, Rockefeller and Sloan Foundations and the Muscular Dystrophy Associations of America to the Salk Institute neurobiology group.

Lunar magnetism and an early cold Moon

D. W. Strangway

Models of lunar magnetism have involved dynamo action in a fluid core in an early hot Moon; an early cold Moon magnetised some time before 4.0×10^9 *yr ago, which has subsequently heated up; and local field sources which, in some models, are related to impact. Here we examine the second possibility and show that provided the Moon contained a few percent of metallic iron and was exposed to an extra-Lunar field of about* 10 *or* 20 *oersted while much of it was still below the Curie point of iron, a restricted class of thermal evolution models, which satisfy the known constraints, can be derived.*

One model of the thermal history of the Moon (see ref. 1–6) which has gained wide acceptance, involves a Moon which accreted cold but which was heated from the outside during the final stages of accretion. This would have given rise to a molten shell very early on in lunar history, and formed the crust which is indicated by seismic studies[7–9]. The interior of the Moon, however, would have been cool during its early history and would have warmed up because of radioactive heating only relatively recently, thus forming the molten or partially molten core which is indicated seismically [7–9]. Early papers accounting for the magnetic field of the Moon suggested an initially hot Moon in which an iron core formed. Although moment of inertia constraints require that the core is small, such a core would at least behave as a magnetohydrodynamic fluid even at the present slow rotation rates[10]. There are, however, many difficulties[11] and here we consider whether an early hot outside, cold inside Moon, which evolved into the present cold outside, hot inside Moon, could quantitatively account for the evidence of an ancient magnetic field.

Origin of early magnetisation

If the Moon accreted cold then any metallic iron which was present may have acquired a remanent magnetisation from any of several mechanisms, provided there was an ambient field[12]. We consider a mechanism in which the Moon was magnetised by an external steady field, thus acquiring isothermal remanent magnetisation (IRM). If the Moon were uniformly magnetised, it would need to have had a dipole moment of about 10^{23} gauss cm^3 to give an ancient surface field of 2,000 gamma (γ) which is typical of several palaeointensity studies, although a much higher value has been reported[13–16]. This is well above the present value of less than 10^{20} gauss cm^3 (ref. 17). We have measured the IRM of iron-bearing, igneous rocks from the Moon,

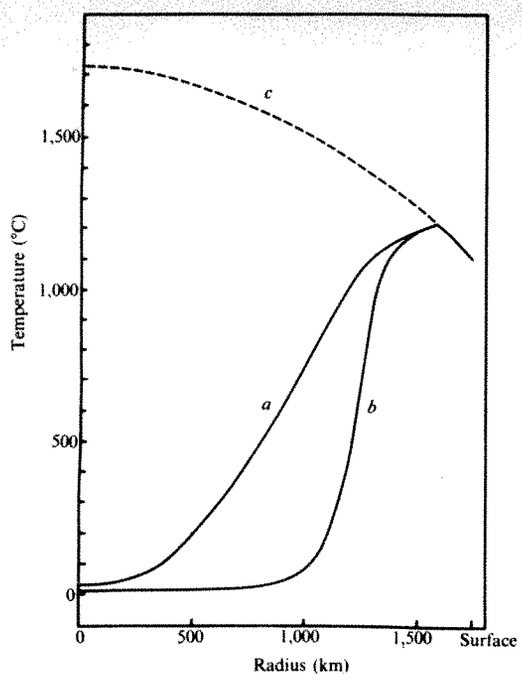

Fig. 1 Initial temperature distributions for an accreting Moon. The modified version permits the bulk of the Moon to remain below the Curie point of iron until 3.2×10^9 yr ago. *a*, Mizutani; *b*, modified; *c*, solidus.

which best represent the magnetic behaviour of rocks at depth These samples generally have a high proportion of multidomain (coarse) iron and readily acquire a soft IRM in a weak field. On the other hand, the soils are rich in superparamagnetic (~300Å) iron, and the breccias range from superparamagnetic, unwelded samples, to multidomain, highly recrystallised samples. Typically, surface igneous rocks, which contain about 0.05 weight % metallic iron, acquire an IRM of about 3×10^{-5} e.m.u. g^{-1} in a 10 oersted field[18]. By extrapolation, similar material with about 3% by weight of iron would acquire an IRM of about 2×10^{-3} e.m.u. g^{-1} in a field of 10 oersted, giving the required dipole moment. Large variations in the distribution of iron in the Moon, both laterally and vertically, could give rise to significant local variations in the field; perhaps accounting in part for the diversity of palaeointensity determinations.

Table 1 Parameter values used for lunar thermal models[1-6,28]

Model	Mass ratios Th/U	K/U	Source	Heat generation ($\times$ 317 erg g^{-1} s^{-1})	Decay constant ($\times$ 3.17 $\times$ 10^{-18} s^{-1})
Chondritic	4.15	80,000	U^{238}	2.97	1.54
Terrestrial	3.84	10,000	U^{235}	18.0	9.71
Lunar	4.00	2,000	Th^{232}	0.82	0.499
			K^{40}	0.94	5.5

Heat capacity, $cp = 10^7$ erg g^{-1} ° C^{-1}; heat of fusion, $hf = 4.0 \times 10^9$ erg g^{-1}; density, $\rho = 3.34$ g cm^{-3}; index of refraction, $n = 1.7$; opacity, $e = 100$ cm^{-1}; Stefan-Boltzmann constant, $s = 5.669 \times 10^{-5}$ erg cm^{-2} K^{-4} s^{-1}

Two questions need to be answered. First, what is the origin of the magnetising field? Second, once the Moon had become magnetised by an isothermal process could the memory have been retained until the termination of igneous activity about 3.2×10^9 yr ago. There is no definitive answer to the first question, because there are no clear records of planetary fields predating those frozen into the lunar rocks. It is, however, possible to speculate either that such fields existed early in the history of the Solar System in connection with local plasma instabilities, or that a close approach of the Moon to the Earth could have increased the turbulent motions in the Earth's core to the point at which the Earth's dynamo was much stronger than at present[13]. In either case a field of the order of 10 oersted needs to have existed, at least momentarily, some time after the bulk of the Moon had accreted.

The question of the time decay of IRM is hard to answer but extrapolation of the decay rate of IRM acquired in the laboratory in multidomain, iron-bearing rocks shows that the decay coefficient is very small[20].

Models of lunar evolution

A successful evolutionary model which will permit the Moon to retain an IRM long enough to provide a magnetic field in which the mare basalts would cool must also satisfy the following constraints.

(i) Early melting of the near surface regions, so that a crust may form by differentiation.

(ii) At least local melting in the near surface region between 3.2 and 4.0×10^9 yr ago, so as to provide a source for the mare basalts[21].

(iii) Cessation of this near surface melting no later than 3.2×10^9 yr ago because, first, there seems to have been no igneous activity after this time, and, second, the outer portion of the Moon must have cooled sufficiently to support the mascons which formed probably no later than this date.

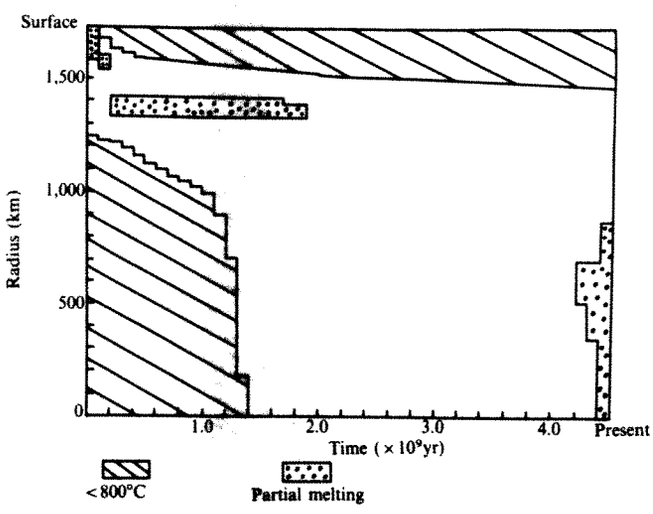

Fig. 2 Graph of radius against time showing the regions of partial melting and those regions which have temperatures below the Curie point of iron. For this model, the present-day surface heat flow is 23 erg cm^{-2} s^{-1}.

(iv) Much of the volume of the Moon must have been below 770° C (the Curie point) until 3.2×10^9 yr ago so as not to remove the magnetising field.

(v) A present day partially (or totally) molten core with a radius not exceeding 850 km, as suggested by seismic data[7-9] and predicted by Gast and Giuli[24].

(vi) The present day heat flow should lie in the range 20–30 erg cm^{-2} s^{-1} to be consistent with the Apollo 15 and 17 results[25].

In addition we have assumed that the Moon was of uniform composition at the time of accretion. We recognise this as an *ad hoc* assumption but chose to retain this simplicity until the model required otherwise. The basic initial temperature model (Fig. 1*a*) comes from Mizutani[23] and is close to his 'most likely' model, with $N_0 = 10^{-8}$ g cm^{-3} and $C = 3$ m s^{-1}, where N_0 is the

initial cloud concentration and C is the most probable particle speed for accretion. Using this particular model, the outer 150 km would be molten at the end of accretion and thus the Moon could have differentiated to give the present day crust.

The thermal history of the Moon was calculated using numerical methods but the analytical method was restricted to conduction solutions. The calculation is inherently nonlinear, because of the inclusion of a radiative term dependent upon temperature in the thermal conductivity. Details of the calculations will be published elsewhere.

The thermal conductivity used was $K + (16n^2s/3e)T^3$ where K is the lattice conductivity, T is the temperature and e the opacity (other terms are defined in Table 1). The parameters K and e are known from laboratory experiments to depend on temperature but in the range encountered in the models used here this is only a small effect[26]. The value of K was allowed to range from 0.1×10^5 to 10×10^5 erg cm^{-1} s^{-1} ° C^{-1}. The parameters used for n and e are given in Table 1.

Radioactive abundance ratios characteristic of lunar terrestrial and chondritic materials were used (Table 1). Our model does not account for any ratio changing upon fractionation. The values of uranium concentration were allowed to vary from 0.5×10^{-8} g g^{-1} to 10×10^{-8} g g^{-1}.

The calculations accounted for partial melting, total melting, differentiation of heat sources, resolidification and remelting, and convection of heat in fluid zones. The melting point criterion was that of Ringwood and Essene[27].

The Mizutani version (Fig. 1*a*) produced a Moon which was well above the Curie temperature for most of its history. We therefore arbitrarily reduced the interior temperature until suitable models could be found (Fig. 1*b*). This model implies that the outer part of the Moon accreted somewhat more rapidly, and/or the inner part more slowly than is implied by Mizutani's model. Alternatively it means that the initial temperature was less than 0° C.

The models which satisfied the constraints were almost unique in the choice of conductivity and uranium concentration. This is because of the conflicting requirements that the interior of the Moon remain cold enough not to destroy its IRM during approximately the first 10^9 yr, but that it should heat up rapidly enough during the next 3×10^9 yr so as to produce a partially molten interior out to the present radius of ~850 km. Only a very delicate balance between the thermal conductivity and uranium concentration could satisfy both constraints under the general assumption of an initially chemically and physically uniform Moon. If we relax the constraint of an early cold Moon, most of which is below the Curie point, until about 3.2×10^9 yr ago, models which satisfy the remaining five constraints can be produced. The uranium concentration is about 50 parts in 10^9, the thermal conductivity about 9×10^5 erg cm^{-1} s^{-1} ° C^{-1} and the heat flow value about 22 erg cm^{-2} s^{-1}.

The thermal conductivities tend to be slightly higher than typical experimental values for representative lunar analogues[28]. The uranium abundances are, however, very close to the average values commonly quoted for terrestrial, chondritic and lunar materials[1-6]. Finally, the indicated heat flow values all fall within the range of values determined by the lunar heat flow experiments[25]. Figure 2 illustrates that most of the Moon must remain below 770° C until about 3.2×10^9 yr ago.

We may now construct a sequence of events for the magnetic history of the Moon (Fig. 3). Initially the Moon was magnetised by a field of the order of 10 oersted when most of it was below the Curie point. The differentiation of the crust then occurred, concentrating a crust rich in anorthosite. Next, soils and breccia flows were formed primarily as a result of impacts and/or volcanic activity which enriched them in metallic iron. At or about the same time the mare basalts were formed. Finally, about 3.2×10^9 yr ago, the interior of the Moon heated up sufficiently to destroy the internal IRM, leaving only a magnetised crust. The crust could, in principle, still carry a dipole moment. The fact that none is observed could be because the Moon may have been magnetised after the crust was formed. It may also be because the crust is formed of material such as anorthosites or anorthositic gabbros which carry only a weak magnetic remanence[18]. Subsequent impacting may also have randomised directions in the crust.

We acknowledge discussions with W. Gose, G. W. Pearce and J. Arkani-Hamed. This work was partially supported by the Lunar Science Institute operated by the University Space Research Association. One of us (H.N.S.) acknowledges support from the National Research Council of Canada.

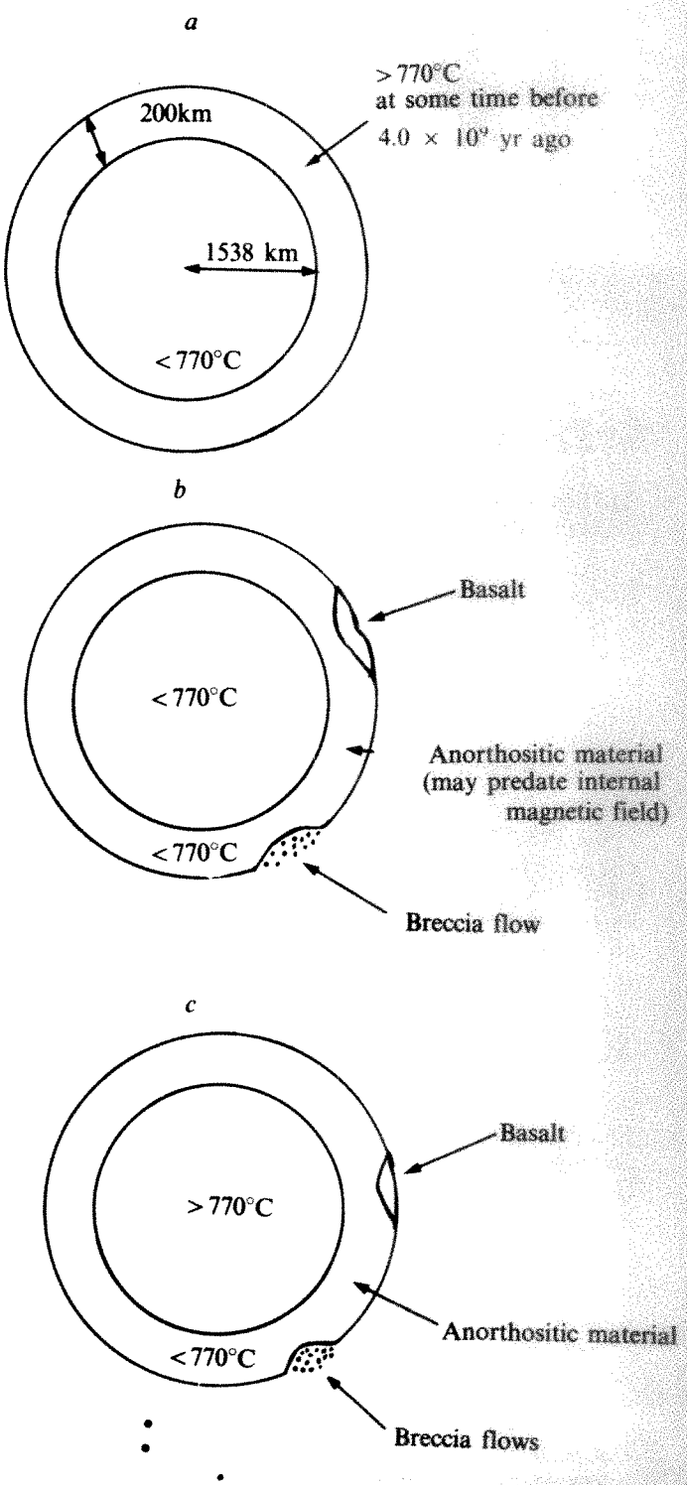

Fig 3. Schematic representation of the stages in the evolution of a cold Moon. The model presented here permits the magnetic, thermal, mean density, and moment of inertia constraints to be satisfied: *a*, before 4.0×10^9 yr ago; *b*, $4.0 - 3.2 \times 10^9$ yr ago; *c*, 3.2×10^9 yr ago.

Gravitational deflection of polarised radiation

Martin Harwit & R. V. E. Lovelace

Brian Dennison & David L. Jauncey
Center for Radiophysics and Space Research, Cornell University and National Astronomy and Ionosphere Center

John Broderick
National Astronomy and Ionosphere Center

An upper limit is determined for the difference in the deflection of beams of orthogonally polarised radiation passing through the Sun's gravitational field. A null result is anticipated by present theories of gravitation but this prediction has never been tested.

PRESENT theories of gravitation tacitly assume that two orthogonally polarised beams of radiation will be deflected by equal amounts on passing near the Sun's limb. This hypothesis has never been tested, even though available techniques should permit measurement of a differential deflection up to 10^4 times smaller than the total deflection suffered by the radiation.

The equivalence principle predicts that orthogonally polarised radiation should show no differences in deflection by the Sun. An observer falling freely into the Sun should see all beams of radiation following straight trajectories at his own location. If radiation polarised in one sense were deflected at a rate different from oppositely polarised radiation, then initially coincident beams of mixed radiation would separate into two beams that curve away from each other. At least radiation polarised in one of the two senses would no longer appear to propagate along a straight line for a freely falling observer.

Most theories of gravitation incorporate the equivalence principle, at least in the limit of geometrical optics and weak fields, and we would expect gravitationally deflected radiation to follow paths unaffected by the state of polarisation. But we can think of situations in which polarisation must play an important role. One particularly limiting case, pointed out to us by Dr Stuart Shapiro, involves maximally rotating black holes.

Such a black hole is incapable of absorbing long wavelength radiation approaching along the hole's axis of rotation if the radiation is circularly polarised with spin angular momentum parallel to the angular momentum of the hole. This is because absorption of this radiation would endow the hole with excessive angular momentum and would add too little rest mass to the hole. As a result this radiation is not absorbed at all. In contrast, oppositely polarised radiation is readily absorbed since it merely tends to slow down the rotation of the black hole.

Although this picture is quite extreme, we would expect some measure of differentiation between left and right polarised radiation whenever long wavelength, circularly polarised radiation is scattered or absorbed by a rapidly rotating compact object (ref. 1 predicts a small Faraday-like rotation of the polarisation vector near a rapidly rotating mass). For shorter wavelengths, and larger, less rapidly rotating objects, these effects diminish, so that we again retrieve the result that gravitational effects should clearly distinguish different states of polarisation only in the diffraction limit, namely where the wavelength becomes comparable to the Schwarzschild or Kerr radius of the massive object.

We may eventually hope to make wavelength and polarisation-dependent observations that show such gravitational effects in eclipses of compact binary stars. But for the moment we have been attempting to establish, by observations, whether or not orthogonally polarised—linearly or circularly polarised—components of radiation are deflected by identical amounts in the Sun's gravitational field. Here we are clearly in the classical geometrical optics limit, and we are dealing with very low angular momentum in the deflecting mass. We would therefore expect no measurable difference in the deflection of orthogonally polarised radiation components.

Using very long baseline radio interferometry, this null result can, in principle, be determined with very high accuracy. The principal limitations are provided by the length of the available

baseline and Faraday rotation in the solar corona.

It is well known that the orthogonal polarisation components of a radio wave may be affected differently in propagation through a magnetised plasma. Faraday rotation of the plane of polarisation and plasma birefringence could obscure any differential gravitational deflection. For the present experiment the interplanetary plasma is expected to give the largest effect due to the Faraday rotation. We calculated, however, that even this Faraday rotation is negligible for solar elongations larger than $5R_\odot$. No significant plasma effects are expected from the ionosphere. Very long baseline interferometry, using a transcontinental baseline, offers a potential accuracy of almost 10^{-4} arc s at 8 GHz—of the order of one part in 10^4 of the total deflection.

If any effect is present, then the position of a small diameter radio source when viewed in one polarisation will be displaced from the position viewed with the orthogonal polarisation. This will show up as a slight change in the interferometer fringe rate between the two polarisation channels, an effect analogous to the beating of the separate components for a multicomponent source when viewed with a single polarisation.

As we are only searching for a relative displacement, the quantity to be measured is the relative phase difference between the orthogonal polarisations from the same radio source. This is independent of the local oscillator phase at each site provided that the same signal is applied to the two receivers at each radio telescope. In this way the full resolution of the interferometer can be realised.

Effectively, the observations search for an apparent splitting of the source, into orthogonally polarised components, as it approaches the Sun. Such a split can be detected far more readily than an absolute deflection relative to another radio source placed some degrees away in the sky. This second situation is the one that describes measurements of the normal deflection of radiation by the Sun. There the total change in angular separation of the sources 3C273 and 3C279 is measured to an accuracy of a few parts per million to arrive at a total deflection known to an accuracy of a few per cent.

Observations

The observations were carried out with the Green Bank-Owens Valley baseline on September 30 (day 274) and October 4 (day 278), 1972, when the radiation from these sources passes near the solar limb. The baseline is 3,900 km (10^8 wavelengths), and is nearly east–west. The Mark II VLBI tape recording system was used. The observations in Green Bank were with the Howard E. Tatel 85-foot (85-1) radiotelescope of the National Radio Astronomy Observatory (NRAO), and the frequency standard was obtained from the hydrogen maser installed at the 140-foot dish. At the Owens Valley Radio Observatory (OVRO) both A and B 90-foot radiotelescopes were used, and a Sulzer crystal oscillator, phase locked to a Hewlett Packard 5065A frequency standard, was used. Synchronisation was obtained from Loran C radio transmissions at NRAO and from the Goldstone Tracking Station at OVRO.

Different polarisations were sampled by switching 85-1 between left and right circular polarisation (LCP and RCP) every 2 s, while switching between antennae A and B at OVRO every 1 s. Antennae A and B had linearly polarised feeds, which were preset to be orthogonal. Hence in a period of 4s all four combinations of polarisation were sampled. As the coherence time of the rubidium-driven Sulzer oscillator is longer than the switching rate, relative phases between the different polarisations were easily obtained. The preliminary reduction was accomplished with the NRAO Mark II processor, and the fringes corresponding to the various polarisations were sorted by computer and combined into their respective groups. The VLBI interferometer was sensitive to dual sidebands of 2 MHz width centred at 8,075 and 8,095 MHz. Each sideband was processed separately.

In Fig. 1 the relative positions of 3C273, 3C279, and the Sun during the experiment are shown. Unfortunately, the signal-to-noise ratio for 3C279 was too small to allow us to make any convincing measurements of relative phase, although weak fringes were detected. This is due to the weak correlated flux[2] in 3C279 ($\leqslant 3$ f.u.). The correlated flux in 3C273 was about 12 f.u., and the relative phases between orthogonal circular polarisations were easily measured. On the two days of observations 3C273 was 5.0° and 7.8° from the Sun.

We have not been able to determine the phase difference in orthogonal linear polarisations due to a discrepancy, as yet not understood, in fringe rate between antennae A and B (although the change in baseline was properly taken into account). But two independent determinations of phase differences in the circular polarisations were obtained from separate analyses of the fringes produced by correlating antenna 85-1 with antenna A, and by correlating 85-1 with antenna B. For a source separated into two components, with angular separation, $\Delta\theta$, at position angle A, the fringe phase difference is $\Delta\Phi = \Delta\theta\,[(B_x\sin A - B_y\sin\delta\cos A)\sin H - (B_x\sin\delta\cos A + B_y\sin A)\cos H + B_z\cos\delta\cos A] + \text{constant}$

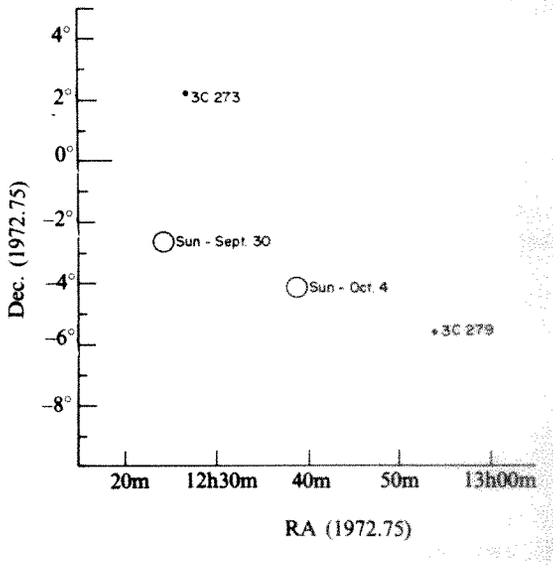

Fig. 1 Positions of 3C273, 3C279 and the Sun on the observing days.

where H is the hour angle, (α, δ) is the source position, and B_x, B_y, and B_z are the baseline components in wavelengths. Symmetry considerations lead us to expect that any separation of circular polarisation components will be perpendicular to the radial direction. Thus the position angle of the splitting, A, is orthogonal to the position angle from the Sun to the radio source. Phase differences between the orthogonal circular polarisations were calculated for scans of 15 min during the observing sessions. The data shown in Fig. 2 were fitted to the equation by the method of least squares. This was done for the B antenna experiment on October 4 and for the A antenna experiment on both days. The B antenna was not functioning properly on the first observing day. The phase differences for the upper and lower sidebands have been kept separate, since the exact times of relative phase determination, and the values of B_x, B_y and B_z differ slightly. Also the data from both days in the A antenna experiment were, in one case, taken together in the same least squares fit by arbitrarily assuming the splitting, $\Delta\theta$, to have a $1/r$ dependence on solar elongation. None of these least squares fits yielded significant splitting above the error level. Upper limits for all of these cases were obtained by calculating χ^2 for assumed values of $\Delta\theta$. The upper limits of the splitting, corresponding to the 95% confidence level are given in Table 1. It is noted that by assuming a yet stronger radial dependence

Table 1 Upper limits to the polarisation splitting

Polarisation	Observing days used	Data used	Solar elongation ($R_\odot$)	Splitting upper limits (95% confidence) Tangential $\Delta\theta$ clockwise (10^{-3} arc s)	Tangential $\Delta\theta$ counter-clockwise (10^{-3} arc s)	Radial $\Delta\theta$in (10^{-3} arc s)	Radial $\Delta\theta$ out (10^{-3} arc s)
Circular	278	Even	7.8	2.4	1.9	4.1	3.3
Circular	278	Odd	7.8	2.2	0.5	—	3.0
Circular	274	Even	5.0	27	25	336	467
Circular	274 and 278 Dependence on R neglected	Even	7.8	2.1	1.5	3.7	3.5
Circular	274 and 278 $1/R$ dependence assumed	Even	7.8	1.6	1.1	3.5	3.4
Linear	Change of polarisation technique		4 to 6			2.5×10^{-4}	2.5×10^{-4}
Circular	Faraday rotation technique		7			2.1×10^{-3}	2.1×10^{-3}

Clockwise tangential splitting is defined as that seen by an observer in which right circular polarisation appears rotated clockwise about the Sun away from left circular polarisation. In outward radial splitting right circular polarisation appears at greater solar elongation than left circular polarisation. The 'even' data are the result of correlating antennae A and 85-1, and the 'odd' data from correlating antennae B and 85-1.

than $1/r$, smaller upper limits are obtained since additional weight is effectively put on the data obtained at smaller solar elongations.

Results for circular polarisation

Symmetry considerations suggest that two circularly polarised radiation components could at best be split along a line perpendicular to the direction of the (non-rotating) deflecting mass.

As shown in Table 1, our observations set an upper limit of roughly 0.002 arc s for the difference in the deflection of the two circularly polarised components along a direction perpendicular to the solar radius vector. Along the direction of the radius vector, our upper limit is approximately 0.0035 arc s.

These upper limits are to be compared to a total gravitational deflection of ~0.2 arc s for radiation passing at these distances from the Sun.

Linearly polarised radiation

Radiation reaching us from a source that lies beyond the Sun can be decomposed into two orthogonally linearly polarised radiation components, with one polarised in a direction parallel to the radius vector from the Sun and the other polarised along a tangential direction. If these two components are not deflected identically by the Sun's gravitational field, it can be because one of the two components is slowed down more on approaching the Sun. This produces splitting along the radial direction. This situation is consistent with symmetry considerations. The component with the slower velocity is deflected more strongly, since its wavefront is retarded more strongly in the Sun's vicinity.

One way of measuring the time delay due to such a differential reduction in the velocity of propagation of the wave is to search for phase delays in the propagation of the two components. If the radially polarised component R and the tangentially polarised component T are equally strong, and the source is initially linearly polarised in a direction at 45° to the solar radius vector, then any difference in the propagation time past the Sun would make itself felt as a transition toward elliptical polarisation. If the difference in propagation time became as large as one quarter of a cycle, the initially linearly polarised wave would become purely circularly polarised. At a delay of half a cycle the wave would again be linearly polarised, but at an angle 90° removed from the initial direction (Fig. 3).

Thereafter there would be a second stage of elliptical polarisation, culminating in circular polarisation for a delay of 3/4 cycle. But the sense of circular polarisation between delays of 0 and 1/2 cycle is opposite to that between 1/2 and 1 cycle. A delay by a full cycle gives a wave linearly polarised in the initial sense, as emitted at the source. The intermediate state of elliptical or circularly polarised radiation would be right handed or left handed depending on which of the two components—the radial or the tangential—was propagated less rapidly.

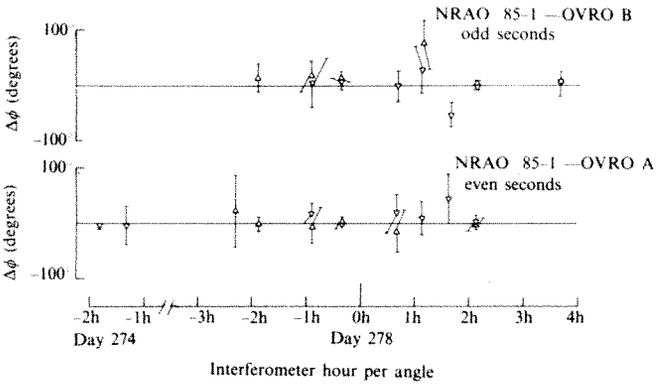

Fig. 2 Relative fringe phase between left and right circular polarisation for 3C273 is shown as a function of hour angle. Each point corresponds to approximately 15 min of observing. Upper (△) and lower (▽) sidebands are plotted separately. The arbitrary additive phase constant has been removed.

Observations carried out by Stelzried *et al.* in 1968 on the plane polarised carrier wave of 2.29 GHz (13 cm) transmitted by the solar orbiting spacecraft Pioneer 6 followed the source to within about $4R_\odot$ from the Sun. Although the polarisation emitted by the spacecraft was almost purely tangential to the solar radius vector[3], strong Faraday rotation was observed when the transmitted beam passed within about $6R_\odot$ from the Sun. By $4R_\odot$, where the signal became too difficult to follow, the polarisation angle had rotated from 90°—perpendicular to the ecliptic plane—through 0° and on to −45°.

It is virtually certain that at some time during this period Faraday rotation would have produced a polarisation angle of ~45° near the ray's closest point of approach to the Sun. Nevertheless, no ellipticity was detected, although the instrumental resolution of power axial ratio was ~0.1. This implies a maximum phase shift between the two linearly polarised components amounting to much less than 1 cm in separation. In contrast, a wave passing within $4–6R_\odot$ of the Sun is[4] delayed ~ 10^6 cm, indicating that the time delay and its associated bending should be identical for both linear polarisations to within one part in ~10^6.

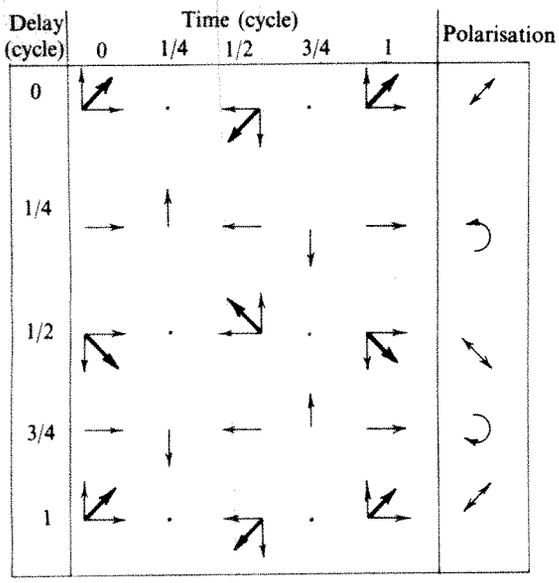

Fig. 3 The polarisation of a wave formed by the superposition of two orthogonal linearly polarised waves. The resulting polarisation depends on the phase relationship or delay between the two waves.

Beyond $7R_{\odot}$, where Faraday rotation effects seem to be negligible, the Pioneer 6 experiment also gives an upper limit on the time delay difference for orthogonally polarised circular components. This appears to be less than about one part in 10^5 of the total effect.

Space probe experiments of this type in the X band or at higher frequency could provide more stringent results.

The future

We have been able to place upper bounds on the possible difference in the deflection of orthogonally polarised radiation components passing through the Sun's gravitational field. Although these bounds are already quite stringent, order of magnitude improvements can be expected within the next few years by straightforward improvements in the techniques described here. Without extensive innovations, we may expect sensitivities to reach one part in 10^4 to 10^6 of the total gravitational deflection. Even a null result obtained in such observations should be a useful constraint for the construction of theories of gravitation.

We mentioned earlier that there should exist differential deflection effects that depend not only on polarisation but also on wavelength. These effects may be too small to measure in the deflection of radiation passing by the Sun, but we may hope to obtain significant results in astronomical observations involving eclipses of compact binary stars.

Very long baseline interferometer observations such as ours may also eventually have application to the polarisation structure of compact radio sources. Indeed one model of expanding doubles predicts that each component will have weak circular polarisation orthogonal to the other (unpublished work of R. H. Sanders). For our purposes polarisation structure can be separated from any gravitational effects by observing each source at different solar elongations. The observed lack of circular polarisation[5] in 3C273 implies that any structural features that could be detected should be much smaller than 0.001 arc s.

This work was partially supported by the National Science Foundation and by the Research Corporation. D. B. Shaffer helped in the observations at OVRO and we also thank T. Gold, E. E. Salpeter, S. Shapiro and R. V. Wagoner for discussions and B. G. Clark, S. Teukolski and C. Will for comments. The reduction of our data was helped by discussions with J. Burch, B. G. Clark, H. Hardebeck, P. Hemmenway, K. I. Kellermann, B. Rayhrer and R. Schillizzi. The National Radio Astronomy Observatory is operated by Associated Universities, Inc., under contract with the National Science Foundation.

Note added in proof:

After this paper had been submitted, our attention was drawn to a paper by Mashhoan[6], in which the questions discussed here are placed into a general relativistic framework. The author derives several important results that help in predicting the size of expected effects.

Dust in the head of Comet Kohoutek

We have been making photographic observations of Comet Kohoutek (1973f) at the observatory of Izaña, Tenerife, with the aim of assaying the dust content of the tail. We have taken many photographs on various films and with various filters; having enlarged and printed some of the negatives we have noticed on many of them a straight dark streak running away from the head for a distance of about $2\frac{1}{2}$ arc deg. The streak is to be seen on exposures made on 1974 January 9, 10, 11 and 12 on Kodak Tri-X Pan, RAR 2495 and Eastman Kodak High Speed Infra-red (HIE-135) emulsions and with focal lengths of 85, 135 and 225 mm (Fig. 1).

We conjectured that the streak might be the shadow of the head of the comet cast on to the tail and so we computed the position angle of the Sun with respect to the comet head. We found that it agreed with the streak direction to within our limits of accuracy of measurement (about 10 arc min). We assumed that our objectives were free from distortion and that the photographs represented a stereographic projection of the celestial sphere centred on the comet's head.

If this explanation of the streak is accepted, several interesting conclusions follow:

(1) The opaque region casting the shadow has a diameter

of about 4×10^7 m (25,000 miles). This follows from the observed length of the streak and the known distance of the comet from the Earth at the time. It does not follow, of course, that there is a solid nucleus of this diameter since even sparse dust in sufficient depth can cause enough opacity.

(2) The opacity is caused by dust, not gas, and this dust has a low albedo, otherwise the comet would have been much brighter.

(3) If we assume as usual, that the particle size distribution obeys a power law $n(a) = ka^{-p}$ with $p = 3$ for small particles[1] and 4 for larger ones, and that the space density of particles varies inversely as the square of the distance from the centre of mass (or nucleus if there is a nucleus) as required by a simple continuity equation, then it is possible to calculate what we might call the 'opacity radius'—the distance from the centre of mass at which a light beam must pass in order to be attenuated by a factor 1/e. Alternatively if this radius is known then the mass enclosed within a sphere of this radius can be computed. A simple formula can be derived: $M = (2/3)a\rho D^2$, where D is the opacity radius, a is the upper limit of particle radius and ρ is the material density of the particles. Here we have apparently $D = 2 \times 10^7$ m and $a = 10^{-4}$ m (ref. 2) since the power law seems to break down for large particles; and if $\rho = 3$ then $M = 8 \times 10^{13}$ kg; $\rho = 8$ gives $M = 2 \times 10^{14}$ kg.

Fig. 1 Comet 1973f at 1945 on 1974 January 9. In white light, exposure 80 s at f/2 on Kodak Tri-X Pan film. The head had a magnitude of +3.5 at this time. The three bright stars at the top of the field are (from left to right): 46 Capricorni, ξ Aquarii, β Aquari.

These figures agree well with the estimates made by Whipple[3] for the total mass of a comet and suggest the possibility that the whole mass may be contained in the dust cloud. There would be ample surface area, 3×10^{15} m^2 if the particles are spherical, more if they are not, for the adsorption of gases and sufficient opacity to prevent them from volatilising too quickly.

We thank the Royal Society for financial support and Professor Francisco Sanchez Martinez of the University of La Laguna for the use of his facilities at the Observatorio del Teide at Izaña.

Atmosphere of Mercury

The recently released news concerning the possible atmosphere surrounding Mercury seems to have taken the astronomical community by surprise. It had generally been expected that because of the high temperatures (of the order of 450 K) existing there and also because of the low surface gravity, any atmosphere originally present, or any released from subsequent events on the surface would quickly evaporate since the random thermal speed of the atoms would be greater than the escape velocity. If V_E is the escape velocity from Mercury, ρ_A the density of its atmosphere and A the surface area, then a simple computation indicates[1,2] that the rate of mass loss from this atmosphere is

$$\frac{dM}{dt} = \frac{A\rho_A}{\sqrt{(\beta\pi)}} [1 + \beta V_E^2] \exp(\beta V_E^2)$$

where $\beta = m/2kT$, k being Boltzmann's constant and m the atomic mass. All this ignores the solar wind which carries mass into the atmosphere. In reality the problem becomes a boundary layer problem in which the magnetic field of Mercury plays a part, but we can see simply that the main effect is to generate an atmosphere. If the wind has a density ρ_W and a velocity V_W, then it adds matter to Mercury at the rate

$$\frac{dM}{dt} = AV_W \rho_W$$

and the stead state situation is given when

$$V_W \rho_W = \frac{\rho_A}{\sqrt{(\pi \beta)}} [1 + \beta V_E^2] \exp(-\beta V_E^2)$$

or

$$\frac{\rho_A}{\rho_W} = \left[\frac{\sqrt{(\pi\beta)} V_W \exp(\beta V_E^2)}{[1 + \beta V_E^2]}\right]$$

Inserting the appropriate numerical values, $\beta \approx 10^{-11}$, $V_E^2 \approx 2 \times 10^{10}$, and $V_W \approx 10^8$ (all in c.g.s. units gives)

$$\frac{\rho_A}{\rho_W} = 600$$

There should therefore be a very tenuous atmosphere, basically composed of hydrogen being maintained in this way. Any helium and argon released by radioactivity would become trapped in this atmosphere and should be detected.

If the atmosphere is signficantly denser than given above, it implies that volcanic activity or some such gas generating process must be active now.

Existence of two groups in thermoluminescence of meteorites

The thermoluminescence (TL) properties of meteorites[1-4] may be applicable to the determination of exposure age, terrestrial age, thermal gradients, radiation history and preatmospheric shape. In an attempt to apply TL to the determination of terrestrial age we have discovered that meteorites can be divided into two groups, the existence of which is relevant to several of the applications.

Our apparatus consists of a molybdenum strip heated electrically at $5 \pm 0.05°$ C s^{-1} by an electronic control unit. The light emitted by 10 mg of 50 μm sieved powder placed on a defined area of the strip is measured by a cooled and shielded 9635B EMI photomultiplier tube. The amplified signal is plotted automatically against temperature. The resulting 'glow curve' has two peaks, one at about 200° C (LT) and one at about 350° C (HT).

Table 1 Details of meteorites of known terrestrial age

Meteorite	Terrestrial age (yr)	BM no. (if applicable)	Class	Thermoluminescence group
Barwell	8		L6	Low
Bruderheim	13		L6	Low
Khanpur	21		LL5	Low
Mangwendi	39		LL6	Low
Olivenza	49		LL5	Low
Saratov	55	BM1956, 169	L4	High
Crumlin	71	BM86115	L5	Low
Gambat	76	BM83864	L6	Low
Jelica	83		LL6	Low
Soko Banja	96		LL4	High
Tennasilm	101	BM1913, 218	L4	High
Butsura	112	BM34795	H6	High
Dhurmsala	113		LL6	Low
Aldsworth	138	BM61308	LL5	Low
Durala	158	BM32097	L6	High
Limerick	160		H5	Low
Wold Cottage	178	BM1073	L6	High
Mauerkirchen	205	BM19967	L6	High
Ogi	232	BM55256	H6	High

We recorded the glow curves of nineteen meteorites that were seen to fall and are therefore of accurately known terrestrial age (Table 1). Two groups were immediately apparent; one in which LT falls below HT in about 100 yr after fall, and one in which it takes several hundred years for this to occur. Although the two groups are evident by visual inspection of the glow curves they are more obvious in Fig. 1, a plot of $\log_e$ (peak height ratio, LT/HT) against the terrestrial age of the meteorite. The low retentivity group, in which LT is fading fastest, shows much scatter from the line but the high group shows surprisingly little. The cause of the scatter is probably small initial differences in the TL of the meteorites, different thermal histories since the decay is temperature sensitive and, in the case of the low group, varying degrees of shock.

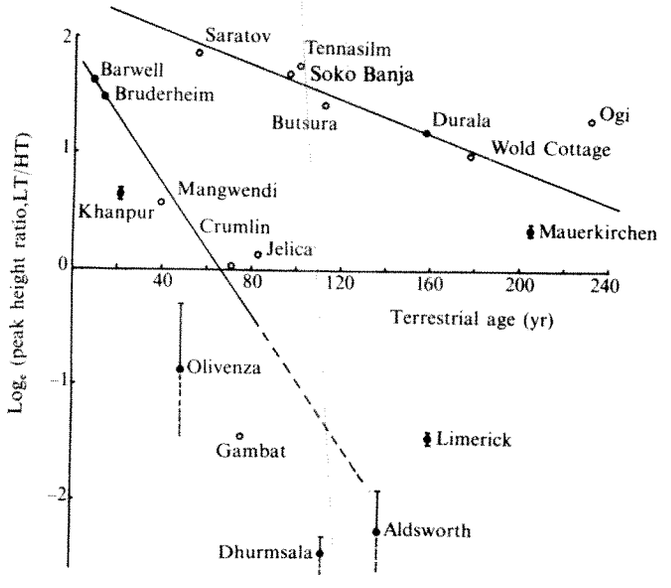

Fig. 1 Natural logarithm of the peak height ratio (LT/HT) as a function of terrestrial age, for meteorites of known terrestrial age.

To confirm that meteorites in the low retentivity group are fading faster than meteorites in the high retentivity group, the mean life (time to fall to 1/e) of LT in six meteorites was determined. We heated powder from three high and three low group meteorites in the dark at 120° C for various periods up to 70 h. Heating was done in an Abderhalden drying pistol surrounded by refluxing tetrachloroethylene. The results are shown in Fig. 2. Although the curves are not exponential, and the results must be treated as approximate, it is clear that the two groups are due to different mean lives of LT in the luminescent material. The mean life, τ, at room temperature can be calculated from

$$\tau(300\text{K}) = \tau(393\text{K}) \exp[(E/k300) - (E/k393)]$$

where E, the energy of the peak, can be found by the initial rise method and k is the Boltzman constant[5]. For the low retentivity group the mean life at room temperature is 6–8 yr and for the high group 45–55 yr.

We have not been able to determine with certainty the reason for the two groups but suspect that it is related to shock. Both metamorphism and shock change the nature of the luminescent feldspar, shock producing maskelynite and metamorphism causing recrystallisation. Chemical–petrological groups assigned on the extent of metamorphism[6] show no correlation

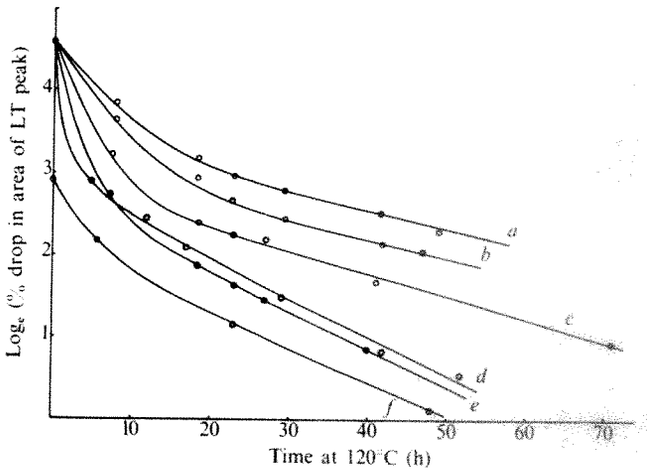

Fig. 2 Isothermal annealing curves for three high and three low retentivity meteorites. The ordinate is the natural logarithm of the percentage drop in the area under LT. Overlap has been allowed for where necessary and the curve for Jelica has been displaced vertically downwards for clarity. *a*, Wold Cottage (50–54 h); *b*, Saratov (50–55 h); *c*, Tennasilm (50–55 h); *d* Barwell (28–34 h); *e*, Bruderheim (26–34 h); *f*, Jelica (28–34 h). The numerical values are estimated for the mean lives at 120°C.

with the TL groups of the meteorites, inferring that metamorphism does not govern TL group membership. Shock is known to reduce TL intensity, however, and we have reason to believe that it also reduces the mean life of LT. Most of the members of the low group have been shocked or are breccias (R. Hutchison, personal communication). Olivenza and Barwell are anomalous in this respect, as is Soko Banja which is in the high group but is a breccia. Shock may also explain the scatter in the low group line in Fig. 1 since it can occur with various degrees of severity.

We thank Mr W. Prachyabrued (University of Birmingham) and Dr R. Hutchison (British Museum, Natural History) for discussions and the latter for supplying the ten BM specimens.

Fission track dating of a vitric tuff from East Rudolf, North Kenya

ACCURATE dating of the Plio–Pleistocene sedimentary sequence in the East Rudolf basin of northern Kenya is urgently required to provide a time framework for the hominoid[1,2], archaeological[3,4] and other[5,6] important finds in the area. A sequence of water-lain tuff horizons are intercalated with lacustrine, deltaic and fluviatile sediments[7] and if a number of these tuffs can be dated with sufficient accuracy they could provide both the primary geochronological framework required and, by establishing correlations between East Rudolf sections and the world-wide geomagnetic reversal time scale, enable palaeomagnetic dating to be applied to those parts of the stratigraphy lying between the dated tuff horizons.

^{40}Argon/^{39}Argon age spectrum analysis by Fitch and Miller[8] has provided a firm date of 2.61±0.26 Myr for the prominent KBS Tuff horizon that occurs near the middle of the sedimentary sequence. This date is compatible with the probable age ranges of the sediments suggested by palaeontological correlation with dated sequences elsewhere in East Africa[5] and with the initial findings of the palaeomagnetic reversal study[9]. Further work by Fitch and Miller[10] indicates that straightforward K/Ar or ^{40}Argon/^{39}Argon dating of the East Rudolf tuff horizons is complicated by episodes of enhanced groundwater metasomatism which probably resulted from the periodic release of volcanic heat and/or hot fluids in the area. They suggest that although the East Rudolf succession contains clear evidence of a sequence of local, explosive ignimbritic eruptions over the period 5.0 to 0.5 Myr, in some parts of the sedimentary basin metasomatism has disturbed the argon and potassium isotope ratio of the component crystal and glass fractions of the tuffs produced by these eruptions in such a way as to cause partial and complete overprinting of the apparent ages obtained from them. The repeated occurrence of the same discrepantly low ages from different tuffs at different locations is explained as resulting from a series of distinct, short-lived overprinting events, rather than the postulation that the discrepancies result from the accumulative effect of prolonged, low energy geochemical activity in a diagenetic environment. One of the most widespread of the overprinting events recognised by Fitch and Miller occurred around 1.75 Myr (ref. 10).

We first investigated the feasibility and practical problems involved in applying fission track dating to East Rudolf tuffs and then tried to confirm or deny the presence of a widespread thermal annealing event around 1.75 Myr. The sample used was a vitric tuff from the upper part of the Kubi Algi Formation, inland from Allia Bay in the south-east of the East Rudolf basin (Kenya Grid Reference HBH 72001640). The tuff was collected by A. K. Behrensmeyer and V. J. Maglio in 1970 from section B5. A minimum age of 3.0 Myr was suggested by Maglio for the Kubi Algi formation; Fitch and Miller have proposed an age of around 3.9 Myr based on conventional K/Ar and ^{40}Argon/^{39}Argon age determinations. More precise dating was precluded by the very complex age spectrum obtained; analysis of the spectrum indicates both partial contamination by an older volcanic fraction included in the tuff and also minor discrepancies in argon loss caused by subsequent events.

Petrologically the sample used for this track study is an unconsolidated volcanic ash, largely composed of glass shards but also containing abundant calcite grains, small amounts of biotite and feldspar, and numerous minute grains of iron oxide. Only the glass shards can be regarded as definitely juvenile; microscopic examination shows the shards to be fresh, strongly vesicular and bearing no sign of devitrification.

The fission track dating method[11] and, more specifically, the use of volcanic glass in track dating[12–15] have been described previously. Uncontaminated glass shards were separated from the ash sample by hand picking beneath a binocular microscope; the shards were divided into two aliquots. One aliquot was heated to 250° C for 52 h, which was observed to anneal the spontaneous tracks present; it was then irradiated using a thermal neutron fluence of approximately 1×10^{14} neutrons cm^{-2}. The fluence was carefully monitored using NBS standard glass SRM614, with a uranium content of 0.82 p.p.m., allowance being made for the depleted ^{235}U. The natural and irradiated shards were simultaneously mounted in epoxy resin, polished and then etched in 2.75 M hydrofluoric acid for 25 min at 20° C. The two aliquots were consecutively counted using an eyepiece graticule in a Reichert Zetaplan microscope; incident illumination with a magnification of ×256 was used. The natural shards revealed tracks formed by the spontaneous fission of ^{238}U and the irradiated shards showed tracks resulting from the neutron-induced fission of ^{235}U.

Table 1 shows the resulting spontaneous and induced track densities; it presents an apparent fission track age of 1.8 Myr. No precise value for the error has been attached, since errors quoted in previous studies have been of questionable value. Considering the track counting, fluence dosimetry and the uncertainty of the value of the ^{238}U fission decay constant, a minimum value of 10% is given for the uncertainty of the date. The variation in track density between shards was about 20–30%, indicating a relatively homogeneous uranium distribution. Since fission tracks in glass are particularly susceptible to thermal annealing[16], the mean track diameters of both the induced and spontaneous tracks were measured. Comparison of these results revealed no significant difference in track diameter, indicating that the specimen has either suffered no thermal annealing or that it has been totally annealed at 1.8 Myr.

As this tuff is within the Kubi Algi Formation and is stratigraphically below the 2.6 Myr KBS Tuff, the second alternative is accepted as the correct interpretation. Thus this study has shown that fission track dating of Plio-Plistocene vitric tuffs from the Lake Rudolf area is practicable and that in appropriate circumstances this method can produce evidence of important events in the

Table 1 Spontaneous and induced track densities of vitric tuffs.

Sample and location	No. spontaneous tracks counted (1)	Spontaneous track density cm^{-2} ρ_s	No. induced tracks counted (2)	Induced track density cm^{-2} ρ_i	Fission track date (3)
AJH64 Kubi Algi SB5–R3	403	2.558×10^5	987	5.871×10^5	1.8×10^6 yr

(1) Total tracks in 100 natural shards; an area of 1,681 μm² counted in each shard.
(2) Total tracks in 100 annealed irradiated shards; an area of 1,681 μm² counted in each shard.
(3) Neutron fluence = 8.59×10^{13} neutrons cm^{-2}, induced track density in dosimeter glass 518 tracks cm^{-2}, 89 tracks counted in 10,000 fields; spontaneous fission decay constant for ^{238}U taken as 8.42×10^{-17} yr^{-1} (ref. 17).

history of the rocks, other than or in addition to the age of initial volcanism. The apparent age obtained from the sample studied indicates that it was subjected to thermal annealing around 1.8 Myr and this can be taken as additional confirmation of the geologic reality of the important overprinting event around 1.75 Myr, indicated by previous K/Ar and ^{40}Argon/^{39}Argon studies[10].

I thank my colleagues at Birkbeck College for their assistance in this work. I was supported by grants from the Natural Environment Research Council and the Science Research Council.

Oxidation effect on the analysis of iron in the interstitial water of recent anoxic sediments

RECENT studies on the changes in composition of interstitial water during its separation from sediments[1-3] prompted us to evaluate the effect of squeezing on the concentration of ferrous iron within the interstitial water. Sediment samples were taken in northern Chesapeake Bay (38°56′ N and 76°25′ W) with a Benthos gravity corer. Layers of sediment were immediately extruded from the plastic coring tube and loaded into nylon squeezer barrels. The interstitial water was squeezed from the sediment through a 0.22 μm Millipore filter by the pressure of nitrogen acting against a rubber diaphragm[4]. The water drained directly into a calibrated test tube containing a solution of *o*-phenanthroline, buffered at *p*H 3.6, and the iron content was determined colorimetrically[5].

During attempts to determine the precision of the analysis, we discovered that the dissolved Fe(II) concentration in the interstitial water increased during the squeezing process. Figure 1*a* shows the Fe(II) concentrations in consecutive aliquots of 3 ml as a function of volume of interstitial water emerging from the squeezer. The shape of the squeezing curve, a rapid initial rise in concentration to a constant value, was observed in every subsequent experiment.

We investigated five factors which could cause the increase of the interstitial Fe(II) concentration: filter brand, filter pore size, temperature and pressure of squeezing, and the presence of oxygen. In all of the experiments, excluding the one comparing oxygen-rich with oxygen-free conditions, all manipulations were carried out in a nitrogen atmosphere. During squeezing we found no significant differences in the concentration of dissolved Fe(II) in interstitial waters squeezed through Millipore, Gelman and Nucleopore filters, nor in waters squeezed through Millipore filters with pore sizes of 0.22, 0.10, 0.05 and 0.025 μm. Interstitial Fe(II) concentrations did not vary with squeezing temperatures of between 7 and 20° C nor with squeezing pressures of between 50 and 200 pound inch^{-2}. The only factor which appreciably affected the iron concentration was the presence of oxygen.

Although there have been several studies on the concentrations of trace constituents in the interstitial water of anoxic sediments[6-9], nobody to our knowledge has attempted to prevent the oxidation of these waters by any means other than rapid handling of the sediment. We have evaluated the importance of oxidation. Nine cores were taken in rapid succession; a layer of each core, 67–72 cm below the sediment–water interface, was extruded, homogenised and loaded into two 2.5 cm squeezers containing deoxygenated filters in a glove bag from which oxygen had been purged with nitrogen.[11,12] One of the pair of squeezers from each core was never exposed to

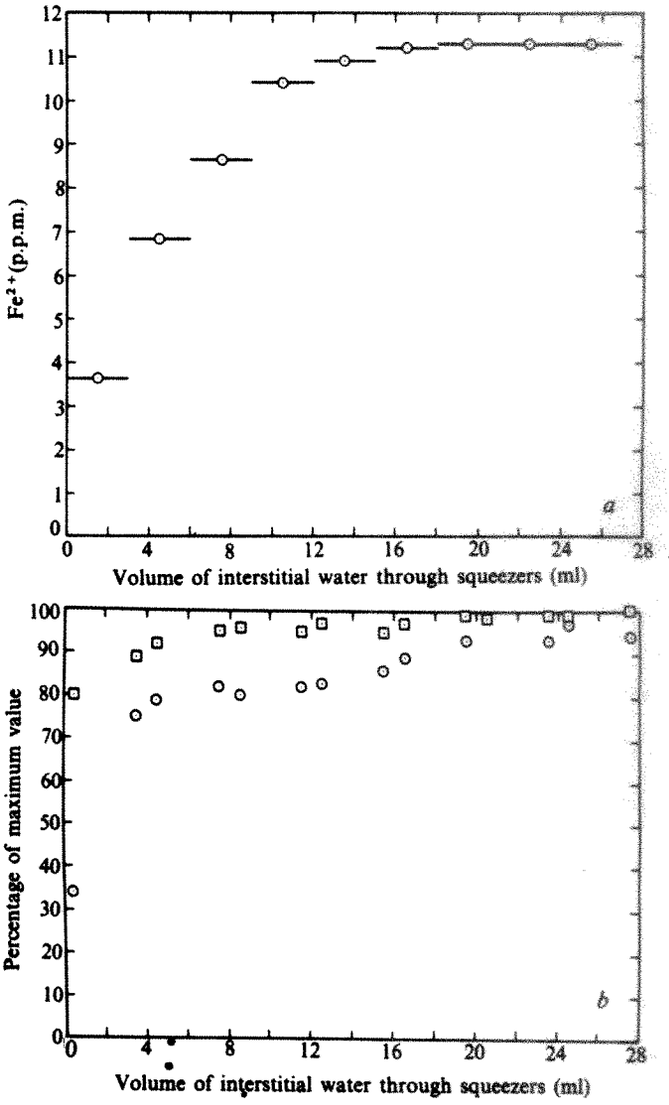

Fig. 1 *a*, Change in concentration of dissolved ferrous iron as interstitial water is squeezed. Horizontal lines indicate consecutive 3 ml aliquots analysed. *b*, Comparison of the changes in concentration during squeezing under nitrogen (□) and air (○).

the atmosphere and was manipulated under nitrogen. The second squeezer of each pair was removed from the nitrogen glove bag after loading and exposed to the atmosphere for 15 min with its top removed. Consequently, the surface of the sediment and the top of the drainage tube were exposed to oxygen for a period of time approximating rapid manipulation of a sediment core. These latter samples were then squeezed in air. Squeezing began at the same time for both the exposed and unexposed samples. An aliquot was taken simultaneously from each of the squeezers after 15 ml of interstitial water had been squeezed. In eight of the nine cores the Fe(II) concentrations in the interstitial waters squeezed under nitrogen were greater than those squeezed in air; and in five of these eight, the difference between the exposed and unexposed samples exceeded 50%. The mean of the nine samples squeezed in air was 10.0 p.p.m.; in nitrogen, 12.9 p.p.m.

We repeated this experiment using a sediment core stored at 4° C. Successive 1 ml aliquots of the interstitial water passing through duplicate squeezers were analysed for ferrous iron in order to determine the change in concentrations as a function of volume. Figure 1*b* shows the concentrations plotted as a percentage of the maximum value. The results indicate that the difference in ferrous iron concentration of the interstitial water squeezed in air and in nitrogen occurs primarily during the squeezing of the first 15–20 ml. We conclude that discrete sampling and analysis of the aliquot directly from the squeezer, under a nitrogen atmosphere, is the best method of ensuring analytical accuracy.

Inorganic oxidation of dissolved ferrous iron is rapid in the neutral *p*H range, 6.8–8.0, typical of interstitial waters from Chesapeake Bay[10]. We observed a noticeable change in colour, from black to grey, extending several millimetres into the top and bottom of sediment samples extruded and squeezed in air. This same change in colour occurred in sediment samples exposed to air and is a result of oxidation[11]. Sediment protected by a nitrogen atmosphere during the entire sampling operation remained black for the duration of the procedure.

The rapid change in Fe(II) concentration observed in the initial period of squeezing must result from the oxidation of ferrous ion to ferric hydroxide by the small amount of oxygen trapped in the squeezer during transfer of sediment from the core to the squeezer. As oxygen is consumed, the Fe(II) concentration levels off at its true value. In our samples oxidation significantly affected the concentration of Fe(II) up to values of 10–20 p.p.m. The effect on other trace metals whose concentrations fall in the parts per 10^9 range, either directly through reaction with oxygen or indirectly through interaction with amorphous ferric hydroxide[12] would be even more pronounced. Acidification of squeezed samples does not alleviate the problem because the dissolved Fe(II) is oxidised and lost from solution within the squeezer. Thus, trace metal analysis of anoxic interstitial waters rich in iron must be performed in an inert atmosphere.

We used methods of oxidation protection in an investigation of the composition of interstitial waters from a station in northern Chesapeake Bay (Fig. 2*a-f*). Phosphate was determined colorimetrically and carbonate alkalinity titrimetrically[14]. The distribution of sulphide, *E*h and *p*H were determined with electrodes. The core was sampled at intervals of 2 cm to a depth of 12 cm and then at intervals of 7.5 cm to a depth of approximately 100 cm.

Below a depth of 1 to 2 cm sediments from Chesapeake Bay are anoxic and the decomposition of organic matter enriches carbonate alkalinity and phosphate with depth in the interstitial water. The generation of sulphide from the concomitant bacterial reduction of sulphate is commonly assumed to immobilise iron as an iron sulphide. We observed, however, two layers of significant dissolved Fe(II) mobilisation into the interstitial waters throughout the sediments of the northern Chesapeake Bay: a narrow band between the surface and 10 cm, and a broad layer below 40 cm. The maximum concentrations of iron observed in the interstitial water, consistently between 500 and 1,000 μg atom l^{-1} (28–56 p.p.m.), are between one and three orders of magnitude greater than the concentrations observed in anoxic sediments by other investigators[6–9]. These

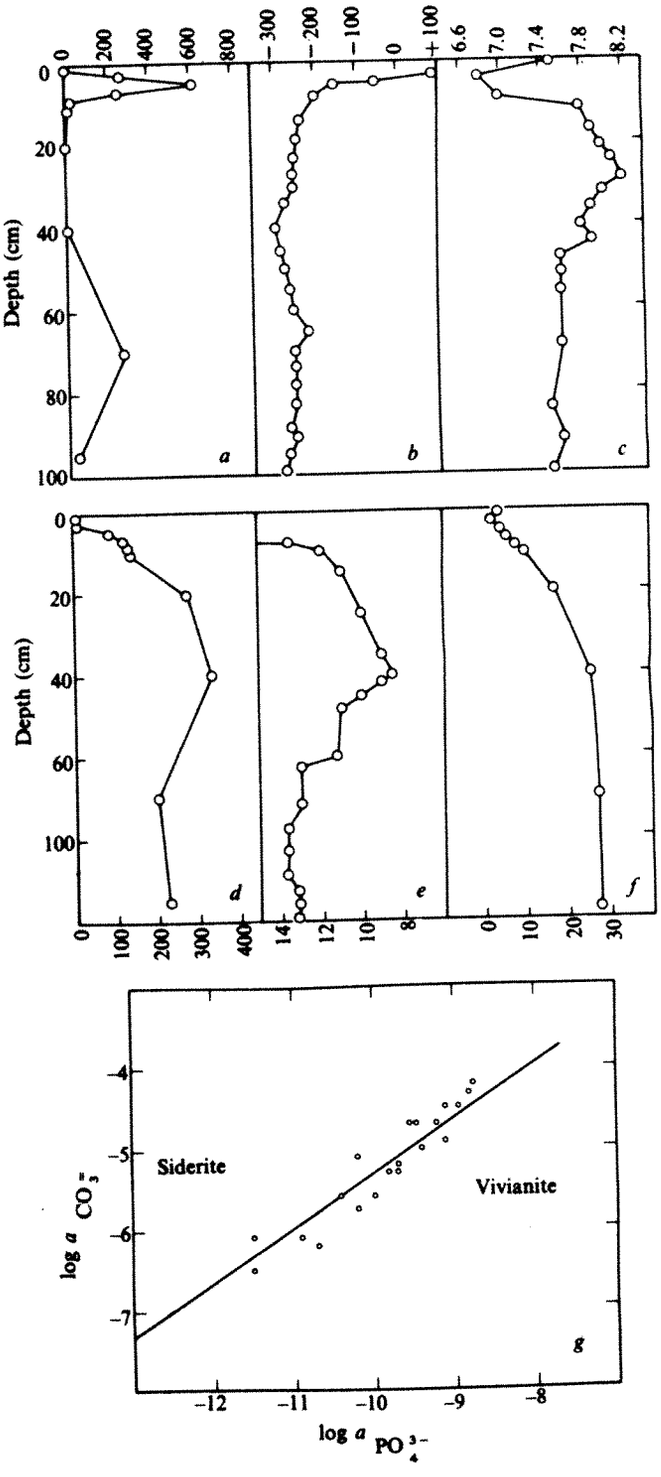

Fig. 2 Interstitial water chemistry at station 2, 38°56′08″N and 76°25′18″ W; water depth 12 m. Figures *a* to *f* are plotted as a function of depth below the sediment–water interface. *a*, Fe^{2+} (μg atom l^{-1}); *b*, *E*h (mV); *c*, *p*H; *d*, reactive phosphate (μg atom l^{-1}); *e*, PS^{2-}; *f*, carbonate alkalinity (meq l^{-1}); *g*, equilibrium among siderite, vivianite and interstitial water. The activities on the plot were calculated from the concentrations using an ion-pairing model and the Debye–Huckel equation. The speciation of all known inorganic ion pairs of importance was computed as a function of ionic strength from published stability constants; in this treatment, therefore, the activity of an ion is the product of the concentration of the free, uncomplexed ion and its individual activity coefficient.

unusually large concentrations may be due to the unique characteristics of the sediments of Chesapeake Bay or to the lack of sufficient oxidation protection in previous investigations. Between 2 and 5 cm below the sediment–water interface the strong positive iron gradient probably results from the equally strong negative *E*h gradient. Between depths of 5 and 10 cm we can pinpoint no single unambiguous cause for the rapid decrease in the ferrous iron concentration, since the concentrations of sulphide, phosphate, and carbonate, all increased rapidly.

The analytically determined concentration of a dissolved species consists of the free ion concentration plus the concentrations of that species present in ion pairs and soluble complexes[15]. The product of the free ion concentration and the appropriate activity coefficient yields the activity of the species. Our computed activities of carbonate and phosphate are plotted in Fig. 2*g*, in which the line represents the theoretical equilibrium between siderite, $FeCO_3$, and vivianite, $Fe_3(PO_4)\cdot 8H_2O$ (refs 16, 17). The close correspondence between the data points and the equilibrium line suggests that in these pore waters the activities of Fe(II), carbonate, and phosphate are co-dependent. Further, the close negative correlation between the Fe(II) and sulphide distributions suggests that sulphide may be controlled by iron in these iron-rich sediments.

In anoxic sediments, therefore, the distribution of Fe(II) in the interstitial water can be a sensitive indicator not only of general redox conditions but also of the chemical equilibria of certain nutrients. We conclude that the handling of anoxic sediments and the analysis of iron-rich pore waters must be carried out in an inert atmosphere if accurate results are to be obtained.

We thank Dr G. M. Cafon for commenting on the manuscript, and M. Manella, R. Mervine, and G. Holdren for air in the analyses. This work was supported by the United States Atomic Energy Commission.

Spirorbid — algal stromatolites

Modern stromatolites may be formed in certain environmental settings by several different processes and organisms[1], although they are predominantly produced by blue-green algae. Algal stromatolites occur in the Lower Triassic Bunter formation (Buntsandstein) in the Krosno Odrzańskie region of western Poland. Spirorbid tubes often occur in the immediate vicinity of these stromatolites (Fig. 1), which are usually found unattached. Because spirorbid tubes are generally attached to

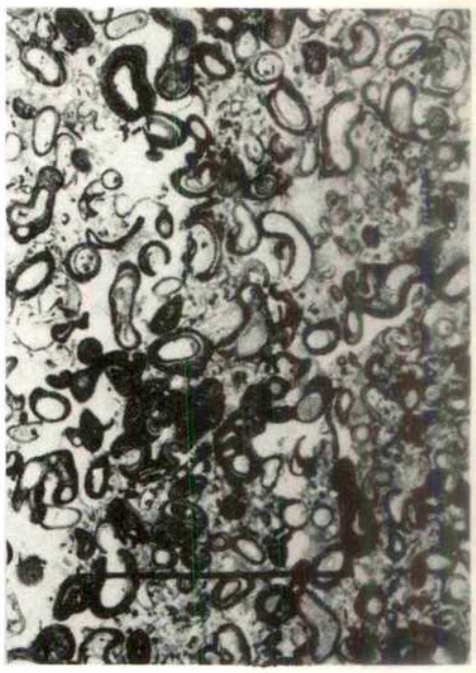

Fig. 1 Photomicrograph of organodetritic carbonate. Fossils are predominantly spirorbids. Some spirorbid tubes form oolitic nuclei. Scale bar, 1 cm.

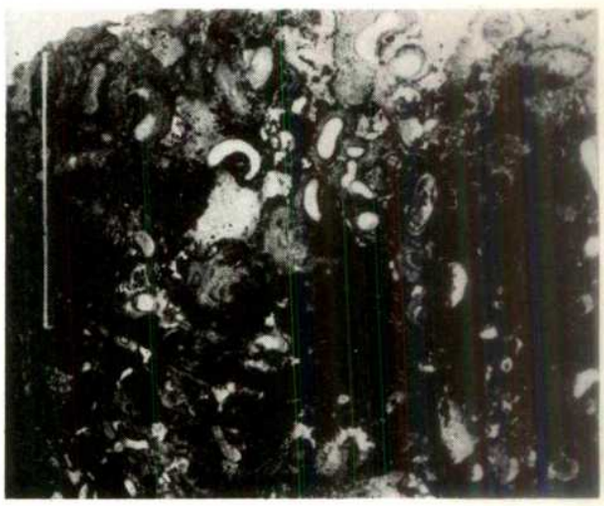
submerged objects, mainly shells and pelagic and sedentary algae[2], such unattached occurrences seem to indicate that the spirorbids lived on algae.

Associations of stromatolites and spirorbids[3] or serpulids[4] have been found before. Garwood[3] mentions that in the Lower Carboniferous Main Algal Series of Tuedian Beds in Cumberland and Roxburghshire, the surfaces of small domelike



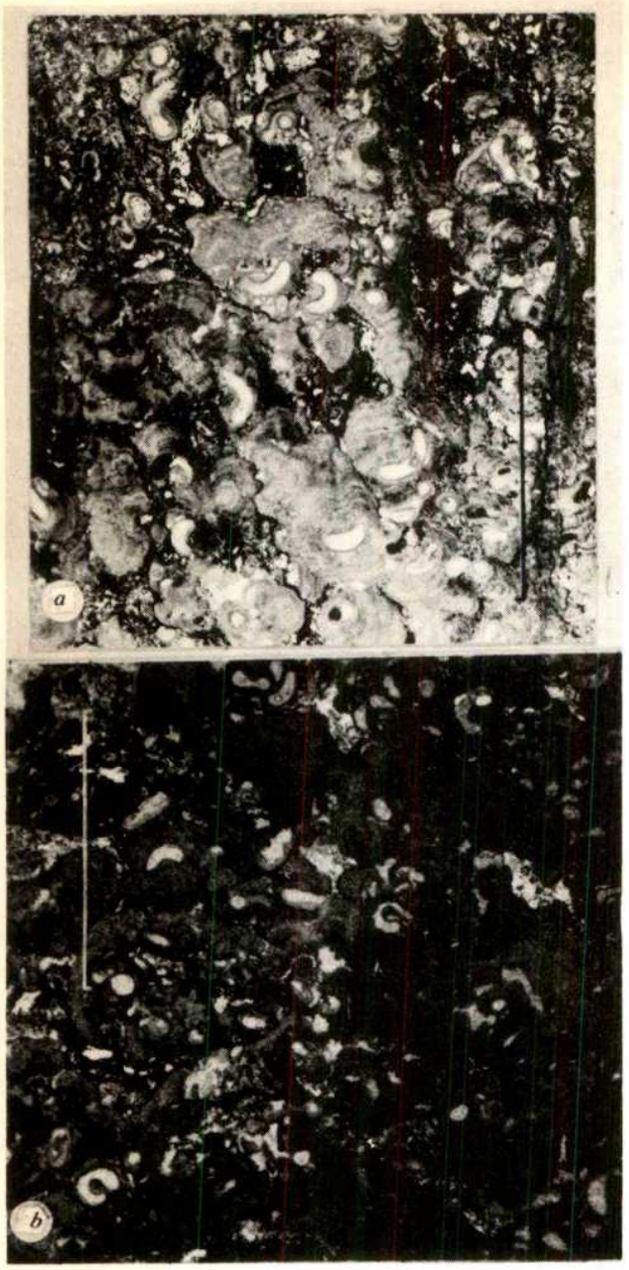


Fig. 2 Photomicrograph of spirorbid and algal-built stromatolites. Larger stromatolite fragments are found in any position. Subsequent algal laminae on the top of the debris. Scale bar, 1 cm.

Figs. 3 *a* and *b* Photomicrograph of spirorbid and algal-built stromatolites. Scale bar, 1 cm.

'protuberances' (stromatolites?) are frequently encrusted with adherent tubes of *Spirorbis*. Spirorbids also occur within the Bunter stromatolites (Figs 2 and 3). The stromatolitic structures developed on spirorbid tubes, and the detritus may contain small amounts of spirorbid fragments. As a rule, however, spirorbids occur in great number inside stromatolites (Figs 2 and 3) which are built not only by algae but also by spirorbids themselves. In contemporaneous worm–algal stromatolites from the Persian Gulf[5] burrowing worms build mounds which may be coated with algae but the worms do not enter into the framework of the stromatolitic structure.

The unique nature of spirorbid–algal association in the Krosno Odrzańskie region is best explained as resulting from the particular environmental conditions prevalent during the deposition of the Bunter stromatolite-bearing rocks. The Bunter algal stromatolites originated in upper subtidal and lower peritidal zones. Stromatolites only occur sporadically in the upper peritidal zone. Tidal influence on sedimentation is reflected in changes of stromatolitic structures. These can best be interpreted as resulting from repeated periodic events: influxes of coarse sediment, commonly evident in stromatolitic sequences, could have resulted from periodic catastrophic erosion and deposition. Crust-building communities lived in such tidal marine environments. Flakes and chips of stromatolites are common in the interareas of stromatolitic structures (Fig. 2). Larger stromatolite fragments also occur as clumps which have been rolled and are found in any position, commonly on their sides or upside down (Fig. 2). On top of the debris later colonies of algae may develop (Fig. 2). Stromatolitic intraclasts and characteristic sequences of stromatolitic structures indicate a high energy environment.

The spirorbid–algal community therefore seems to be an ecological adaptation to a rather high energy environment. The spirorbids probably reinforced the structure of spirorbid–algal stromatolites, which were therefore more resistant to the erosional effects of waves and currents than were ordinary algal stromatolites.

Infrared Zimm plots for macromolecular characterisation

The light scattering method is an accepted procedure for the measurement of the molecular weight (M) and the size of macromolecules in solution. This information is most readily available for particles the major dimension (ξ) of which is of the order of the wavelength (λ) of the light incident on the system. Provided that they are not too optically dense, such particles satisfy the conditions

$$|m-1| \ll 1 \text{ and } \frac{2\pi\xi}{\lambda}|m-1| \ll 1$$

and are described in terms of the Rayleigh–Gans–Debye[1,2] (RGD) scattering theory. In this equation, m is the ratio of the refractive index (n) of the solute to that of the solvent (n_0).

If the particles are relatively small in comparison to λ (that is $\xi < \lambda/20$) then the simple Rayleigh[1,2] theory is applicable but no information is obtained about the particle size. Alternatively, if the particles are too large the scattered intensity becomes an oscillating function of θ and complicated interference effects occur. For this case, a general solution has been developed[3], but only for spheres.

With the improvement of sources and detectors which operate in the infrared, it is possible to increase the wavelength of scattering experiments so as to bring some particles which exhibit interference peaks in the visible region into the realm of the RGD theory, at least over a restricted angular range. Measurements can then be made on readily modified commercial apparatus and the data can be analysed according to the straight forward Zimm plot[1] method. The radius of gyration (S) and M can then be directly determined, even with polydisperse samples. An alternative procedure[4], that of measuring at extremely low angles θ to the forward direction of the incident beam, requires a purpose built apparatus.

We are at present engaged in a study of the scattering from aqueous suspensions of bacteria, with dimensions typically of the order 1 – 2 μm. Preliminary studies on *Serratia marcescens* provide an example. Figure 1 shows that this system exhibits

angular scattering peaks in the visible spectrum, even at the lowest values of θ accessible to a commercial scattering instrument. The source of our scattering photometer, a SOFICA 4200, was replaced by a continuous working Nd^{3+} YAG laser which operates at $\lambda = 1{\cdot}06$ μm. The detector was replaced by a combination of an infrared converter tube (type EMI 9606) and a 13-stage photomultiplier (type EMI 9635QB). Infrared-sensitive photomultipliers are a simpler alternative to this arrangement. The light trap was modified so that measurements could be made up to $\theta = 10°$ and an oscilloscope was used to record the photomultiplier response. These are all relatively trivial changes. The Zimm plot (Fig. 2) was then obtained from data for four different dilutions of the bacterial suspension. The experimental precision was commensurate with that of visible scattering experiments.

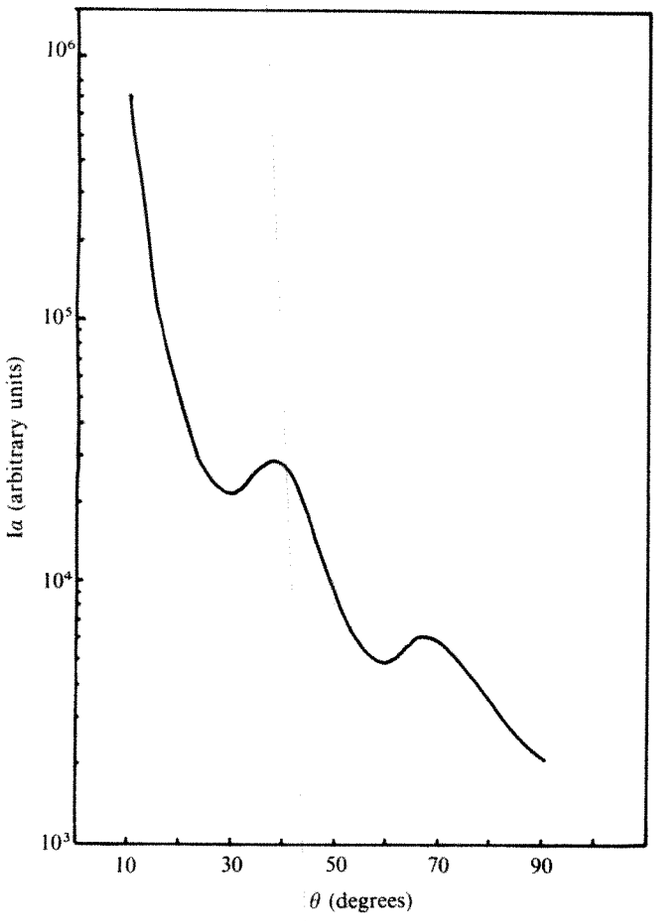

Fig. 1 Part of the angular scattering profile for *S. marcescens* in water. Data for $\lambda = 436$ nm and a suspension concentration of $2{\cdot}4 \times 10^{-6}$ g ml^{-1}. Oscillations are present even at low angles. The factor $\alpha = \sin\theta\,(1+\cos^2\theta)^{-1}$.

A value of 0·18 was assumed[5] for the refractive index increment ($^{dn}/_{dc}$), necessary for the interpretation of the plot intercept[1]. This value is strictly for the visible region of the spectrum and does not vary much with wavelength provided that no absorption band exists between visible wavelengths and 1·06 μm. This was verified experimentally. We are developing a method for the direct measurement of ($^{dn}/_{dc}$) in the infrared region. From Fig. 2, values of $M_W = 1{\cdot}0 \times 10^{11}$ and $(\overline{S^2})_z^{\frac{1}{2}} = 0{\cdot}34$ μm were determined. The latter is equivalent to a spherical diameter $\bar{d}_z$ of 0·88 μm. The subscripts refer to the relevant polydispersity averages. These values correspond to an average bacterial mass of $1{\cdot}7 \times 10^{-13}$ g. This mass and the particle size agree with other experimental data for this system[6].

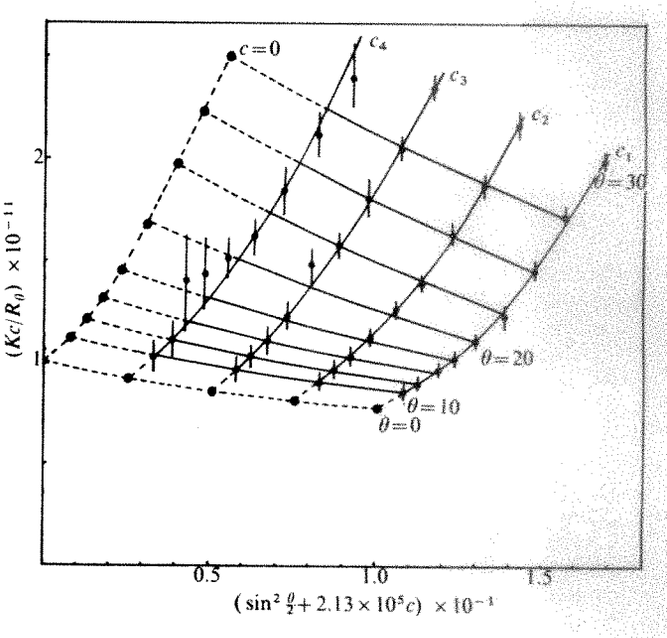

Fig. 2 Zimm plot for *S. marcescens* at $\lambda = 1{\cdot}06$ μm. C was the stock concentration of $4{\cdot}7 \times 10^{-7}$ g ml^{-1}. The dilutions were as follows; $c_1 = C$, $c_2 = 0{\cdot}75C$, $c_3 = 0{\cdot}50C$, $c_4 = 0{\cdot}25C$.

We therefore conclude that with the advance in infrared lasers and instrumentation it is possible to adapt conventional, commercial scattering photometers to work in the infrared. Provided that neither solute nor solvent are absorbing at the selected wavelength, particles which are too large to be studied through the RGD scattering methods in the visible region of the spectrum conform to the regular Zimm plot procedure when the incident wavelength is in the infrared. Their molecular weights and sizes may then be evaluated with relative ease.

Finally, the method can be extended well beyond the wavelength of the present preliminary experiment. For example, by modifying the optics, the present experiments could be extended to the 10·6 μm wavelength of the CO_2 laser. Airborne particles could then be studied. The combination of both increased wavelength and low angle measurement is doubly beneficial.

Fossils in mélanges

So-called 'tectonic' mélanges in many parts of the world seem to contain a disproportionately high number of fossils relative to the enclosing rocks. This is particularly true of mélanges in 'greywacke type' terrains, in particular the Esk Head Mélange[1] in the otherwise sparsely fossiliferous Torlesse Zone of the Alpine Assemblage[2] in the New Zealand Geosyncline, the mélange belts of the Franciscan Assemblage of California (M. C. Blake, jun., personal communication), and the Liptrap Formation of southern Victoria, Australia. In addition, the fossils contained in mélange belts commonly contain shallow water forms, and in extreme cases even terrestrial fossils (D. L. Jones, personal communication).

These facts alone seem to preclude postdepositional tectonic modification of part of a sedimentary sequence as the sole means of mélange formation. Rather, we suggest that the processes leading to the formation of at least some mélange belts resulted in the development of localised, specialised sedimentary environments during deposition, probably in shallow water and commonly accompanied by submarine volcanism. Continuation of the same tectonic regime, possibly in an accentuated or modified form, then led to the formation of mélange belts in parts of the deposited, but only partly consolidated, sedimentary sequence.

We fully support the suggestion[3] that the term mélange should be used only in a descriptive sense and that the prefixes 'sedimentary' and 'tectonic' should be used with the utmost caution.

Light scattering from soap films

If a strong light beam falls on the surface of a liquid, most of it will be reflected and refracted in certain directions, but a small part will be scattered in all other directions. This light scattering is caused by small surface ripples (corrugations) arising from thermal motion. The scattering intensity is proportional to kT/γ, where k is the Boltzmann constant, T the absolute temperature and γ the surface tension. In the case of a thin, free, liquid film (as found in soap bubbles), the scattered light also contains information about the interaction forces between the two film surfaces. According to the theory of Vrij[1], the second derivative, d^2F/dh^2, of the interaction free energy, F, between the two film surfaces, with respect to the film thickness, h, can be obtained in this way.

When electrical double layer and van der Waals forces are operative in the film one may write[1] $d^2F/dh^2 = B\kappa^3 \exp(-\kappa h) - A/(2\pi h^4)$, where B is a function of the surface potential, κ is the reciprocal Debye–Hückel thickness and A is the van der Waals–Hamaker constant.

Although a few results have been published[1,2], no measurements that would corroborate the theory in a completely satisfactory manner have ever been reported. Here we present some results for films drawn from a solution containing 8.2×10^{-4} M cetyltrimethylammoniumbromide (CTAB) and 8.4 (weight) % glycerol. Experiments were carried out on draining films (varying h) at constant angles. From plots of $\ln[d^2F/dh^2 + A/(2\pi h^4)]$ against h, the values of κ were calculated. In the (very small) van der Waals term we used $A = 6.28 \times 10^{-20}$J. From the values of κ, the electrolyte concentrations were calculated (Table 1) and compared with the concentration of the solution. The agreement between the two is good, in contrast with older experiments[1] where the calculated concentrations were up to 16 times too large.

Table 1 Results calculated from the thickness dependence of the light scattering (h between about 70 and 90 nm).

Angle of incidence (°)	Angle of observation (°)	κ (m^{-1})	Concentration of CTAB (mol l^{-1})
60	55.0	9.78×10^8	8.6×10^{-4}
60	54.0	8.70×10^8	6.8×10^{-4}
60	53.1	1.03×10^9	9.6×10^{-4}

After drainage of a film to constant thickness, we also studied the angular dependence of the light scattering. In Table 2 the observed scattering is compared with values predicted by calculation using the results of the dependence on thickness of the light scattering. It is clear that the experimental results fit the predictions very well.

We conclude that the measurements of the thickness- and angle-dependent light scattering show that the light scattering theory is internally consistent. Further, they show the validity of the exponential thickness dependence of the electrical part of d^2F/dh^2.

Table 2 Angular dependence of the light scattering

Angle of observation (°)	Predicted light scattering ratio ($\times 10^6$)	Measured light scattering ratio ($\times 10^6$)
54	6.56	6.69
53	5.86	5.37
52	4.41	4.42
51	3.68	3.78

Role of molecular aggregates in liquid drag reduction by polymers

SMALL quantities of certain polymers dissolved in a liquid can reduce considerably the frictional drag exerted by the liquid when it flows over a surface. This effect has been observed with various solvent/polymer combinations, but most investigations involve polyethyleneoxide (PEO), polyacrylamide or guar gum in water, where the concentrations required are of the order of a few parts per million.

Although the mechanism of this drag reduction is unknown, attention has generally focused on the role played by the individual polymer molecules. There might also be entanglements or aggregates of polymer molecules[1], especially in freshly prepared solutions[2], and the breakup of these under shear, like the degradation of polymer molecules themselves[3], may explain the frequently observed phenomenon of time-dependent drag reduction. But there has been little attempt to investigate these clusters, and most workers have been at pains to eliminate their effects. Recently, however, Hand and Williams[4] have shown that in drag-reducing solutions there is an 'adsorbed-entangled' layer of polymer molecules at the liquid/solid interface and have suggested that this is responsible for much, if not all, of the drag-reducing behaviour. We report here studies[5] of the time dependence of drag reduction in solutions of PEO and polyacrylamide which provide new evidence for the existence of such aggregates and indicate that they can be much more powerful drag reducers than the individual polymer molecules.

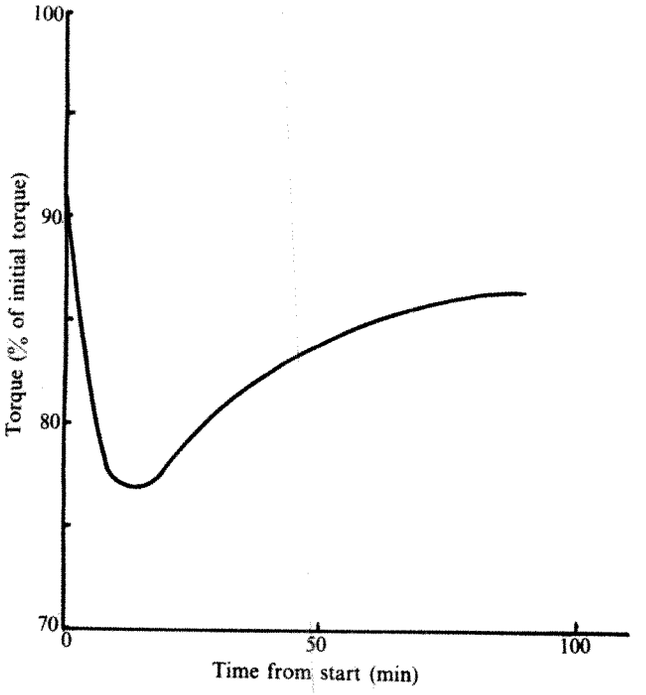

Fig. 1 Typical torque-time curve obtained with 'as received' (unsieved) material. Polyox Coagulant, 0.86 p.p.m., 840 r.p.m., 17° C.

The apparatus consisted of a vertical tapered stainless steel disk of diameter 0.23 m revolving, usually at 840 r.p.m. in a tank of water of volume 0.58 m^3. A dynamometer attached to the shaft of the disk enabled torque, and therefore drag reduction, to be measured as a function of time. The desired quantity of PEO powder was added below the water surface as a suspension in isopropanol. Most experiments were carried out using Polyox Coagulant with a molecular weight greather than 5×10^6.

The result of a typical experiment is shown in Fig. 1. The addition of the solid results in a rapid reduction of the required

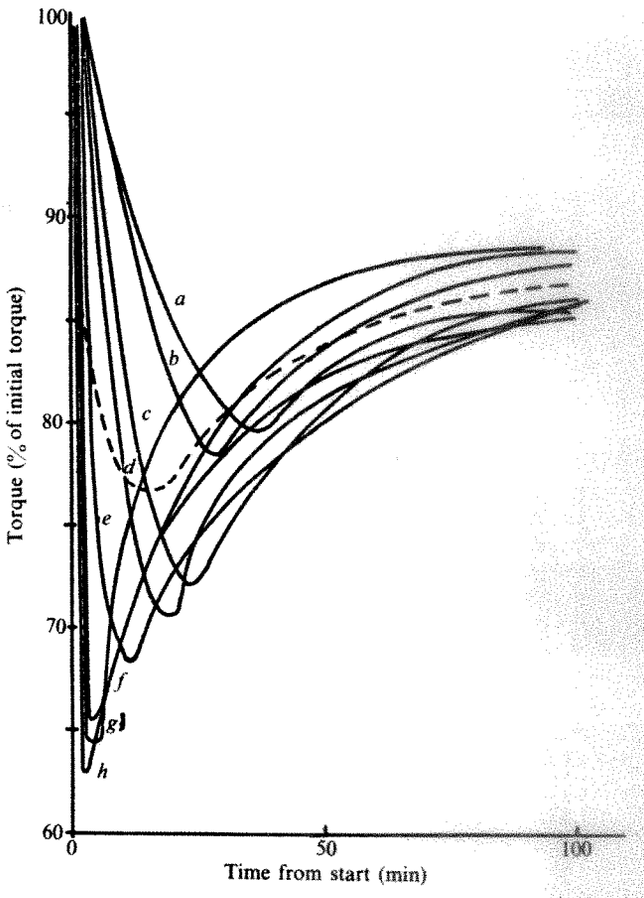

Fig. 2 Torque-time curves obtained with sieved material. The first figures refer to the BS sieve sizes, those in brackets to the mean aperture in millimetres. *a*, below 22 (over 0.71); *b*, 22–25 (0.655); *c*, 25–30 (0.55); *d*, 30–36 (0.46); *e*, 44–85 (0.26); *f*, 85–150 (0.141); *g*, 150–300 (0.079); *h*, over 300 (below 0.053). Polyox Coagulant, 0.86 p.p.m., 840 r.p.m., 17° C.

torque which, after passing through a minimum, gradually approaches an asymptotic value. This is significant because the torque might have been expected to decrease monotonously as the polymer dissolved. Experiments with sieved powder samples (Fig. 2) show that for a given final concentration, the finer the powder used the lower the minimum torque and the shorter the time taken to reach it; the 'steady-state' torque is,

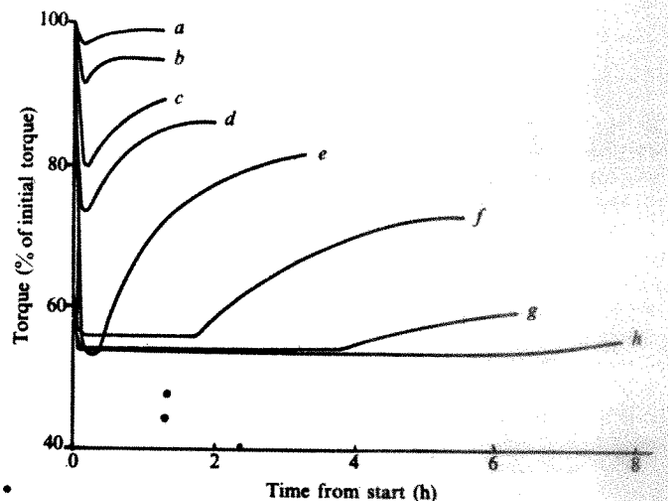

Fig. 3 Effect of polymer concentration (p.p.m.). *a*, 0.086; *b*, 0.171; *c*, 0.43; *d*, 0.86; *e*, 1.71; *f*, 4.30; *g*, 8.60; *h*, 17.1. Polyox Coagulant, 36–44 mesh (0.39 mm), 840 r.p.m., 17° C.

however, unaffected. The effect of polymer concentration using a powder of uniform particle size is shown in Fig. 3. In the particular conditions used the maximum attainable torque reduction was about 50%. This probably corresponds to complete flow laminarisation or some other hydrodynamic limitation, such as Virk's maximum drag reduction asymptote[6].

On the basis of these observations it is possible to advance the following hypothesis. When PEO powder is added to water, the particles rapidly swell to form a relatively small number of gel-like entities which circulate with the liquid and possibly attach themselves to the disk surface. By the action of shear forces at or near this surface they are broken down into a much larger number of aggregates of entangled molecules. At any one time there will be a particular distribution of aggregate sizes, which will tend to a steady state at long times.

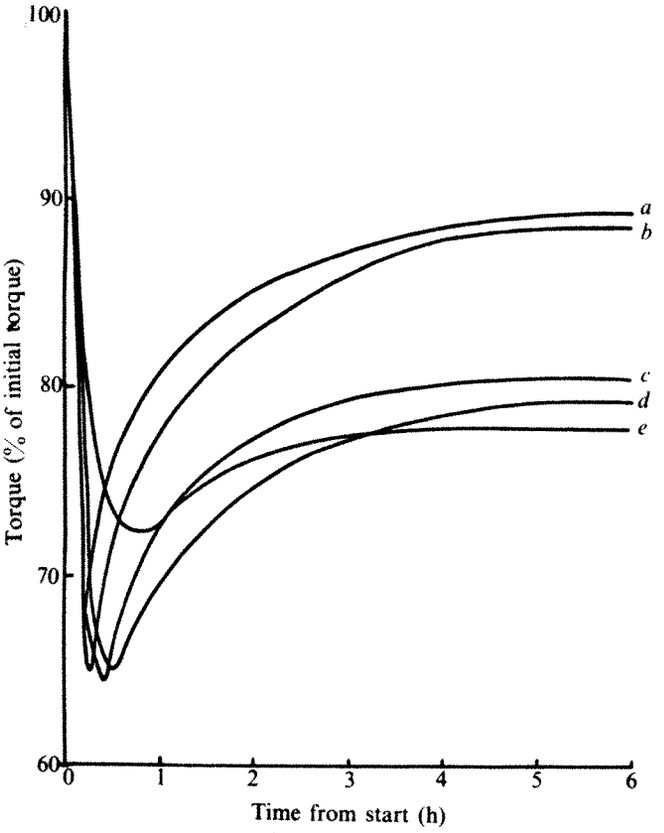

Fig. 4 Effect of disk speed (r.p.m.). *a*, 840; *b*, 720; *c*, 600; *d*, 420; *e*, 360. Polyox Coagulant, 30–36 mesh (0.46 mm), 0.86 p.p.m., 17° C.

Thus, the mean aggregate size will decrease monotonously with time while the number of aggregates or free molecules will increase. As the ability of polymer molecule aggregates to interact with eddies and thus bring about drag reduction is presumably a function of aggregate numbers and/or relaxation time, for a given set of hydrodynamic conditions the drag reduction could pass through a maximum as the optimum size distribution was reached and passed.

Strong evidence in favour of the aggregate hypothesis is provided by the effect of rotation rate on drag reduction (Fig. 4). It was found that the long-time value of the drag reduction decreased as the rotation rate increased. This observation runs contrary to the most firmly established fact in the field, that drag reduction in a stable system increases with shear rate, and suggests that the equilibrium (long-time) size distribution depends on the shear history of the solution. To test this idea, the apparatus described was used to shear a solution of PEO for 6 h at 420 r.p.m., after which the torque/speed characteristic of the disk was measured. This characteristic (Fig. 5) was quite different from that in an identical solution which had been sheared for the same length of time at 720 r.p.m. The solution subjected to the higher shear exhibited less drag reduction, presumably because of the reduced size of the active molecular aggregates.

Although these results could also be explained on the basis of molecular degradation, the effect of molecular weight (Fig. 6) supports the view that cluster formation and breakdown, rather than degradation, is the dominant effect. Thus, for a given polymer concentration, decreasing the molecular weight of the PEO from 4×10^6 to 6×10^5 more than halved both the maximum and steady-state drag reduction, while PEO of molecular weight 1×10^5 gave no drag reduction at all. Although the variation in chain length is only 40:1, the use of the 'entanglement coupling factor'[8] shows that the likelihood of chain entanglement in the highest molecular weight material is 7,000 times as great as in the lowest.

If the effects observed were a result of degradation, starting materials of different molecular weights would be expected to degrade, after a long time, to the same average molecular weight, that is, the asymptotic value of the drag reduction would be about the same in each case; in fact,

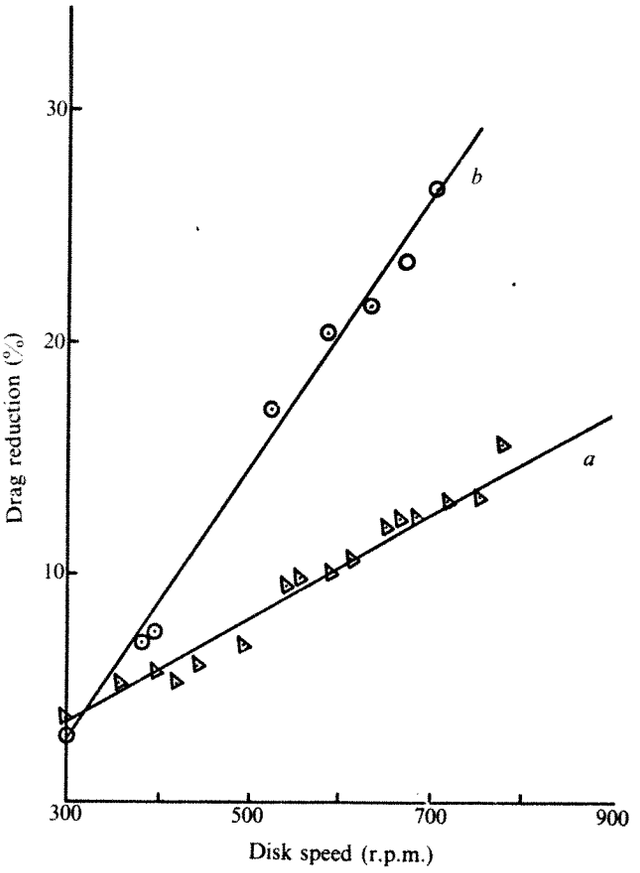

Fig. 5 Drag reduction as a function of speed for solutions sheared at 720 (*a*) and 420 (*b*) r.p.m. Polyox Coagulant, 0.86 p.p.m., 17° C.

Polyacrylamide of molecular weight about 5×10^6 exhibited similar drag-reduction characteristics to PEO, but the concentration required was somewhat greater. Guar and locust bean gums behaved differently, the drag reduction increasing with time up to an asymptotic value. The results obtained with PEO and polyacrylamide are consistent with the known tendency of many polymers to form molecular aggregates[8].

From the standpoint of drag reduction theory, the aggregate hypothesis provides an explanation of many of the anomalies reported in the literature for the PEO–water system. On the

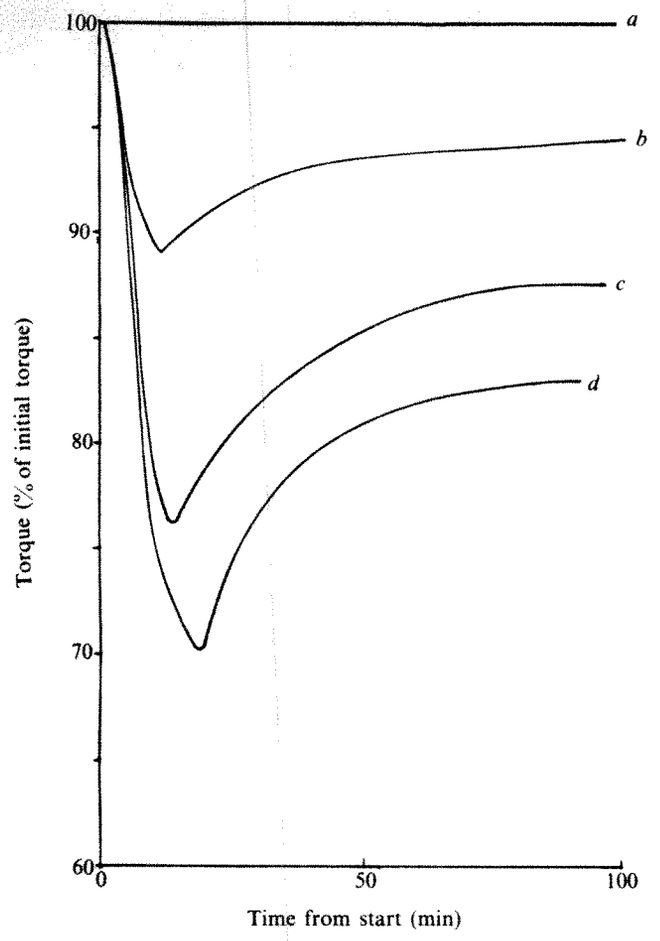

Fig. 6 Effect of molecular weight. Polyox, various grades, 30–36 mesh (0.46 mm), 0.86 p.p.m., 17° C. *a*, WSR N-10 (molecular weight 100,000); *b*, WSR 205 (molecular weight 600,000); *c*, WSR 301 (molecular weight 4,000,000); *d*, Coagulant 1 (molecular weight >5,000,000).

practical side, it suggests possible economies in the use of polymers, particularly PEO, in recirculating and non-recirculating systems; in the former the object should be to stabilise aggregates, in the latter to obtain the correct size aggregates at the right time.

We wish to thank Professor J. F. Conn and Mr A. Ferguson of the Glasgow University Ship Experiment Tank and the Science Research Council for a grant to one of us (E.H.D.). Polyox Coagulant was donated by Union Carbide Ltd.

$NaAlO_2$ and $NaFeO_2$ Polymorphism

THE polymorphism of $NaAlO_2$ and $NaFeO_2$ is well known. Both oxides form β and γ polymorphs, and although their crystal structures are known, the relationship between the β and γ polymorphs has not been described. This relationship is described here and from it a simple topotactic mechanism for the $\beta \rightleftharpoons \gamma$ transformation is deduced. Movement of only half of the cations is necessary to complete the transformation in either direction and this movement is restricted to a single, filled–empty tetrahedron jump, for each cation. The polymorphisms may be summarised:

$NaFeO_2$: $\alpha \underset{760^\circ C}{\rightleftharpoons} \beta \underset{1010^\circ C}{\rightleftharpoons} \gamma$ (refs 1–3)

$NaAlO_2$: $\beta \underset{470^\circ C}{\rightleftharpoons} \gamma$ (ref. 4)

An α form may also be prepared at high pressure[5]. Both the β and γ polymorphs have 'tetrahedral structures', that is, the cations and oxygens are all tetrahedrally coordinated. (The α form has an ordered rock-salt structure.)

β-$NaFeO_2$ and β-$NaAlO_2$ are isostructural. They have the basic wurtzite structure but with ordering of cations on the tetrahedral sites[1,2]. This cation ordering causes a lowering of the symmetry from hexagonal $P6_3mc$ in wurtzite to orthorhombic $Pbn2_1$ in β-$NaFeO_2$. A schematic (001) projection of the structure (not drawn to scale) is shown in Fig. 1. The unit cell contains two layers of close-packed oxygen atoms at heights 0 and 1/2, and two layers of cations at heights 1/6 and 2/3 (ideally and ignoring differences in cation sizes). The cations for example those at 1/6 are coordinated to three oxygens at 0 and one oxygen at 1/2. Thus, the MO_4 tetrahedra all point upwards, along *z*; linkage of adjacent MO_4 tetrahedra is by corner sharing only (Fig. 2*a*).

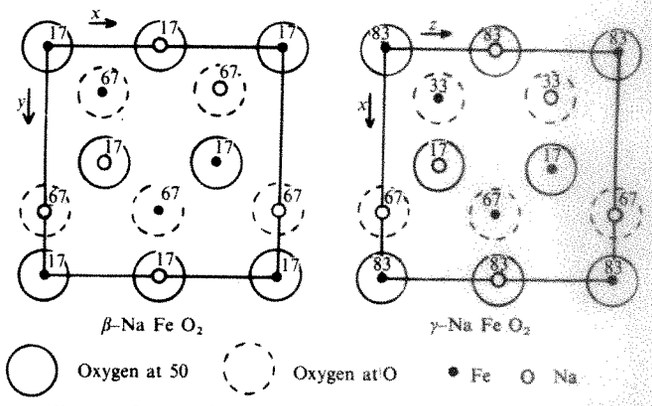

Fig. 1 Schematic projection of β-$NaFeO_2$ and γ-$NaFeO_2$ structures. The diagrams are not drawn to scale. Atomic heights, in units of *c*/100 and *b*/100 respectively, are idealised.

The structures of γ-$NaAlO_2$ and γ-$NaFeO_2$ have not been determined directly, but they are isostructural with γ-$LiAlO_2$, tetragonal $P4_12_12$ (ref. 8). The structure of γ-$LiAlO_2$ was determined independently by X-ray and neutron diffraction on single crystal and powdered specimens, respectively[7,8]. The structure has been described as a three-dimensional network of linked tetrahedra[7], its relation to cristobalite, SiO_2, has been noted[8], and it has been described as a stuffed, distorted cristobalite structure[8].

I made a model of γ-$LiAlO_2$ using cardboard tetrahedra and an alternative way of describing its structure became apparent (Figs 1 and 2*b*). Rather buckled layers of oxygen atoms occur, ideally at 0 and 1/2, which again approximate to hexagonal close packing. The cations are distributed over both sets of available tetrahedral sites; that is, at 1/6, 2/3 and

1/3, 5/6, but only half of the sites in each set are occupied (the set of tetrahedral sites at 1/3, 5/6 in β-$NaFeO_2$ are empty). The cations at for example 1/3 are coordinated to three oxygens at 1/2 and one oxygen at 0 and so these MO_4 tetrahedra point downwards. The manner of linkage of the tetrahedra is different from that in β-$NaFeO_2$ in that the tetrahedra occur in pairs. Each NaO_4 tetrahedron shares one edge with an adjacent FeO_4 tetrahedron, and *vice versa*. The remaining linkages are by corner sharing.

The β and γ structures may be classified using the nomenclature of Ho and Douglas[6]: . . . P_A T_+ P_B T_+ P_A . . . for β-$NaFeO_2$; . . . P_A $T_{+\frac{1}{2}}$ $T_{-\frac{1}{2}}$ P_B $T_{+\frac{1}{2}}$ $T_{-\frac{1}{2}}$ P_A . . . for γ-$NaFeO_2$. P_A P_B P_A . . . refers to anion layers in hexagonal close packing; T_+, T_-, indicate layers of tetrahedral sites which point up and down respectively, and $T_{\frac{1}{2}}$ indicates that only half of the sites in that layer are occupied.

The structural relationship between β-$NaFeO_2$ and γ-$NaFeO_2$ is shown in Fig. 1. The oxygen arrangement is the same in both cases and half of the cations, both Na and Fe, occupy similar positions in the two structures. The remaining Na and Fe cations, however, occupy different tetrahedral sites in the β and γ structures.

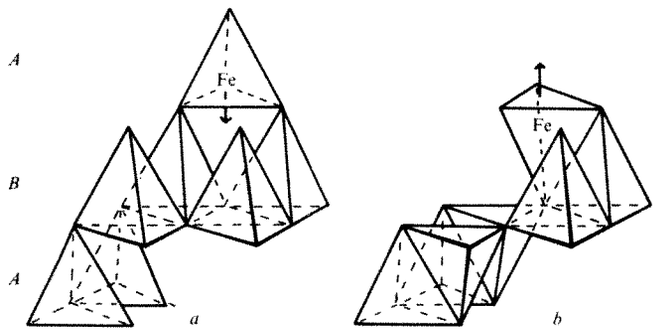

Fig. 2 Schematic structural relationship between β-$NaFeO_2$(*a*) and γ-$NaFeO_2$(*b*). *A*, *B* refer to a hexagonal close-packing sequence.

Closer examination of the structural differences between β and γ forms shows that the β⇌γ transformation may be effected by a simple topotactic mechanism. Cations at 1/3 in γ-$NaFeO_2$ can move to 2/3 (as in β-$NaFeO_2$) simply by jumping through their tetrahedron bases, that is, by passing between the three oxygens at height 1/2 to which they are coordinated. For each cation, the bond to the oxygen at 0 must therefore break and a new bond to the oxygen at 1 will form. Similarly, cations at 5/6 can transform to 1/6 and *vice versa*, by moving through the triangular window of oxygens at height 0. The relationship between the structures, and the mechanism of transformation, are shown in Fig. 2. The β-structure is shown schematically (Fig. 2*a*), with all of the tetrahedra pointing upwards, as is the corresponding γ structure (Fig. 2*b*), with half of the tetrahedra pointing upwards and half pointing downwards. The γ→ β transformation, written as . . . P_A $T_{+\frac{1}{2}}$ $T_{-\frac{1}{2}}$ P_B $T_{+\frac{1}{2}}$ $T_{-\frac{1}{2}}$ P_A . . . → . . . P_A T_+ P_B T_+ P_A . . . can be effected simply by inverting those tetrahedra which point downwards (Fig. 2*b*), and *vice versa* for the β→γ transformation.

Studies on related oxides have revealed several other sets of β, γ type systems. For example, Li_2BeSiO_4 and Li_3PO_4 have low temperature β polymorphs and high temperature γ polymorphs which are related to, but not isostructural with, β- and γ-$NaFeO_2$. Again a close structural relationship exists between the β and γ polymorphs of each pair and a simple topotactic mechanism can be postulated for the β⇌γ transformation. These results will be described soon.

Cr^{2+}-cobaloxime electron transfer reactions

Cobalt complexes of dimethylglyoxime (CH_3C:NOH.C:NOH.CH_3), commonly known as cobaloximes, form alkyl derivatives with unusually stable cobalt–carbon bonds[1,2]. These are regarded by some workers as 'model' compounds for vitamin B_{12}, a biological alkylating agent, the action of which depends on the reversible formation of a similar Co–C bond[3-5]. Various mechanisms have been postulated for this reaction[6]. The mechanisms of transalkylation reactions undergone by cobaloximes are thus of great interest; such reactions have been investigated with Hg^{2+} (refs 7 and 8) and with Cr^{2+} (ref. 9). For comparison we are studying the reaction kinetics of other cobaloximes with Cr^{2+}. These are apparently electron-transfer reactions[10-12], and should also be considered in the context of the large volume of work that has been done in that field.

Using DH^- to represent the mono-anion of dimethylglyoxime, the simple cobaloximes are of the form $[Co(DH)_2B_2]^+$, in the case where B is a neutral ligand such as NH_3 or H_2O. Neutral and anionic complexes are well known, with one and two anionic ligands respectively, and the alkyl complexes are usually neutral species of the type $[RCo(DH)_2B]$. In all cobaloximes the two dimethylglyoximato ions occupy a plane, and are linked by strong hydrogen bonds to form a pseudo-macrocyclic ligand with an N_4 donor set.

We have established that in cases in which both axial ligands are NH_3 molecules, the cobaloxime is reversibly reduced by Cr^{2+}:

$$[Co(DH)_2(NH_3)_2]^+ + Cr^{2+} \rightarrow [Co(DH)_2(NH_3)_2] + Cr^{3+}$$

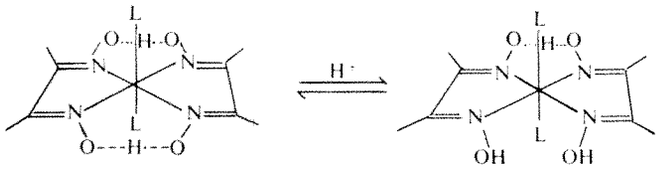
$$\swarrow H^+ \qquad O_2 \downarrow$$

$$Co^{2+} + 2DH_2 + 2NH_4^+ \not\rightarrow [Co(DH)_2(NH_3)_2]^+$$
$$O_2$$

Cobaloxime(II), the reduced form, was indentified by its visible absorption spectrum, and the kinetics of the redox reactions were monitored at 464 nm, where the product absorbs strongly. Cobaloxime(III), regenerated by oxidation of the solution (in air), was isolated as the insoluble perchlorate salt, and microanalysis showed that no chromium was incorporated. In strongly acid solutions ($pH < 1$), aquation of the reduced species is rapid; this process is acid catalysed and has an equilibrium strongly dependent on $[H^+]$.

The initial redox reaction obeys the rate law

$$\frac{d[Co^{II}]}{dt} = k_{obs}[Cr^{2+}]\,[Co^{III}],$$



where $k_{obs} = 40 + 780\,[H^+]$ (at 25° C)

The precise mechanism of this reaction is not fully understood. Although there is no evidence for ligand transfer, nor for a binuclear complex intermediate, an inner-sphere pathway involving the binding of chromium to one or two oxime oxygen atoms cannot be entirely discounted.

The rate depends on $[H^+]$ because cobaloximes act as weak bases, thus

$$[Co(DH)_2B_2]^+ + H_3O \underset{}{\overset{K_B}{\rightleftharpoons}} [Co(DH)(DH_2)B_2]^{2+} + H_2O$$

The K_B values for many neutral alkylcobaloximes have been determined[1,7], and for these species are generally of the order of 3-4. For the cationic simple cobaloximes a lower value is expected because of the charge effect; our attempts to determine K_B values for the bisammino complex have so far been unsuccessful, but *p*H measurements in acid solution indicate an upper limit of about 0.5, and the linear dependence of the reaction rate on $[H^+]$, determined to $[H^+] = 0.7$ M, implies an upper limit of about 0.2. There is now considerable evidence [13, 14] that this protonation of cobaloximes leads to a significant change in structure:

Weakening of one of the strong hydrogen bonds of the pseudomacrocyclic equatorial ligands allows greater freedom of movement for at least two of the oxime nitrogen atoms relative to the cobalt ion. Thus the Frank–Condon energy barrier to the electron-transfer reaction, which results from the need for changes in coordination geometry on reduction of the metal ion, is greatly lowered. Endicott[15] has suggested that in a similar case, in which the ligand is a true macrocycle, this is the major barrier to redox processes. The reduction of electron density around the cobalt ion when the ligand is protonated should also increase the rate of electron transfer to that ion. The combination of these two effects clearly far outweighs the decrease in stability of the 'precursor' ion pair, or complex, formed by the two cationic reagents, when the charge on the cobalt complex is increased.

When alkylcobaloximes react with Cr^{2+}, the rate also depends on the acid. Both terms in the expression for the rate constant are lower than those that we have observed and the protonated and non-protonated species react at virtually the same rate.

If the cobaloxime is considered as a complex of Co^{III}, then the observed reaction

$$[RCo(DH)_2H_2O] + Cr^{2+} \rightarrow [RCr(H_2O)_5]^{2+} + Co^{II}$$

is an electron-transfer process. As an inner-sphere reaction it would be unique in that the bridging ligand (for example CH_3^-) has no lone pair available to coordinate to the reductant ion while bound to the oxidant. A process can, however, be considered, intermediate between inner and outer sphere, in which alkyl transfer accompanies electron transfer although no bridged precursor complex is formed. Alternatively the alkylcobaloxime can be regarded as a complex of Co^{II}, in which case the most plausible reaction mechanism is a bimolecular homolytic substitution at the carbon atom, an S_{H2} process. Both of these mechanisms are considered to be possible [9].

The absence of a rate increase on protonation of the alkylcobaloxime is however, inconsistent with the postulate of an electron-transfer process in this case, but it indicates a process in which the electron density at the Co ion is not greatly changed. (In this context is should be noted that only the non-protonated alkylcobaloximes react with Hg^{2+} (ref. 7). Consideration of the charge effect indicates that this is consistent with the formulation of that reaction as a net oxidative process on cobalt, although it may be expected that the diminution of the Frank–Condon barrier would be the dominant effect in such a reaction. It is generally agreed[7,8] that this is an electrophilic substitution reaction at carbon, an S_{E2} process.)

Further insight may be obtained from a consideration of the redox potentials of the reagents involved. These have been determined for both simple[16] and alkylcobaloximes[17,18]. Schrauzer and Windgassen[17] report one-electron reduction potentials for $[MeCo(DH)_2H_2O]$ of -1.7 and -2.42 V in acetonitrile against $Ag/AgNO_3$ (0.1 M), compared with -0.67 -1.44 and -2.42 for $[Co(DH)_2(Py)_2]^+$ under the same conditions. They conclude that the alkyl species are complexes of Co^{II}, and report[14] that the product of the first reduction is a Co^I species[19]. Honokabe and Yamazaki[18] seem to attribute the first cathodic wave to a Co^{III}–Co^I reduction, although they discuss it subsequently in terms of a one-electron process. Their results do however agree on the value of the first half-wave potential, when corrected for different reference electrodes. According to Maki[16], the first half-wave potential of the bisamminocobaloxime is only 0.43 V more negative than that of the bispyridine complex. The methylaquo species thus has a reduction potential 0.6 V more negative than the bisammine complex. In the latter case, the reduction is reversible[16], and can therefore be corrected for the reference electrode to give a value for the standard electrode potential[20] of -0.37 V. Because E^0 for the Cr^{2+}/Cr^{3+} couple is -0.41 V[21], the reduction by Cr^{2+} of any species with a reduction potential much more negative than that of the bisamminocobaloxime is, thermodynamically, an unfavourable process. The electron-transfer process by which that complex reacts with the chromous ion is therefore unavailable to the alkyl complexes.

We therefore conclude that it would be incorrect to regard the reaction of Cr^{2+} with alkylcobaloximes as a chromium–cobalt electron transfer reaction. The simplest mechanism consistent with all of the described observations is homolytic substitution at the carbon atom.

We thank the Royal Society for a grant towards the cost of equipment, and the Science Research Council for support (for M.G.S.).

BIOLOGICAL SCIENCES

Exciton-like splitting in acridine dye–nucleic acid complexes

COMPLEXES between cationic acridine dyes and nucleic acids are of considerable interest because of the wide variety of biological effects in which the interaction between the dye and nucleic acids have been implicated[1–3].

Lerman's evidence based on the X-ray study and hydrodynamic measurements of proflavine-DNA complexes remains the most persuasive for the intercalation model, that is the mass per unit contour length of DNA diminishes when complexed with the dye[4–6]. Most recent information about the nature of complexes in solution derives from studies of equilibria between free and bound dye in the form of binding curves[1] (Scatchard plots).

In spite of several studies of complexes between the chromosomal stain quinacrine (QAC)[7–13], and nucleic acids, the molecular nature of the complex is not understood[14–17]. We have now used ultraviolet absorption spectroscopy to look for exciton-like interaction in complexes between QAC and DNA, poly(dAT), and poly(dG)·poly(dC). We also measured rate constants for quenching of the fluorescence of the complexed dye by iodide ion.

The interaction of excited states of weakly coupled composite systems such as molecular crystals, dimers, aggregates and polynucleotides can be treated by the molecular exciton model[18]. The interaction between dyes and nucleic acids when the binding is strong (at high phosphate:dye (P:D) ratios) can be treated similarly[19]. In the simple theory, when only the transition dipole-dipole potential term is considered, significant interaction occurs if (*a*) there is a small energy difference between interacting states, and (*b*) the interacting transition dipoles have large transition moments.

On the basis of the intensity and energy of the transition, the S_3 absorption band of QAC (*p*H 7) (35,710 cm^{-1} (280 nm) $f = 1.15$) is the only band which could possibly show significant exciton-like interaction (in addition to dispersion and other solvent shifts) with the polynucleotide transition at 38,460 cm^{-1} (260 nm, $f = 0.10$). The other two bands, S_2 at 22,470 cm^{-1} (445 nm, $f = 0.18$) and S_2 at 29,070 cm^{-1} (344 nm, $f = 0.08$) ought to show dispersion and possibly other shifts in the complexes but not exciton-like interaction.

To ensure complete, strong primary binding[1], we worked with P:D ratios of at least 6:1 and usually 20:1. Consequently the strong 260 nm absorption in the spectrum of the polynucleotide which was unperturbed by bound dye, masked small changes in the QAC S_3 transition. Therefore, we recorded the difference spectra of dye–polynucleotide solutions (sample beam) against identical polynucleotide samples (reference beam) on our Cary 14 spectrophotometer.

Figure 1 shows spectra of free QAC and difference spectra of QAC bound to DNA, poly(dAT) and poly(dG)·poly(dC). In the spectrum of QAC bound to DNA the 445 nm and 344 nm bands of free QAC appeared at 455 nm (21,980 cm^{-1}) and 350 nm (28,570 cm^{-1}) respectively. These transitions showed dispersion shifts only. In the 260–300 nm region, however, two overlapping bands were observed at 290 nm (34,480 cm^{-1}) and 270 nm (37,040 cm^{-1}). If these two bands are decomposed into their components, we obtain two bands with maxima at 34,480 cm^{-1} and 37,540 cm^{-1}. The energy difference between these peaks (Δ) is 3060 cm^{-1}. Thus Δ is larger than the energy difference between the unperturbed interacting states, ΔE_{31} (38,460–35,710 = 2,750 cm^{-1}) by 310 cm^{-1}.

Relative to an area of 1.15 for the oscillator strength of the $S_0 \rightarrow S_3$ transition of the free dye, we observed areas of 0.40 and 0.30 for the 290 nm and 270 nm components, respectively, for the spectrum of the complex. A similar band pattern is observed with the QAC/poly(dAT) complex (Fig. 1*b*). Decomposing the two overlapping bands as before we obtained two bands at 37,315 cm^{-1} and 34,015 cm^{-1}, giving $\Delta = 3{,}300$ cm^{-1}, again larger (by 550 cm^{-1}) than $\Delta E_{31} = 2{,}750$ cm^{-1}.

In contrast to the results with DNA and poly(dAT), the difference spectrum of QAC bound to poly(dG)·poly(dC) (Fig. 1*c*) contained only a single broad band in the region of the 280 nm absorption of the spectrum of free QAC.

No noticeable change in the difference spectra was observed when the P:D ratio was varied from 50:1 to 5:1. However, when the P:D ratio was reduced from 5:1 to 1:1, the doublet became a broadened maximum at 280 nm. Since the low P:D region corresponds to that in which weak binding occurs[20], the absorption at 280 nm can be attributed to weakly bound or free dye.

The dramatic difference in the 280 nm region of the spectra of free QAC bound to DNA and poly(dAT) is good evidence that the interaction between the S_3 state of QAC and its environment is not due to a simple dispersion shift.

Since the interaction energy (310 cm^{-1}) is smaller than the initial level separation (2,750 cm^{-1}) by almost an order of magnitude, the exciton model is not strictly applicable either. However, the transition moments are associated with broad bands rather than sharp lines and these bands overlap considerably (see Fig. 1). Therefore, resonance type interactions do occur as in Förster energy transfer and this may account for the exciton-like behaviour, that is the large intensity redistribution and pronounced band shifts and splitting. It therefore seems reasonable to attribute the two

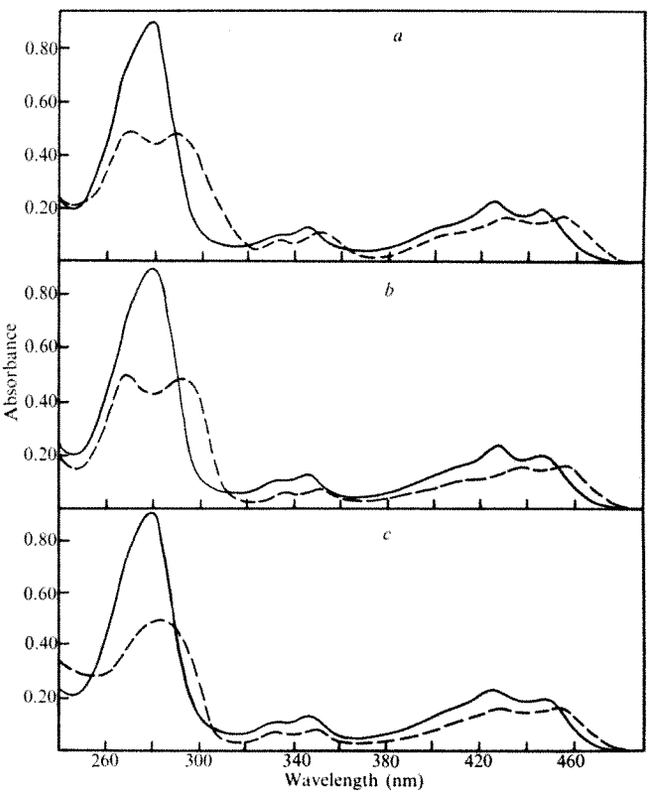

FIG. 1 Quinacrine-polynucleotide difference spectra. ——, Free quinacrine 1.55×10^{-5} M; – – –, quinacrine 1.55×10^{-5} M and polynucleotide 3.1×10^{-4} M. *a*, Calf thymus DNA; *b*, poly(dAT); *c*, poly(dG) · poly(dC). Difference spectra were run on a Cary 14 spectrophotometer (dispersion = 20 A° mm^{-1}) using 1 cm cells at 23° C. The reference cell contained a concentration of polynucleotide equal to that in the sample cell which contained the quinacrine–polynucleotide solution. Identical maxima were observed for reference optical densities of 0.6 (slits, 1 mm) and 1.85 (slits, 2.5 mm).

TABLE 1 Fluorescence quenching of quinacrine and quinacrine/nucleic acid complexes by iodide ion

	Φ_F^f/Φ_F^{f+b}	τ, ns	$kq \times 10^{-9}$ corrected	$M^{-1}\,s^{-1}$ uncorrected
QAC	1	4	7.8	—
QAC + poly(dAT)	0.4	20	0.19	0.20
QAC + poly(dG)·poly(dC)	7	6	2.3	3.0
QAC + DNA	2.1	10	1.1	1.2

[QAC] = 2×10^{-5} M; P:D = 20:1. The solution was buffered at *p*H 7 with 0.01 M cacodylate. The ionic strength was maintained constant at 0.1 M by the addition of appropriate amounts of NaCl such that $[Cl^-] + [I^-] = 0.1$ M. The polynucleotides were purified by dialysis for 24 h. Calf thymus DNA was purchased from Worthington Biochemicals; poly (dG)·poly (dC) and poly (dAT) were purchased from Miles Laboratories. Fluorescence intensities were measured using a Farrand spectrofluorimeter exciting at 365 nm (bandwidth 5 nm) and monitoring at 490 nm. Lifetimes were measured by the TRW model 75A fluorescence lifetime apparatus. Rate constants were obtained from Stern-Volmer plots[23] of fluorescence intensity compared with [iodide]. Φ_F^f/Φ_F^{f+b} (=A) is the ratio of the quantum yield of the free dye to that of free + bound dye. The corrected rate constants were derived from values of I_b^0/I_b obtained according to[22]:
$I_b^0/I_b = [1 - (1 - \alpha)A]/[(I_f^0{}_{+b}/I_{f+b})^{-1} - (1 - \alpha)A(I_f^0/I_f)^{-1}]$
where I is the fluorescence intensity, the superscript zero designates the fluorescence at zero iodide concentration; the subscripts f, b, $f + b$ designate free dye, bound dye, and free plus bound dye respectively; α is the fraction of bound dye (0.95). I_{f+b} are the observed values of the fluorescence intensity at various iodide concentrations.

maxima which we have observed from the difference spectra as being due to two states formed from the dipole-dipole interaction between the S_3 state of QAC and the S_1 state of DNA with intensity being stolen from the intense $S_0 \rightarrow S_2$ transition of QAC. In the case of dipole-dipole interactions the interaction energy varies as r^{-3}. We conclude therefore that the binding of QAC to poly(dG)·poly(dC) and to the other two polynucleotides is such that the distance of approach between QAC and the G–C base pairs is much larger than that between QAC and the A–T base pairs. In this sense, the observed splitting in DNA and poly(dAT) and the limiting P:D ratio of 5 at which the splitting is observed is fully consistent with the intercalation model.

Since the more tightly wound G–C helix is less likely to unwind than the other two polynucleotides in order to accommodate the intercalating dye molecules, the different difference spectra observed for poly(dAT) and DNA dye complexes on the one hand, and the poly(dG)·poly(dC)–dye complex on the other supports the intercalation model in the former two polynucleotides.

The constant shape of the Franck Condon envelope of the difference spectra when the P:D ratio was varied from 50:1 to 5:1 demonstrates that the observed splitting results from highly localised interactions between dye molecules and their nearest neighbour. There is no evidence for dye-dye interactions in QAC-nucleic acid complexes.

This conclusion suggests that the dye is more sterically hindered, and hence more shielded from collisions with molecules in solution, when bound to poly(dAT) than when bound to poly(dG)·poly(dC). A test for this was to examine the quenching of the fluorescence of the complexed QAC molecule by species such as iodide ions—a collisional process[21]. We would expect differences in the fluorescence quenching rate constant (k_q) for QAC–poly(dAT) and QAC–poly(dG)·poly(dC) complexes. Fluorescence intensity values for quenching[22] are less physically significant than k_q, for they do not account for the significant variation in fluorescence lifetime of the dye in the different environments (Table 1).

In the three cases studied, Stern-Volmer[23] plots were linear. Table 1 shows a significant variation in k_q depending on the complex. We applied a correction[22] to the observed k_q values in order to ensure that the differences observed were not due to a small amount of free dye (estimated to be less than 5% from absorbance changes at 440 nm, compared with P:D) which may still be present even at high P:D ratios. There was no significant difference between the corrected and uncorrected values.

The value of k_q for the free dye agrees with the calculated diffusion controlled value in water[24]. The poly(dAT)–QAC complex had the lowest k_q and poly(dG)·poly(dC)–QAC complex the highest. These observations confirm our interpretation of the spectroscopic experiments described above; that QAC is bound considerably closer (intercalated) to A–T than to G–C base pairs in the polynucleotides.

In summary, (1) we have observed exciton-like splitting between the S_3 state of QAC and the lowest excited state of DNA and poly(dAT) with concomitant intensity redistribution but have not observed this effect with QAC and poly(dG)·poly(dC); (2) we conclude that QAC is bound closer to A–T base pairs (possibly by intercalation) than to G–C base pairs in polynucleotides; (3) the most important interactions responsible for the splitting are nearest neighbour interactions; (4) dye-dye interactions are negligible in QAC-nucleic acid complexes.

Coupled with theoretical calculations we believe that the exciton-like interaction could be quite important in unravelling the structures of acridine dye-nucleic acid and similar complexes as they occur in solution.

α-Hydrazino-ornithine blocks net synthesis of putrescine but not of RNA and DNA

THE polyamines spermine, spermidine and their precursor putrescine occur ubiquitously and in high concentrations in animals and plants[1]. Increased polyamine synthesis in animal cells and bacteria precedes or coincides with enhanced RNA formation, especially during growth stimulation, suggesting a close relationship[2]. Ornithine decarboxylase (ODC), a rate-limiting enzyme in polyamine synthesis, has an extremely short half life[3]. The early, large increase in its activity in all cases of rapid tissue growth examined suggests that the formation of its product, putrescine, triggers early enhancement of RNA synthesis during cellular growth. A critical test of this concept would be to block net putrescine and(or) polyamine synthesis selectively and determine whether nucleic acid synthesis is altered. Such a test might assess the role of putrescine as a potential modulator of growth in normal and neoplastic tissue.

α-Hydrazino-ornithine (HO) is a specific and potent inhibitor of ODC with *Ki* values of 0.5 μM and 2 μM for bacterial and mammalian enzymes respectively[4,5]. HO inhibits competitively with both the substrate ornithine and the coenzyme pyridoxal phosphate. HO is 100 times more potent an inhibitor of ODC than are other hydrazines and inhibits the pyridoxal phosphate-dependent glutamic acid and dihydroxyphenylalanine decarboxylases only 1% as efficiently as it inhibits ODC[4,5], indicating considerable selectivity for ODC. HO is relatively nontoxic, producing no gross behavioural abnormalities in rats in doses up to 2 g kg^{-1} (ref. 5). We now report that HO effectively blocks net putrescine synthesis in rat hepatoma cells (HTC) in culture and in the liver of intact rats. Doses of the drug which markedly reduce putrescine do not appreciably affect the synthesis of either RNA or DNA.

The growth stimulus produced when high density HTC cells were diluted with fresh medium led to a marked increase in putrescine (Fig. 1). This increase followed soon

TABLE 1 Effect of α-hydrazino-ornithine on DNA and RNA synthesis in rat tissues

Addition	DNA (c.p.m.) in HTC cells	RNA (c.p.m.) Intact liver	RNA (c.p.m.) Regenerating liver
None	19,700 ± 1,500 (n = 3)	1,290 ± 140 (n = 4)	1,610 ± 70 (n = 4)
α-Hydrazino-ornithine	20,600 ± 1,200 (n = 3)	1.200 ± 90 (n = 5)	2,250 ± 140 (n = 5)

HTC cells were collected and stimulated by dilution (1:5) with fresh growth medium in the presence and absence of α-hydrazino-ornithine (5 × 10^{-4} M). At 17 h, ^{3}H-thymidine (1 μCi ml^{-1}; 6–7 Ci mmol^{-1}) was added and incorporation into 5% trichloroacetic acid (TCA)-precipitable material was measured in 1 ml aliquots of cells (25 μg protein) after a 1 h pulse at 37°C (methods as in legend to Fig. 1). DNA incorporation is expressed as c.p.m. ± s.e.m. per sample. The incorporation of ^{14}C-orotic acid (6.6 mCi mmol^{-1}) into rat liver was measured in 5% TCA-precipitable material 10 min after intravenous administration of 1 μCi of orotic-6-^{14}C-acid[13]. α-Hydrazino-ornithine (200 mg kg^{-1}) was given subcutaneously to sham operated and hepatectomised animals at operation and 4 h later; animals were killed 7 h after hepatectomy. Hepatic tissue was excised, quick frozen, weighed and homogenised in 9 volumes of 0.32 M sucrose. Aliquots (0.5 ml) were precipitated by adding 0.3 ml of 20% TCA, and the precipitate was washed with four successive 4-ml portions of 5% TCA and two 4-ml portions of absolute methanol. The resulting precipitate was dissolved in 1 ml of hydroxide of hyamine at 70°C for 30 min and transferred with 1 ml of absolute ethanol to 10 ml of PCS solubiliser for scintillation counting. RNA incorporation is expressed as c.p.m. ± s.e.m. per sample (0.057 g wet weight of tissue).

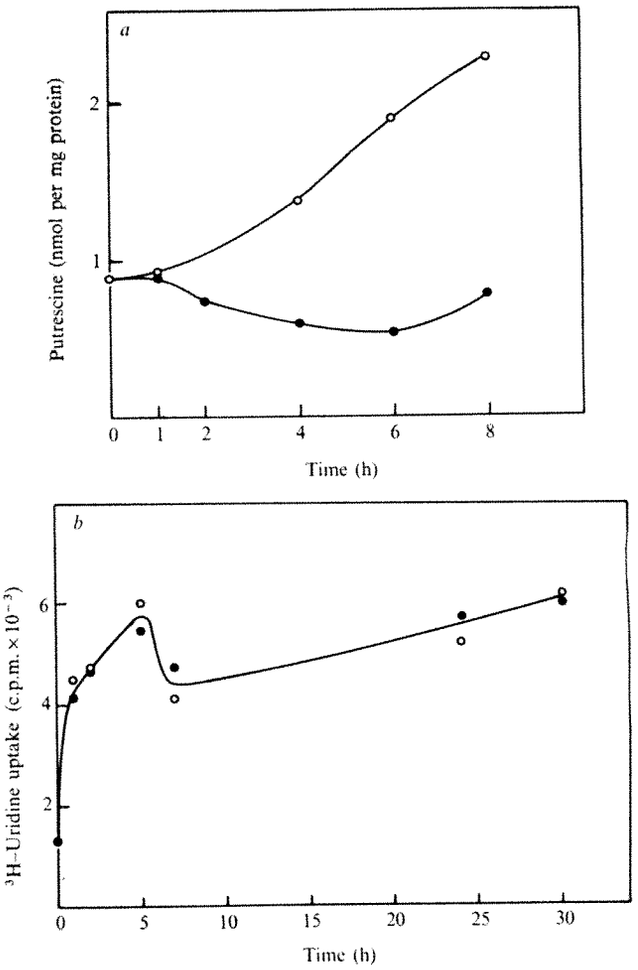

FIG. 1 Influence of α-hydrazino-ornithine on putrescine levels (*a*) and RNA synthesis (*b*) in HTC cells. *a*, HTC cells were grown to high density (about 2 × 10^7 per flask) in monolayer in 75 cm^2 Falcon flasks as described previously[8]. Cells were collected by scraping, and diluted (final concentration about 2 × 10^5 ml^{-1}) with fresh growth medium (10% foetal calf serum in Eagle's minimum essential medium with Hanks balanced salts, supplemented with 100 U each of penicillin and streptomycin, and equilibrated with 5% CO_2 in air). Putrescine was analysed by an enzymatic-isotopic microassay[14] in cell extracts. Aliquots (approximately 2.5 × 10^6 cells) were collected by centrifugation, washed twice at 4° with 10 ml phosphate-buffered saline, and disrupted by freezing and thawing four times in 0.25 ml distilled water. Protein was precipitated by heating at 95° C for 15 min and putrescine was assayed in the supernatant fluid. Results are expressed in nmol putrescine per mg cell protein, determined on aliquots of cell lysates by the method of Lowry *et al.*[15] *b*, High-density HTC cells collected by scraping were diluted 1:5 with fresh medium and incubated at 37° C in 1 ml aliquots (final concentration 2 × 10^5 cells per ml). ^{3}H-uridine (1 μCi ml^{-1}; 26 Ci mmol^{-1}) incorporation was measured by a 1 h pulse at timed intervals after dilution. Cells were washed by centrifugation at 4° C with three successive 5 ml aliquots of Hanks buffer, 5% TCA and absolute methanol. The final precipitate was solubilised in 0.5 ml of hyamine in methanol at 70° C for 15 min, and the solution was mixed with 3 ml of absolute ethanol for scintillation counting. Uridine uptake is expressed in c.p.m. incorporation per sample (average of triplicate samples). ○, Cells without α-hydrazino ornithine; ●, cells with 5 × 10^4 M α-hydrazino-ornithine.

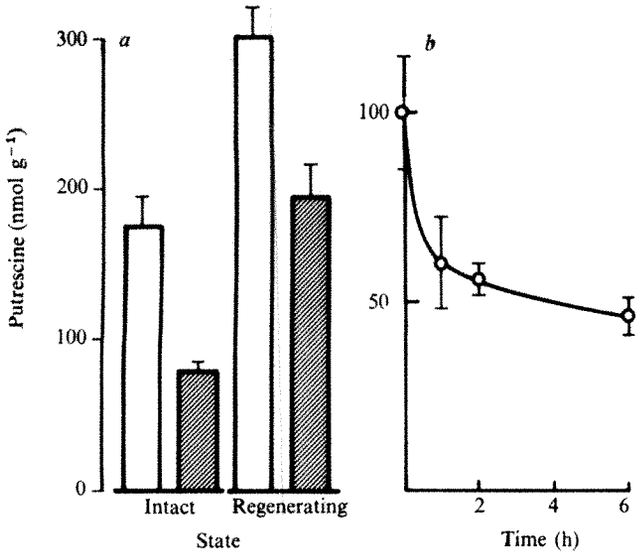

FIG. 2 Effects of α-hydrazino-ornithine on putrescine levels in intact and regenerating liver. *a*, Male rats (130 g, groups of three) under ether anaesthesia were nephrectomised bilaterally, with or without concomitant partial hepatectomy. Four hours after operation, animals received either saline (0.9% NaCl) or α-hydrazino-ornithine (75 mg kg^{-1}, subcutaneous), and were killed 2 h later. Livers were quick-frozen and tissue was homogenised in 9 volumes of distilled water. Protein was precipitated by heating for 15 min at 95° C and putrescine was measured in the supernatant[14]. Results are expressed in nmol of putrescine per g wet weight of tissue. Bars above the columns indicate s.e.m. *b*, Intact rats were killed at timed intervals after the subcutaneous administration of 200 mg kg^{-1} α-hydrazino-ornithine, and hepatic tissue was analysed for putrescine as outlined above. Results are expressed as nmol per g wet wt with vertical bars indicating 2 s.e.m. values. Open columns, saline; hatched columns, α-hydrazino-ornithine.

after that of ODC activity, which reached a maximum after 4–6 h and then declined[6–8]. In the presence of HO, putrescine levels not only stopped increasing, but they declined. In these cultures ODC activity is completely inhibited, although dialysis of tissue extracts to remove HO unmasks an enhancement of ODC levels[8]. The time course of incorporation of ^{3}H-uridine into high-density monolayer HTC cells diluted with fresh growth medium (Fig. 1) resembles that reported earlier for synchronised HTC cells in suspension[9]. It is interesting that the synthesis of RNA, as reflected by uridine incorporation, was virtually unaffected when putrescine levels were substantially lowered by HO. ^{3}H-uridine incorporation was unaltered in the presence of HO for periods up to 30 h. Because we did not measure specific activities of nucleotide triphosphate pools, changes in precursor uptake may have masked effects of HO on nucleic acid synthesis.

In agreement with previous studies on synchronised HTC cells in suspension[9], the high-density monolayer cells exhibited maximal ^{3}H-thymidine incorporation 18–20 h after stimulation by dilution with fresh growth medium. At this time there was no appreciable difference between cells stimulated in the absence or presence of HO (Table 1).

In intact animals HO depressed hepatic putrescine levels about 50%, an effect which persisted for at least 6 h (Fig. 2). In regenerating liver, HO prevented the 1.7-fold increase in putrescine usually elicited by partial hepatectomy[10,11] (Fig. 2). Hepatic putrescine levels were higher in controls, nephrectomised to impair HO excretion and permit administering lower doses, (Fig. 2, left) than in unoperated controls (Fig. 2, right), which is consistent with reports that stress increases hepatic ornithine decarboxylase activity[12]. In agreement with earlier data[13], partial hepatectomy caused a 25–50% increase in liver RNA synthesis, which is the same in nephrectomised and normal rats. In contrast to its influence on putrescine, HO (50 mg kg^{-1} to nephrectomised rats; 400 mg kg^{-1} to nonnephrectomised rats) failed to alter the apparent increase in RNA synthesis (Table 1).

Thus both in HTC cells in culture and in regenerating and intact rat liver, HO effectively blocks net putrescine formation. Neither RNA nor DNA synthesis is apparently altered in HTC cells, and RNA synthesis is unaffected in regenerating and intact liver. HO only partially lowered putrescine levels in our experiments. Conceivably, complete depletion of putrescine might affect nucleic acid formation. Moreover, more refined techniques may reveal influences of HO on the synthesis of certain classes of RNA or DNA. Although we did not measure spermidine and spermine, it is conceivable that their continued synthesis in the presence of HO could mediate enhanced nucleic acid synthesis. However, blockade of spermidine and spermine formation by methyl glyoxal *bis* (guanylhydrazone), which inhibits S-adenosylmethionine decarboxylase, fails to impair nucleic acid synthesis[16,17].

Our data indicate that enhanced ODC activity and putrescine formation are not an indispensable signal for new RNA and consequent DNA synthesis. Although increased levels of putrescine and presumably of polyamine formation may not be causally related to new RNA synthesis, the accumulated evidence[1,2] still suggests that the polyamines serve an important function in tissue growth.

Hormonal regulation of presumptive mRNA in the fungus *Achlya ambisexualis*

THE Oomycete fungus, *Achlya ambisexualis*, is one of the most primitive eukaryotes which differentiates in response to a steroid hormone[1]. Because it is fast growing, easy to manipulate and can be induced to undergo differentiation in a relatively synchronous manner (the entire thallus acts as target cells), *Achlya* lends itself to studies of the molecular control of gene activation by hormones.

Antheridiol, a sterol secreted by female strains of *Achlya* has been characterised from culture filtrates and synthesised from disnorcholenic acid[1]. The hormone is active at 6×10^{-12} g^{-1} when assayed with *A. ambisexualis* (strain E87)[1]. Addition of antheridiol to vegetative hyphae elicits the initiation of antheridial branches[2] which eventually differentiate into the male sex organs (antheridia). Thomas and Mullins[3] postulate that a prerequisite for hormonal induction of antheridial hyphae is a localised softening of the cell wall by cellulase. They suggest that this weakens areas of the walls, through which protoplasm is forced by the internal turgor pressure forming the sex organ initial. Their preliminary studies suggest that both transcription and translation are required for this process[4]. In animals steroid hormones can stimulate transcription of specific mRNAs which are then translated into proteins required for cellular differentiation[5–7].

Recent studies have shown that mRNAs of higher plants and animals contain a sequence of polyadenylic acid (poly(A)) which is added to the 3′ ends of the molecules[8–10]. Only histone mRNAs lack a poly(A) moiety[11]. We have demonstrated in *Achlya* the presence of a poly(A)-rich class of cellular RNA. This is the most primitive eukaryote to date in which poly(A) has been shown to be associated with presumptive mRNA. Furthermore, we have demonstrated that the sex hormone, antheridiol, has a considerable effect on the accumulation of this RNA during the early stages of male sex organ development. We have characterised the poly(A)-rich fraction and have demonstrated its similarity to the mRNAs of higher eukaryotes.

Poly(A)-rich RNA has been demonstrated in the cellular slime mould, *Dictyostelium discoideum*[12] and in the yeast, *Saccharomyces cerevisiae*[13,14]. The size of this poly(A) varies from 50 nucleotides in yeast[13] to more than 200 nucleotides in higher animals[15–17]. In contrast, *Escherichia coli* mRNA, so far as is known, does not contain any poly(A)[18]. Two interesting questions are (*i*) do all existing eukaryotes possess some poly(A) associated with their mRNA, and (*ii*) does the size of such poly(A) increase with phylogenetic complexity? We have found the size of the *Achlya* poly(A) moiety to be smaller than the poly(A) tracts found in animals and *D. discoideum* but similar to that of *S. cerevisiae*.

Stock cultures of *A. ambisexualis* were maintained on Emerson's YPSS agar (Difco). Asexual spores were prepared according to Griffin[19]. A suspension of 1×10^5 spore cysts was inoculated into PYG broth (300 ml)[19] and grown for 24 h at 23° C until a finely suspended mycelium had grown. This was stored at 5° C or used immediately as an inoculum. A 25 ml sample of this was transferred to flasks containing 275 ml of Barksdale's mating media[20] and was grown for 24–32 h at 23° C. Cultures were collected through four layers of cheesecloth followed by washing with four volumes of ice-cold deionised H_2O.

RNA was isolated at 5° C by suspending 10–20 g wet weight of mycelia in SSC (0.15 M NaCl, 15 mM Na-citrate, *p*H 8.3) 1% SLS (Na-lauryl sulphate) and an equal volume

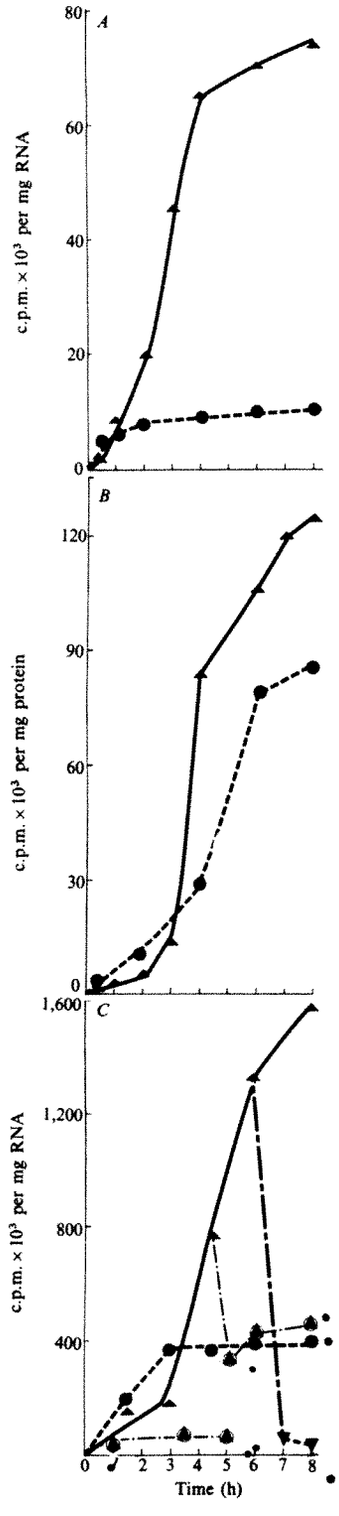

FIG. 1 The effect of antheridiol on the accumulation of RNA and protein during male organ initiation in *A. ambisexualis*. Total phenol-extractable RNA. Cells were exposed to continuous labelling conditions (10 μCi ^{3}H-uridine, specific activity 52 Ci mmol^{-1}) from time zero in the presence (▲) and absence (●) of 5×10^{-11} g ml^{-1} antheridiol. Concentration of RNA was determined by A_{260}/A_{280} ratios. Radioactivity was determined on a liquid scintillation counter. *B*, Total hot TCA-precipitated protein. Cells were labelled using steady state conditions (25 μCi ml^{-1} ^{3}H-leucine, specific activity 54 Ci mmol^{-1}) in the presence and absence of hormone. Concentration of protein determined by A_{280}/A_{260} ratios or by the Lowry procedure. *C*, Poly(A)-rich RNA accumulation. Cells were labelled using steady state conditions (10 μCi ml^{-1}) in the presence (▲) and absence (●) of hormone. Total RNA was extracted as described in the text and passed through a Sigma 38 cellulose column (Fig. 2). RNA concentration and radioactivity were determined as described above. When indicated 10 μCi ml^{-1} actinomycin D (– – –) (ref. 19) 25 μg ml^{-1} cordycepin (—•—) (ref. 9) was added to the hormone-treated cultures.

TABLE 1 Base composition analysis of *A. ambisexualis* RNA from unmodified cellulose columns

RNA fraction	Base composition (%) C	G	A	U
+ Hormone (bound)	17.3	21.5	33.5	27.5
Vegetative control (bound)	16.6	20.5	34.5	27.8
Unbound (both hormone and control)	17.4	23.1	29.4	29.9

Phosphorus-32 (15 μCi ml^{-1}, carrier free)-labelled RNA fractions were collected from Sigma 38 cellulose columns (Fig. 2) made up to SSC, 1% SLS, 0.3 M LiCl and precipitated in 2.5 volumes of ethanol. The precipitate was taken up in 0.3 N KOH and hydrolysed at 37°C for 24 h. Base composition was determined using descending paper chromatography following the procedure of Lane[25].

of phenol, equilibrated with 50 mM Tris-HCl, *p*H 8.3. The mixture was then homogenised in a Willems polytron homogeniser at the highest setting for 10 s. The aqueous phase was extracted three times with the Tris-washed phenol. This phase was made 0.3 M with respect to LiCl and the precipitated RNA was washed twice in ethanol, dried and dissolved in deionised H_2O.

To prepare partially purified nuclei, 30–50 g wet weight of tissue was suspended in SSC buffer containing 1% SLS, and 0.25 M sucrose according to the procedure of Jaworski and Horgen[21]. The nuclear pellet (containing some mitochondria) was resuspended in SSC, 1% SLS and extracted with phenol, precipitated with ethanol and taken up in deionised H_2O as described above. Polyribosomes were isolated according to the method of Lin and Key[22], except that buffers were at *p*H 9.0. Polysome fractions were pooled and the RNA was extracted as described.

In the presence of 5×10^{-11} g ml^{-1} antheridiol at 23° C, antheridial branch initials are visible between 3 and 4 h after the addition of hormone. The incorporation of ^{3}H-uridine into total phenol-extractable RNA is shown in Fig. 1*A*. The specific activity of the total RNA extracted from hormone-treated cells increased (after a lag of 30 min) markedly for 4 h, whereas control (vegetative) cell RNA reached a steady state 2-3 h after addition of the ^{3}H-uridine.

Figure 1*B* shows the effect of antheridiol on total protein accumulation. In the hormone-treated tissue a lag of 2-3 h was observed before the rate of incorporation of ^{3}H-leucine increased considerably. Conversely, incorporation of ^{3}H-leucine into protein in vegetative mycelia showed no detectable lag.

Total phenol-extractable RNA, from either the whole cell homogenate, nuclei or preparations of polysomes was passed through an unmodified Sigma 38 cellulose column[23], and the poly(A)-rich fraction was eluted with deionised H_2O (Fig. 2). The fraction eluted with H_2O (cellulose-bound) was found to be rich in adenylic acid (Table 1). The cellulose-bound fraction from both the hormone-treated and vegetative mycelia had greater than 33.5% AMP residues (Table 1). This was in contrast to the adenylic acid content found in the remainder of the cellular RNA. These values are similar to those reported for other enkaryotes[8,17].

The effect of antheridiol on the incorporation of ^{3}H-adenosine into poly(A)-rich RNA is shown in Fig. 1*C*. Antheridiol stimulated a three to four fold increase in the specific activity of the poly(A)-rich fraction after an initial lag period (2–3 h), whereas incorporation of label into the poly(A)-rich fraction of vegetative cells showed no lag, increased linearly, and reached a steady state after 3 h (Fig. 1*C*). The enhancement of incorporation between 3 and 4 h after addition of the hormone corresponds to the observation of the appearance of male sex organ initials. Addition of actinomycin D causes a rapid decline in the specific activity of the poly(A)-rich fraction within 1 h (Fig. 1*C*), suggesting that total poly(A)-rich RNA accumulation is affected by actinomycin D and that the life span of a given poly(A)-rich molecule is very short (less than 1 h). Cordycepin, a drug which is known to affect the post-transcriptional addition of poly(A)[9], rapidly inhibited the incorporation of ^{3}H-adenosine into *Achlya* poly(A)-rich RNA (Fig. 1*C*). This suggests that the mechanism for the addition of the poly(A) fraction to *Achlya* presumptive mRNA is similar to the mechanism operative in mammalian cells.

In order partially to insure that our incorporation studies were in fact measuring mRNA accumulation and not rapid changes in nucleotide pool sizes, we compared incorporation of label into poly(A)-rich RNA with the effect of antheridiol on leucine incorporation (Fig. 1*B* and 1*C*). Again, an enhancement of the total hot trichloroacetic acid (TCA) precipitable counts was observed when compared with the control. The rapid increase in specific activity of the total protein between 3 and 4 h corresponded to the rapid increase observed in total incorporation into poly(A)-rich RNA. These data indicate that antheridiol stimulates the accumulation and possibly the synthesis of an adenylate-rich fraction of cellular RNA. This enhancement of the total specific activity of the RNA fraction was observed whether the RNA was isolated from the total cell homogenate, from purified nuclei or from polyribosomes.

During male sex organ differentiation in *A. ambisexualis* (E87), the external morphogenetic stimulus, antheridiol, activates the accumulation of a class of RNA, presumably messenger, which is required for the initiation of the antheridial branches. The addition of actinomycin D and of cordycepin inhibits the accumulation of the messenger-like fraction and also prevents normal morphological differentiation. Similar stimulation of mRNA synthesis by oestrogen and progesterone has been reported during chick oviduct development[24].

If the poly(A)-rich RNA of *Achlya* is in fact mRNA, then it would be expected that differing size transcripts would be synthesised for differing size gene products. In an attempt to determine the relative size of the poly(A)-rich RNA from *Achlya*, polyacrylamide electrophoresis of the

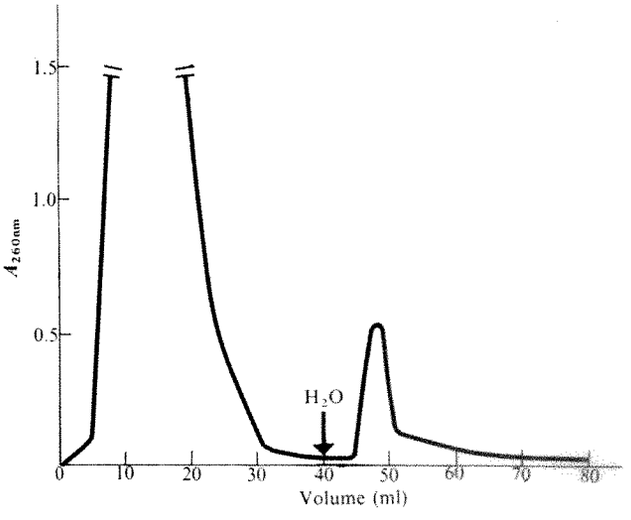

FIG. 2 Chromatography of *A. ambisexualis* RNA on Sigma 38 cellulose. RNA was extracted in SSC, 1% SLS precipitated in the presence of 0.3 M LiCl and taken up in deionised H_2O (1 ml). RNA concentration and radioactivity determined as in Fig. 1. The RNA was diluted to 10 ml with 10 mM Tris-HCl (*p*H 7.6), 500 mM KCl, 0.2 mM $MgCl_2$, and 400 A_{260} units were applied to a 3 ml cellulose column[23]. The column was washed with the above buffer until the A_{260} reading dropped below 0.02. Deionised water was then passed through the column to elute the poly(A)-rich RNA. This RNA was either used immediately or made up to SSC, 1% SLS and reprecipitated in ethanol.

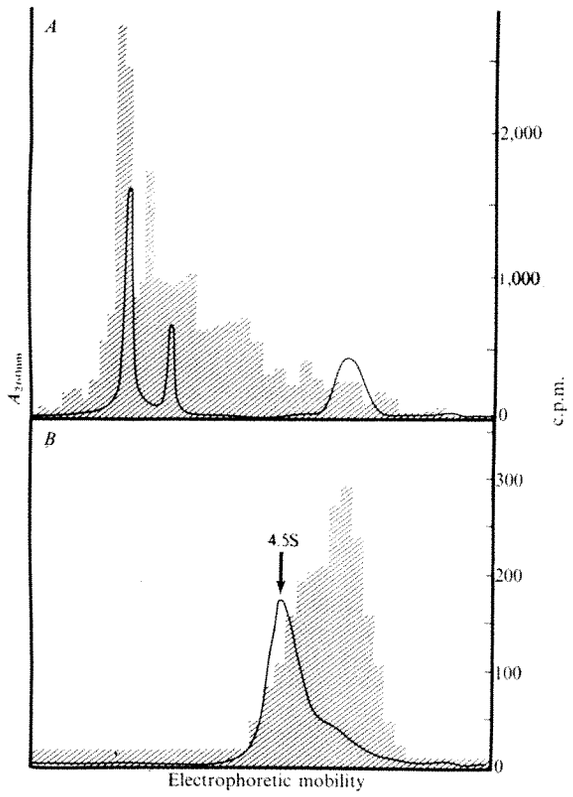

FIG. 3 Gel electrophoresis of *A. ambisexualis* poly(A)-rich RNA and RNAase digestion product. *A*, ^{3}H-adenosine-labelled poly(A)-rich RNA was isolated as described in Fig. 2 and reprecipitated with nonlabelled total *Achlya* RNA. Disc electrophoresis was performed using the procedure of Jaworski and Horgen[21] in 2.4% gels. The gels were scanned with a Gilford linear transporter, frozen in dry ice and sliced with a Mickle gel slicer. The slices were solubilised with NCS (Nuclear Chicago) and counted in a Beckman LS-150 scintillation spectrometer. *B*, ^{3}H-adenosine-labelled poly(A)-rich RNA was digested for 30 min at 37°C in 10 mM Tris-HCl (*p*H 7.6), 50 mM KCl, 1 mM $MgCl_2$ with pancreatic RNase (Worthington 56.8 μg ml^{-1}). The hydrolysed solution was reprecipitated in ethanol with 100 μg *E. coli* tRNA (4.5S). The precipitated polynucleotides were washed once in ethanol and taken up in electrophoresis buffer[21]. The mixture of tRNA and *Achlya* poly(A) was layered onto a 5% gel and electrophoresed for 2 h at 6 MA per gel. Gels were scanned, sliced and counted as above. Similar results were obtained when cells were pulse labelled for 2 h with 15 μCi ml^{-1} ^{32}P. RNA was extracted from the 5 h hormone-treated cells or from vegetative control cells that had been labelled for 5 h. Both gave identical gel profiles.

Sigma 38 cellulose-bound fraction with *Achlya* 26S, 18S, 5S and 4S RNA present as markers was performed. Figure 3*A* indicates that the poly(A)-rich fraction ranged from approximately 30S to almost 4S. These results are similar to what has been reported in other eukaryotic cells[16,17].

To determine the size of the poly(A) tract we took advantage of the fact that polyadenylic acid is insensitive to hydrolysis by T_1 and pancreatic RNase A[16,17]. After nuclease digestion and reprecipitation in ethanol, the *Achlya* poly(A) moiety was either subjected to alkaline hydrolysis or electrophoresis with *E. coli* 4.5S RNA as a marker.

In establishing if the RNase-resistant material of *Achlya* consisted of polyadenylic acid, it was subjected to base composition analysis after alkaline hydrolysis. The value for AMP was greater than 90%.

Coelectrophoresis with *E. coli* RNA showed that the poly(A) segment in *Achlya* migrated more rapidly than the 4.5S (25,000 daltons) marker suggesting a molecular weight of approximately 16–18,000 (Fig. 3*B*). This means that the poly(A) segment of *Achlya* presumptive mRNA is about 60 nucleotides long. This is significantly smaller than the poly(A) tract in animal mRNAs[9,15,16], somewhat smaller than that found in cellular slime moulds[12], but very similar to that reported for yeast[13,14]. It seems that evolution has resulted in progressively longer poly(A) pieces on the mRNA molecules in organisms with greater phylogenetic complexity.

The genus *Achlya* is a member of the most primitive group of eukaryotes that shows a developmental response to steroid hormones. We have demonstrated that in the male strain of *A. ambisexualis* (E87), associated with antheridiol stimulation of the development of sex organ initials, there is a corresponding effect of the hormone on the accumulation of a messenger-like fraction of RNA and on the accumulation of protein. These results suggest that the sterol affects morphogenesis by turning on the synthesis of mRNA which is then translated into protein required for the differentiation of the male sex organ initial.

We feel that *Achlya* provides a unique and valuable model system for the study of hormonal effects on development, both at the morphological and biochemical levels.

We thank Gary Craig and Robin Smith for technical assistance, Dr A. W. Barksdale for antheridiol and Dr A Guha for *E. coli* 4.5S RNA. This work was supported by grants from the National Research Council of Canada, and Research Corporation (Brown-Hazen) to P.A.H.

Serological evidence of calicivirus transmission between marine and terrestrial mammals

THE recent isolation of two serotypes of San Miguel sea lion virus (SMSV), a calicivirus indistinguishable from vesicular exanthema of swine virus (VESV), from California sea lions (*Zalophus c. californianus*) and Northern fur seals (*Callorhinus ursinus*) points to: (1) the widespread distribution of SMSV, and (2) the role of marine mammals as possible reservoirs of viral diseases of terrestrial animals[1,2].

The latter hypothesis has now been assessed further by a serological survey for SMSV neutralising antibodies in sea lion and fur seal sera, collected in 1972, and in feral swine sera obtained in 1973. Individual blood specimens were collected from twenty mature female California sea lions on San Miguel Island, one of the Channel Islands off the coast of southern California. Further specimens were obtained from 120 immature (3–4-yr-old) bachelor bull fur seals from four hauling grounds, Reef, Tolstoi, Lukanin and Zapadni during the annual seal harvest on St Paul Island, a member of the Pribilof Group of Alaska. Blood samples were collected from eighteen feral swine during the annual hunt on Santa Cruz Island, another of the Channel Islands. After processing, serum specimens were stored at −20° C until tested.

Vero cell monolayers, used for either neutralisation tests or production of SMSV viruses, were grown in Eagle's minimum essential medium (MEM) supplemented with 5% foetal calf serum and antibiotics (penicillin 200 U ml^{-1}; streptomycin 100μg ml^{-1}). Pools of the two serotypes designated SMSV-1MR and SMSV-2MR were produced by collecting inoculated Vero cell monolayers 18 h after infection and then titrating the supernatant fluids for 50% tissue infective doses ($TCID_{50}$ per 0.1 ml). The neutralising antibody test procedure was as follows. Serially diluted serum (inactivated by subjection to 56° C for 30 min) was mixed with equal volumes of virus suspension containing 100 $TCID_{50}$ per 0.1 ml, incubated at room temperature for 1 h, and 0.2 ml aliquots inoculated into each of four tubes of Vero cell monolayers per dilution tested. Inoculated tubes were then incubated stationary at 37° C and examined for cytopathic effect after 24, 48 and 72 h.

All twenty of the female sea lions had neutralising antibody titres to SMSV-2MR and eighteen had antibodies to SMSV-1MR (Table 1). The two distinct SMSV serotypes were isolated originally from different sea lions sampled on the same day. This together with serological evidence of SMSV antibodies against both isolates, confirms the simultaneous presence of two SMSV serotypes within the herd. This is not regarded as unusual for VESV; outbreaks have been reported where different VESV serotypes, attributed to mutation[3], occurred in the same domestic swine herd within a short time.

In contrast to the findings in sea lions, no serological evidence of SMSV-1MR antibodies was found in northern fur seals on St Paul Island. This is puzzling because a virus serologically identical to SMSV-1MR was isolated from an emaciated pup from the Reef rookery on this island[2]. One possible explanation is that the serum tested in our study was collected from 3–4-yr-old bachelor bulls who, due to their social behaviour, remained isolated from breeding adults and newborn pups. This would suggest that SMSV-1MR has been introduced recently into the fur seal herd on the Pribilof Islands.

One-third (40/120) of the fur seal sera tested had neutralising activity against SMSV-2MR (Table 1). Animals with antibody titres were from all four of the hauling grounds sampled. Although SMSV-2MR has not yet been isolated from any fur seals, serological evidence points to its past occurrence in the herd. It is important, however, that the same serotype of SMSV infected herds of two pinniped species as far apart as the Santa Barbara Channel and the Pribilof Islands. The annual fur seal migration from islands in the Bering Sea to waters off the coast of southern California and the presence of a small fur seal rookery on San Miguel Island, may account for the interspecies spread of SMSV.

TABLE 1 SMSV neutralising antibodies in sea lion, fur seal and feral swine sera

Antigen	Antibody titres	California sea lion (20)*	Northern fur seal (120)*	Santa Cruz feral swine (18)*
SMSV-1MR

	320	1	0	0

* No. of animals tested.

Feral swine on Santa Cruz Island have also had experience with the same SMSV serotypes; five out of eighteen serum specimens tested had SMSV-2MR and one out of eighteen had SMSV-1MR neutralising antibodies. Wild swine have existed on the Channel Island for many years, where they could have made contact with pinnipeds by foraging on beaches or scavenging on carcasses. The presence of antibodies in swine sera indicates that viral transmission has occurred. The age of the swine sampled was unknown, but their weight showed that only heavier, presumably older, animals had neutralising antibodies.

The finding of SMSV antibodies in feral swine and marine mammals may throw light on the successive outbreaks of VES in 1932, 1933 and 1934 in domestic swine[4]. The isolation of SMSV and its endemicity in pinniped herds suggests that VES outbreaks in domestic swine herds originated from a marine source. This coupled with the observation that SMSV produces a vesicular disease characteristic of VES in swine[5], and the finding of similar vesicles on fur seal flippers further substantiates inter-species transmission from a marine to a domestic animal[5,6]. Thus an exotic disease of swine thought to have disappeared 17 yr ago is now believed to have been rediscovered in pinnipeds and certain feral swine.

This research was supported through a contract between the Office of Naval Research and the Regents of the University of California. We thank the personnel of the Channel Islands Field Station for help in collecting specimens and H. Bray and D. Shilling for technical assistance.

Distribution of adenosine triphosphatase during anaphase in cricket primary spermatocytes

THE idea that an adenosine triphosphase (ATPase) may be involved in the generation of the force that moves chromosomes comes by analogy with other motile systems[1]. In striated muscle, the ATPase is a part of heavy meromyosin[2]. It forms cross bridges with actin filaments, and is an irreducible component in the mechanochemical process[3]. ATPase is also present in nonmuscular systems, such as slime moulds[4], myonemes[5], cilia and flagella[6–8], where it is essential for motility[9–10].

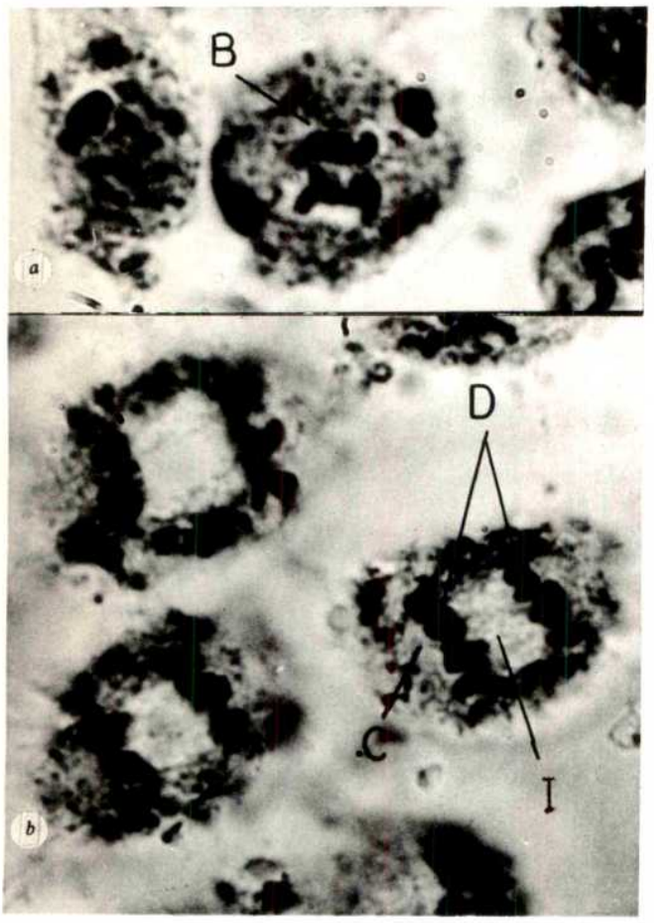

FIG. 1 The cytochemical distribution of ATPase in metaphase and anaphase primary spermatocytes from *Acheta domesticus*. ATPase is present in the stained areas (× 2,000). *a*, Metaphase: the stain is equally distributed in the cytoplasm and spindle, but heavier deposits occur in the bivalents (B). *b*, Anaphase: stain is absent in the interzone (I) between the separating dyads (D) but present in the chromosomal fibre regions, (C).

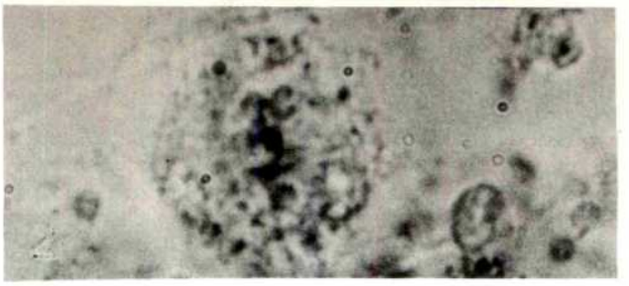

FIG. 2 Primary spermatocyte, metaphase, control: no stain is deposited in the spindle or cytoplasm (× 2,000).

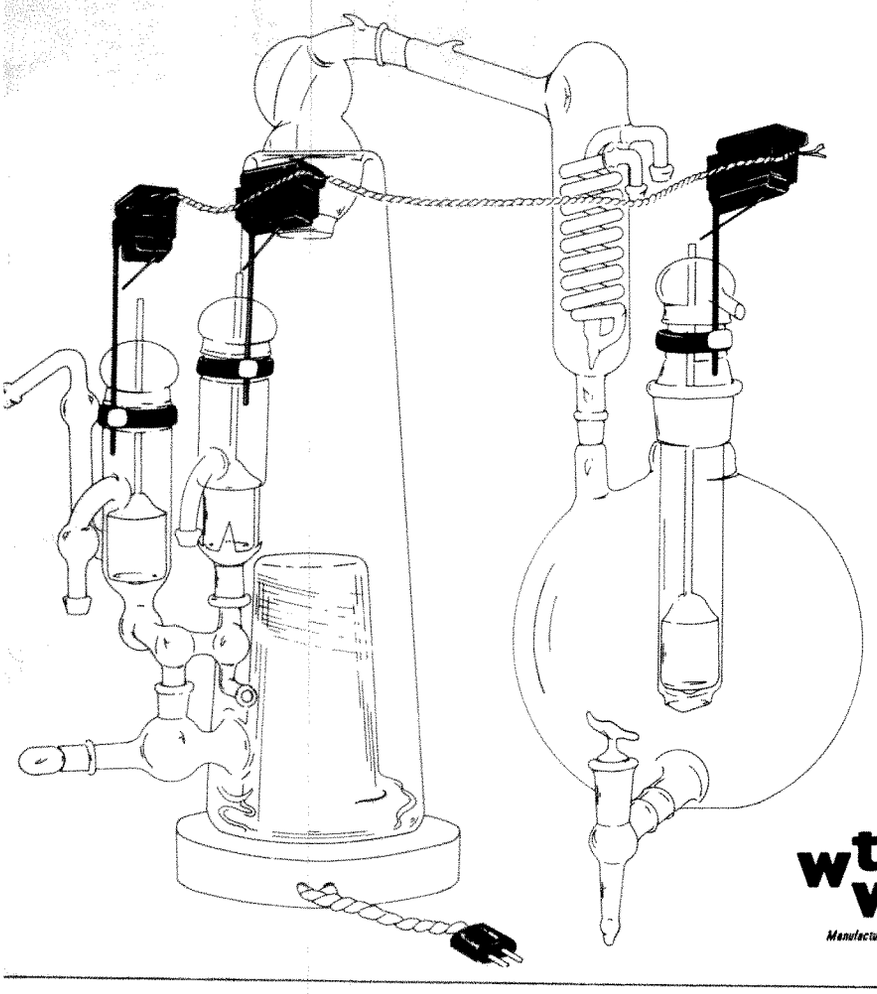
An ATPase has been found in spindles isolated from sea urchins[1,10–11], but it is difficult to decide whether the enzyme has a functional role or is a contaminant, for the very low specific activity present in the spindle is the same as that in the cytoplasm[11]. Other problems, such as the lability of the enzyme[12–13], or the possibility that the spindle's force-producing mechanism is solubilised during isolation[14] add to the difficulties. Furthermore, information necessary for the interpretation of spindle ATPase function cannot be detected in bulk spindle isolates. Such information would concern possible changes in the distribution of the same amount of enzyme within the spindle accompanying chromosome motion. A cytochemical approach to this problem, using spermatocytes of the domestic cricket *Acheta domesticus*, L., now indicates that the distribution of ATPase at anaphase differs from that at metaphase.



We cultured spermatocytes as described before[15], except that gelatin was incorporated into the medium to make the cells adhere to the coverslip to prevent their loss during cytochemical procedures. (A detailed account of the use of gelatin will be given elsewhere.)

When the cultures were established, they were observed until the cells reached the desired stage of division. Then the coverslips bearing the cultures were immersed in a fixative containing: 1 part 2.5% glutaraldehyde and 0.002 M $CaCl_2$ in 0.03 M cacodylate buffer (*p*H 7.2); 9 parts 2.5% hydroxyadipaldehyde in 0.55 M sucrose buffered with 0.03 M cacodylate (*p*H 7.5). After 12 min coverslips were washed once in buffered sucrose (0.03 M cacodylate and 8.5% sucrose) at 0° C and *p*H 7.4 and then given two 10-min rinses in buffered sucrose at *p*H 4.0 (to remove soluble phosphate). They were stored overnight at 6° C in the buffered sucrose, *p*H 7.4.

The fixed spermatocytes were treated by a modified Padykula–Herman method[17]. Incubation in substrate medium was at 37° C for 1 h. To test substrate specificity, ATP was replaced by 1.4×10^{-3} M ADP, GTP or ITP.

After the cytochemical procedure cultures were mounted in glycerol and ringed with clear nail polish. Controls were parallel cultures incubated without substrate. Sulphydryl dependence was tested by incubation in cysteine-free medium containing 0.01 M *p*-hydroxymethyl benzoate (POHMB). Enzyme localisation was considered positive when a black stain was present after incubation in medium containing substrate but was not present in control medium (Fig. 2).

Figure 1 shows the ATPase distribution. In the metaphase primary spermatocyte (Fig. 1*a*) both the cytoplasm and the spindle area stained with the same intensity. The chromosomes and the Golgi, however, stained more heavily. When spermatocytes were in anaphase (Fig. 1*b*), the stain was not equally distributed throughout the spindle area—there was a clear area in the interzonal spindle region, between the separating dyads. The stain, however, remained

The SCORAH Automatic Electric all glass WATER STILL (patented)

Automatic Can be left on without attention. Heater current cuts off if water supply is interrupted, or inadequate or forgotten. When receiver (5 litres capacity) is full, current cuts off. When distilled water is drawn from receiver, the still resumes operation until receiver is refilled.

Purity Electrostatically charged condenser droplets can pick up fumes, dust and air-borne organisms from the laboratory atmosphere. The design of the receiver vessel ensures absence of such contamination.

Efficiency Heater of Scorah design and manufacture, consumption 1,700 watts, output 2.4 litres per hour (the full theoretical yield). Cost less than 2p per gallon at ½p per unit.

Safety The heating element is out of contact with the feed water, thus eliminating danger from "live" water supply or electrolytic effects or "burn out".

Assembly No retort stands or clamps are required. The 2½-in. diameter ball joint gives a strainless set-up. Outlet cap on boiler for quick periodical drain-off of sediment. The still may be installed on a shelf or platform about 1 ft. above bench level near a sink and enclosed in a transparent plastic cover to keep out dust.

Heat-resisting glass. Interchangeable ground glass joints.

Sodium metrizoate

For isolation of leucocytes, thrombocytes, and other whole cells by flotation and gradient centrifugation.

Available as 32.8 % (ρ = 1.200 g/ml) and 75 % solution of SODIUM METRIZOATE✦.
(✦main component of ISOPAQUE®, TRIOSIL® and RONPACON®).

Meglumine metrizoate

For discontinuous and linear gradients in the isolation of bacteria, bacterial spores, viruses, spermatozoa as well as subcellular organelles.

Available as 76 % (containing 10 % sodium salt) solution of MEGLUMINE METRIZOATE.

Lymphoprep

For preparation of pure lymphocyte suspensions in tissue typing, anti-lymphocyte sera production and immunological research.

A ready made mixture of SODIUM METRIZOATE and FICOLL®✦ with density 1.077 ± 0.001 g/ml.
✦ From Pharmacia Fine Chemicals.

Metrizamide

A non-ionic, inert and easily watersoluble compound forming dense solutions of low viscosity. For gradient isolation of cells, viruses, subcellular particles and for isopycnic banding of biological macromolecules.

Available as dry substance in packages of 50 g.

INSTANT OCEAN®

Puts Life Into Marine Studies

New 50 gallon culture system — **Model CS-50**

Bring biology, physiology, embryology, etc., studies to life in your classroom ... right from the sea. Instant Ocean Culture Systems and Instant Ocean Synthetic Sea Salts provide a truly controllable environment, supporting the most delicate marine organisms... permitting complete life cycle studies.

This advanced design is made for teaching, laboratory, or display purposes. Just fill with water, add Instant Ocean Sea Salts, plug in, and add the animals. It's that simple! Instant Ocean Culture Systems are trouble free.

WRITE FOR DETAILS TODAY!

FREE with each Instant Ocean Culture System — Experiments Using Marine Animals by Dr. F. A. Diehl, et. al. A complete laboratory course using marine animals to show biological functions.

Fine Chemicals

in the chromosomal fibre region between the kinetochores and poles, and in the cytoplasm adjacent to the interzone. This difference in enzyme activity between the interzone and chromosomal fibre region persisted until the end of anaphase. The same pattern was found in secondary spermatocytes—equal distribution of enzyme activity between spindle and cytoplasm in metaphase and absence of activity in the interzone at anaphase. The stain remained undiminished in the chromosomes and other organelles. In control preparations, there were no differences between the interzones and half spindles under either bright field or phase contrast microscopy. With ADP (Fig. 3*a*), GTP (Fig. 3*b*) or ITP, both the interzone and the chromosomal fibre regions were stained in anaphase. In the presence of POHMB, the whole cell was more lightly stained and the degree of contrast between chromosomal fibre regions and interzones was reduced markedly (Fig. 4*a* and *b*). The Golgi, however, seemed to be unaffected by the presence of this sulphydryl inhibitor.

These observations on metaphase spermatocytes are consistent with those from the sea urchin[11], in that the ATPase was distributed equally between the spindle and the surrounding cytoplasm. They are not consistent with our failure to detect activity in spindles of root tip meristems[17]. This may reflect a difference in the two kinds of spindles (polar compared with apolar). But we used frozen sections of root tips, and have now determined that freezing denatures ATPase in spermatocytes. Thus our findings with root tips may have been artefacts.

The differences we observed in the anaphase distribution of ATPase were probably not a direct result of poor fixation of the interzone. Activity was evident in the interzone when nucleotide triphosphates other than ATP were used, and the interzone seemed to be morphologically intact when controls were viewed under phase contrast microscopy. We cannot, however, rule out the possibility that the ATP solubilises the interzone.

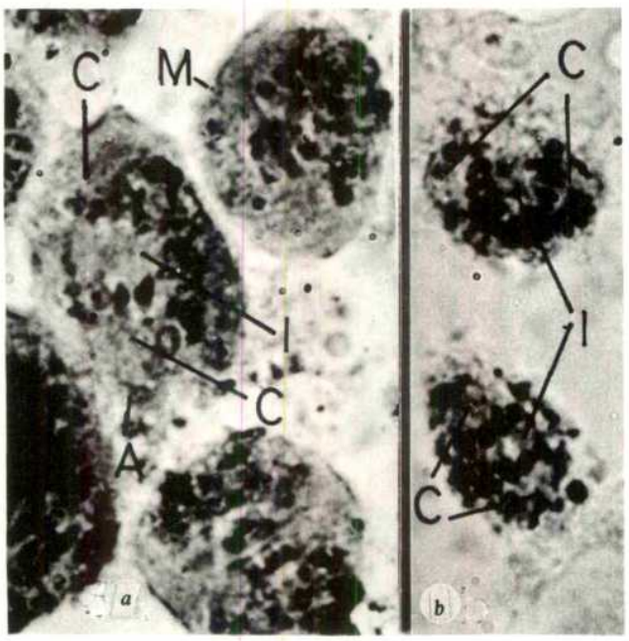

FIG. 3 The distribution of stain during anaphase when ADP and GTP replace ATP as substrate (× 2,000). *a*, ADP: primary spermatocytes, metaphase and anaphase. The stain is deposited in the interzone (I) and in the chromosomal fibre (C) regions of the anaphase cell (A). In the metaphase cell (M) the stain is evenly distributed in the cytoplasm and spindle area. *b*, GTP: secondary spermatocytes. The stain is present in the interzone (I) and chromosomal fibre (C) regions during anaphase.

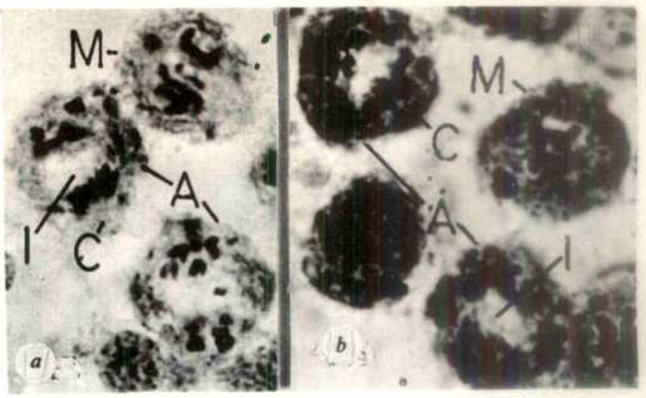

FIG. 4 Inhibition of ATPase by POHMB in metaphase and anaphase primary spermatocytes (×1,000). *a*, An ATPase determination in the presence of POHMB. Compare with (*b*). *b*, The control for (*a*). Cytochemical ATPase determined at the same time as (*a*) but without the inhibitor. The stain deposits are darker.

On the other hand, several facts suggest that the observed distribution of ATPase has functional significance. Thus, ATPase is present chiefly in the chromosomal fibre regions which are thought to generate the polarised forces to move the chromosomes or nonkinetochoric materials in anaphase[18,19]. Furthermore, ATPase is absent from the interzonal spindle, where significant polarised forces are not detectable at anaphase[18,19], and its distribution in metaphase and anaphase follows the changes in birefringence believed to coincide with the production of spindle force[20].

The spermatocyte ATPase is sulphydryl dependent, as is heavy meromyosin[21]. Actin-like filaments have been demonstrated in the spindles of grasshopper spermatocytes[22], and in the spindles and cortex of crane fly spermatocytes[23,24]. During anaphase these filaments are aligned parallel to the chromosomal fibres, but in the interzone they have a random orientation. Such orientation of actin filaments coincides with the reported distribution of ATPase and may explain the organisation of the ATPase in the chromosomal fibre region. If this were the case, then the interaction of actin and ATPase may be sufficient to generate forces that impart anaphase motion to chromosomes, and polarized motion to nonkinetochoric materials.

Temperature immutability of adenyl cyclase-coupled β adrenergic recptors

OBSERVATIONS from several laboratories have suggested that the well established classification of adrenergic receptors into α and β subtypes is not immutable. Several groups have reported that in isolated perfused frog hearts, stimulation of cardiac rate and contractility by catecholamines has the properties of a classical β adrenergic response when experiments are performed at warm temperatures (25°–37° C) but of an α adrenergic response when experiments are performed at cold temperatures (5°–15° C)[1–3]. At warm temperatures, the order of potency of agonists in stimulating these preparations—isoproterenol>adrenaline>noradrenaline—is classical for a β adrenergic receptor. Similarly, effects of the catecholamines at warm temperatures are blocked by propranolol but not by the α adrenergic antagonist phentolamine. When the same experiments are performed at temperatures below 25° C, the order of potency of agonists is reversed to that characteristic of α adrenergic receptors. Also at lower temperatures α adrenergic antagonists such as phenoxybenzamine and phentolamine block the effects of adrenaline, whereas β adrenergic antagonists such as propranolol are ineffective. Gradations of response can be achieved by varying the temperature between 37° C and 10° C. Similar observations have been reported for the rat heart[1]. Also in a dog heart–lung bypass preparation the β receptors seem to become ineffective at 15° C, whereas α receptors retain their effectiveness[4]. On the basis of such observations, Kunos *et al.*[3] proposed that α and β adrenergic receptors may represent allosteric configurations of the same receptor macromolecule which could be modulated by among other factors, temperature.

During the past decade, many observations have supported the concept that the adenyl cyclase system in various tissues provides an excellent biochemical model for study of the molecular properties of β adrenergic receptors[5]. In almost all situations where adenyl cyclase is stimulated by catecholamines, the properties of this stimulation are those of β adrenergic receptors. Of course, virtually all experiments which have been reported have been performed at temperatures within the range of 30°–37° C. If, in fact, α and β adrenergic receptors merely represent temperature sensitive transitions in the state of a single macromolecule, then the ability of catecholamines to stimulate and of adrenergic antagonists to block stimulation of adenyl cyclase should vary with temperature in a fashion analogous to that reported above. Accordingly, we have tested the ability of α and β adrenergic agonists and antagonists to stimulate and respectively block stimulation of adenyl cyclase in several tissues from cold-adapted frogs, as well as from the hearts of several mammalian species, using a wide range of temperatures. Our findings do not support the contention that the adenyl cyclase-coupled β adrenergic receptors are easily convertible to α adrenergic receptors when the temperature varies.

Table 1 summarises results from several experiments performed with membranes prepared from dog and rat heart. In each case, stimulation of the adenyl cyclase activity by catecholamines had the characteristics of a β adrenergic response at high (37° C) and low (15° C) temperatures. The β antagonist propranolol was an effective inhibitor of catecholamine-induced stimulation of the enzyme and the α adrenergic antagonist phentolamine was ineffective under all the conditions examined.

We next examined preparations from frog heart, since most of the evidence supporting the hypothesis of temperature conversion of β adrenergic receptors was obtained in this tissue. We had limited success however; using various conditions, we could demonstrate only marginal stimulation of the adenyl cyclase activity by catecholamines in preparations of frog heart membranes.

But because the frog, which is cold blooded, seemed the most appropriate animal in which to test the possibility that the two forms of receptors are interconvertible, we have examined the properties of the adenyl cyclase-coupled adrenergic receptors present in the frog erythrocyte. These are known to be typical β adrenergic receptors[8].

As Figs 1 and 2 show, whether incubation was at 37° C or 10° C the stimulation of the frog erythrocyte cyclase was mediated by classical β adrenergic receptors. The order of potency of agonists was isoproterenol>adrenaline>noradrenaline>phenylephrine. Moreover, the stimulation of the enzyme by catecholamines could be blocked effectively by propranolol, a β adrenergic antagonist, whereas the α adrenergic antagonist phentolamine was virtually without effect. Similar findings were obtained with both summer and winter frogs, either warm or cold adapted.

TABLE 1 Effects of α and β adrenergic agonists and antagonists on adenyl cyclase activity of canine and rat heart membranes at different temperatures

Additions		Adenyl cyclase activity (pmol cyclic AMP generated)			
		Dog heart membranes		Rat heart membranes	
Agonist	Antagonist	37°C	15°C	37°C	15°C
None	None	63.0	51.8	23.1	15.2

Ventricular myocardium (0.8 – 1.0 g) was homogenised in 20 ml of 0.25 M sucrose, 0.05 M Tris-HCl, *p*H 7.4 by ten strokes of a motor driven Potter–Elvehjem glass Teflon homogeniser. After filtration through cheese cloth, the homogenates were centrifuged in a Sorvall RC2B centrifuge for 10 min at 10,000*g*. Pellets were washed twice with the sucrose buffer and once with 75 mM Tris-HCl 25 mM $MgCl_2$, *p*H 7.4, before being assayed for adenyl cyclase activity. Adenyl cyclase was determined using a modification[6] of Krishna's method[7]. Incubations were for 10 min at 37°C and for 30 min (canine heart membranes) or 60 min (rat heart membranes) at 15°C. Enzyme activity was linear for these periods of incubation at both temperatures. Reaction mixtures contained the following reagents in a total volume of 50 μl: 25 mM Tris-HCl, *p*H 7.4; 10 mM $MgCl_2$; 1.5 mM ATP; 49–59 μg of membrane protein; 0.1 mM cyclic AMP and an ATP regenerating system consisting of 5 mM phosphoenolpyruvate, 40 μg ml^{-1} pyruvate kinase and 20 μg ml^{-1} myokinase. Agonists and antagonists were added to a final concentration of 4×10^{-6} M. The values shown are the mean of duplicate determinations.

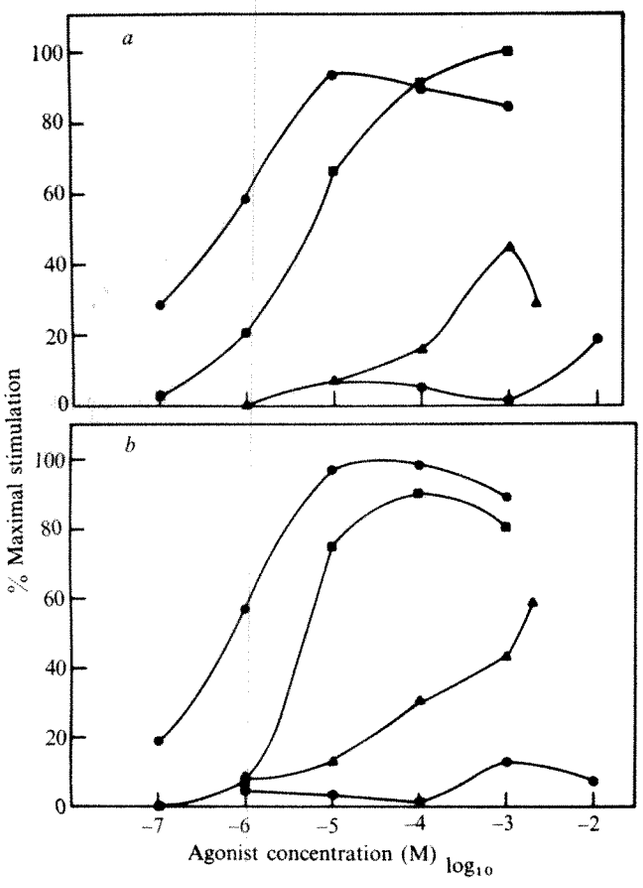

FIG. 1 Response of frog erythrocyte adenyl cyclase to adrenergic agonists at (*a*) 37°C and (*b*) 10°C. Isoproterenol (●), adrenaline (■), noradrenaline (▲) and phenylephrine (◆). Blood from cold-adapted southern jumbo grass frogs (Carolina Biological, Burlington, North Carolina) was collected and the red cells were washed three times with saline. Cells were lysed in 5 mM Tris-HCl, *p*H 8.1, buffer and the membranes were centrifuged at 18,000*g* for 15 min. The lysis process was repeated three times. Membranes were finally suspended in 75 mM Tris-HCl, 25 mM $MgCl_2$, *p*H 8.1 by homogenisation. Adenyl cyclase was assayed as described in Table 1, except that assays were carried out at *p*H 8.1 for 15 min at 37°C and for 60–90 min at 10°C. Cyclase activity was linear during these periods of incubation at both temperatures. Each sample contained 240–560 μg of membrane protein. In these experiments the mean basal enzyme activity was 285 pmol per mg protein. Maximal stimulation refers to activity observed in the presence of a maximally effective concentration of catecholamine which was generally about five times the basal activity. Each value is the mean of four determinations.

These findings suggest that the adrenergic receptors coupled to adenyl cyclase in mammalian heart as well as in frog erythrocytes are typical β adrenergic receptors, the characteristics of which are not altered at a wide range of temperatures. These observations do not seem to support the previous physiological observations reported and the hypothesis that β adrenergic receptors are convertible to α adrenergic receptors when temperatures are lowered, especially in the tissues of the cold-adapted frog. It should be noted that we were unable to test specifically the validity of the hypothesis for the frog heart, the tissue for which the most data has previously been reported. We cannot explain why only a marginal stimulation of frog myocardial cyclase activity was observed with catecholamines. As noted above, however, comparable changes in the specificity of the adrenergic receptors with temperature variation have been reported for rat heart[1]. In rat heart membranes, we saw no alteration in the adenyl cyclase-coupled β adrenergic receptors when the temperature was lowered.

Our observations raise objections to the hypothesis[2] that α and β adrenergic receptors are, in general, easily convertible allosteric forms of the same macromolecule. Although our data do not specifically disprove the hypothesis for the limited case of the frog heart, they do negate the hypothesis for the adenyl cyclase-coupled β adrenergic receptors of another frog tissue, the erythrocytes, as well as the mammalian heart in several species. It should be noted that whereas previously reported studies involved intact tissue preparations, our results were obtained exclusively with subcellular membrane fractions. Thus, it is possible that the apparent discrepancies in the results are due to a requirement for an intact cellular structure to mediate the changes in receptor specificity. The mechanisms involved in such an effect, however, are not clear.

It has not been shown definitively that β adrenergic effects on the myocardium are mediated by adenyl cyclase and cyclic AMP[9]. Moreover, the function of the frog erythrocyte β adrenergic receptors is not known. Nonetheless, as demonstrated here, the receptors which mediate effects of catecholamines on adenyl cyclase in each of these tissues are clearly β adrenergic receptors and hence represent a valid biochemical model of β receptors for studies such as these.

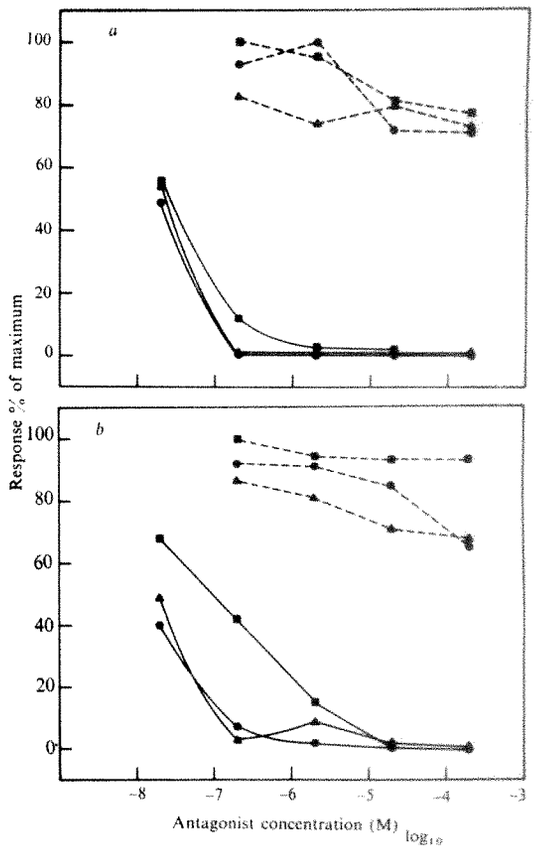

FIG. 2 Inhibition of catecholamine-induced activation of frog erythrocyte adenyl cyclase by adrenergic antagonists at (*a*) 37°C and (*b*) 10°C. Propranolol (———); phentolamine (– – – –). The agonists were present at the following concentrations: isoproterenol, 1×10^{-6} M (●); adrenaline, 1×10^{-5} M (■) and noradrenaline $1\text{–}5 \times 10^{-5}$ M (▲). Methods of membrane preparation and adenyl cyclase assay are described in the legend to Fig. 1. Incubations were carried out at 37°C for 15 min and at 10°C for 90 min. Each assay contained 250–310 μg of membrane protein. Maximum response refers to enzyme activity, in the presence of each agonist, at the stated concentration. 0% maximum response refers to activity in the absence of agonist, that is basal enzyme activity. In these experiments the mean basal activity was 207 pmol per mg protein and the concentration of agonists used gave usually a two to three-fold stimulation over basal activity. The results shown are the mean of four determinations.

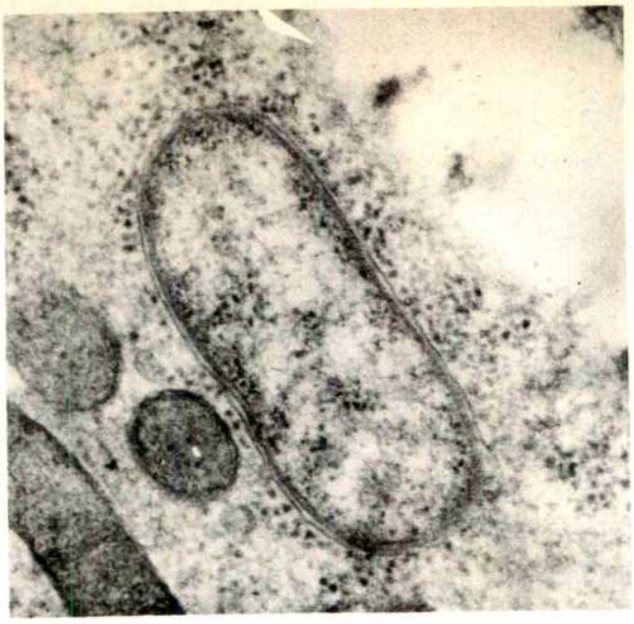

FIG 2 A bacteroid in the ooplasm of an actively vitellogenic oocyte from the active ovary of a female 4 d after emergence. Note the fibrils and ribosomes in the bacteroid. (× 54,500.)

Bacteroids in the ovaries of a tsetse fly

SYMBIONTS of *Glossina* previously described by Wigglesworth[1] as Gram-negative intracellular bacteroids are located in a group of specialised cells, the mycetome, in the midgut. Their intracellular nature is well known from studies with the light[1–3] and electron[4] microscopes (see Fig. 4). Roubaud[3] demonstrated bacteroids in the mycetome of the larval midgut of *G. palpalis*. He was unable to determine the mode of transmission, but suspected the involvement of the milk gland, as have other authors[5,6]. Recent work on the ultrastructure of the milk gland has demonstrated that bacteroids occur extracellularly in the lumen of the gland[7], thus adding support to the notion that transmission from one generation to the next may occur through the secretions of the milk gland. Bacteroids have not, however, been located in the cells of the milk gland, and it remains uncertain whether this route of transmission is used.

We report here for the first time the presence of intracellular bacteroids in the ovary of *G. austeni*, and suggest that their presence indicates the transovarian transmission of symbionts found in the larval and adult mycetome.

The ovaries of mated *G. austeni*, reared by the procedure of Tobe and Davey[8] were fixed[9] on the day of emergence and every second day thereafter up to 28 d after emergence, thereby spanning two pregnancy cycles. Both ovaries of two or three flies were fixed at each time, and tissues were embedded in Epon-Araldite[10]. Sections were cut on an LKB ultratome using glass knives, collected on uncoated copper grids, stained with uranyl acetate and lead citrate and examined in a Zeiss EM9S electron microscope.

Bacteroids were present in the cytoplasm of oocytes (Figs 1 and 2) and nurse cells (Fig. 3) of the ovary throughout the reproductive cycle. Similar bacteroids were seen occasionally in follicle cells and sheath cells of the ovary. Their surface structure and internal morphology resemble Gram-negative bacteria[11]. They are oblong, approximately 2 μm long, and contain a fibrillar network and ribosomes. They are bounded by a plasmalemma, an intermediate layer, and an outer double membrane. In addition, a host cellular membrane surrounds the whole structure (Figs 2 and 3). Dividing bacteroids were sometimes observed (Fig. 1). The presence of bacteroids in ovaries from newly emerged flies from pupae received from the Tsetse Research Laboratory at Langford in Britain ruled out the possibility of the microorganisms originating as an infection due to the culture conditions in our laboratory. The bacteroids do not elicit degenerative responses from the host tissues: they were not found to be associated with lysosomes or autophagic vacuoles. Since the viability of the subsequent offspring from our flies was not affected, we can only conclude that these are normally occurring symbionts with some functional significance. Previous studies on oogenesis in tsetse flies[12–14] have revealed no symbionts, but the methods used gave insufficient resolution.

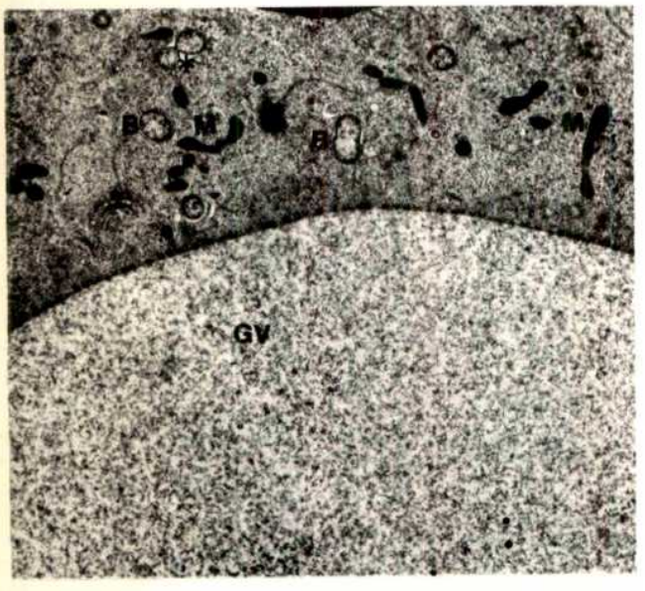

FIG. 1 An electron micrograph of part of a young oocyte from the inactive ovary of a newly emerged fly. Note the numerous bacteroids (B) in the ooplasm, which are clearly distinguishable from the mitochondria (M). A dividing bacteroid (*) is also visible. GV, germinal vesicle. (× 7,000.)

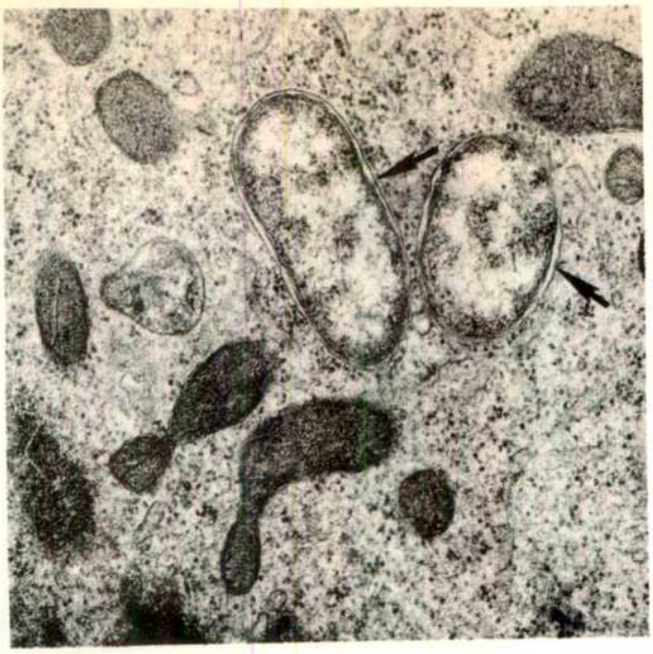

FIG. 3 Bacteroids in the cytoplasm of a nurse cell from a newly emerged female. Note the presence of host membrane (arrow) around the bacteroid. (× 39,500.)

While ovarian symbionts may be important to the processes of oogenesis or fertilisation[15], it is perhaps more likely that these organisms constitute a source for the symbionts of the larval and adult midgut. Certainly such a function is well known in other arthropods[6]. The symbionts present in the nurse cells may be transported through intracellular bridges to the oocyte, where they would be conveniently placed for localisation in the presumptive midgut cells of the embryo. The symbionts of the ovary are similar in structure to those in the midgut mycetome of the adult (Fig. 4), but are considerably smaller. Moreover, the midgut forms appear not to be enclosed in a host membrane[4]. However, the symbionts of the ovary resemble those of the midgut more closely than do the microorganisms reported in the lumen of the milk gland[7].

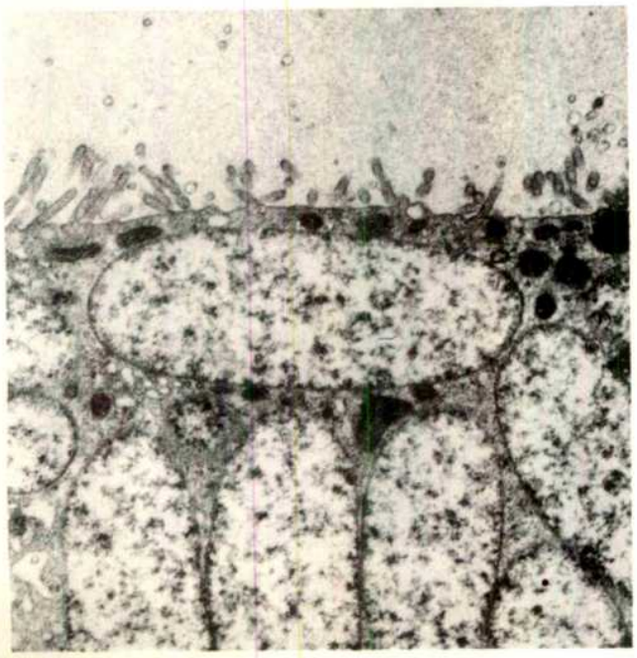

FIG. 4 Bacteroids in the apical cytoplasm of the mycetome of an adult female. (× 13,000.)

Although we do not discount the possible role of milk in the transmission of symbionts to the larva, our findings provide concrete support for transovarian transmission as an alternative or parallel mechanism. This means of transmission from one generation to the next does not require the externalisation of the bacteroids into the lumen of the milk gland, and their subsequent penetration into the cells of the gut of the larva. While the presence of symbionts in the ovaries of the adult, and hence the possibility of transovarian transmission, is clear, a decision as to whether the symbionts are the progenitors of those found in the mycetome of the larval and adult midgut awaits a detailed ultrastructural study of their fate during embryonic development.

We thank Drs T. A. M. Nash and A. M. Jordan of the Tsetse Research Laboratory for flies, and Dr S. S. Tobe who maintained the flies and provided advice. Research at the Institute of Parasitology is supported by the National Research Council of Canada.

Uptake of horseradish peroxidase by frog photoreceptor synapses in the dark and the light

INDIRECT evidence suggests that vertebrate photoreceptors decrease their release of a depolarising transmitter substance in response to the absorption of light. Vertebrate photoreceptors[1–3] and most horizontal cells[2,4] hyperpolarise in response to light and show an increased membrane resistance. In addition, transretinal currents that depolarise receptor terminals also depolarise horizontal cells[5–7]. Finally, magnesium, known to decrease transmitter release in neuromuscular[8] and other synapses[9], hyperpolarises skate[10] and turtle[11] horizontal cells. We now report more direct evidence that the photoreceptors are synaptically active in the dark and that this activity can be diminished by light.

Active synapses can be labelled with macromolecular tracers. This has been established using horseradish peroxidase to study lobster neuromuscular junctions[12]; by work with vertebrate neuromuscular junctions studied with peroxidase[13,14] and dextrans[15]; by investigations of cultured central

FIG. 1 Phase contrast photomicrograph of a thick section of a retina exposed to peroxidase for 60 min in the dark. At R, a rod cell synapse is seen, made dark by its content of peroxidase reaction product; note the thin characteristic stalk (arrows) by which the synapse is attached to the nuclear region (this latter region is not seen at this plane of focus). C indicates a cone cell synapse, also containing reaction product; as expected for this cell type, the synapse is quite close to the nuclear region (N). OS indicates the level of the outer segments. S indicates the level of the synaptic layer. The bar represents 10 μm.

nervous tissue[9], and by studies of neurosecretory systems[16]. The essential findings in these studies and some related work (for review see ref. 9), were that synaptic terminals could be shown to take up tracers into small synaptic vesicles and other membranous structures when stimulated to release transmitters by electrical or chemical means. Uptake into synapses that were not active in transmitter release was slight.

For the present work, isolated frog retinae were prepared by standard procedures and maintained under various conditions of illumination in either Ringer or Na-aspartate Ringer solution[17]. Aspartate depolarises the postsynaptic membranes and thus isolates receptor potentials[18–20]. The retinae were placed in a chamber of an extracellular recording system so that we could monitor the electrical activities of the receptors. Horseradish peroxidase (Sigma Type II) at a concentration of 0.5% was included in the bathing medium. After suitable periods of exposure, the retinae were rinsed briefly in Ringer, fixed in 2.5% glutaraldehyde in cacodylate buffer, cut in small pieces, incubated to demonstrate peroxidase activity[21], postfixed in osmium tetroxide, embedded in Epon and prepared for light and electron microscopy. Cytochemical controls, such as preparations incubated in a peroxide-free cytochemical medium or retinae never exposed to exogenous tracers but incubated in full medium, showed no reaction product.

The synapses of frog photoreceptors appear to be active in the dark. When retinae were maintained in the dark for 30-90 min, extensive uptake of peroxidase by the synapses was observed. This was readily detectable by light microscopy of thick sections cut from the Epon blocks (Fig. 1) where reaction product is seen as dark brown diffuse or granular deposits within the synapses. It was often possible to determine whether a particular synapse belonged to a rod or a cone receptor by focusing up and down carefully, and thus following the cell from the synapse to its outer segment. Furthermore, the position of the nucleus of the cell making the synapse also helped show whether it was a cone or rod synapse. Most rod nuclei are located in the distal layer of the photoreceptor nuclear region while cone nuclei are found in the proximal layer[22]. (Most of the green rod nuclei are also located among the cone nuclei. These cells, however, comprise only about 8% of the receptor population while cones make up about 42% and red rods 50% (ref. 23). In the electron microscope, most, if not all, the synapses from dark retinae were seen to have taken up peroxidase into numerous vesicles (Fig. 2).

When retinae were maintained in the light (for 30–90 min) at an intensity that decreased rod sensitivity substantially relative to cone sensitivity, markedly fewer synapses were observed to have taken up extensive amounts of tracer. It was clear from careful light microscopy that many of the active synapses were of cone cells and many of the inactive ones were of rod cells. (It was impossible to designate all synapses as rod or cone because of such factors as inappropriate plane of section. We are confident, however, that few rods had appreciably active synapses under these conditions.) In the electron microscope (Fig. 3), many synapses were observed to have contents of peroxidase comparable with that found in dark synapses (synapse A) while many others (synapse B), took up little tracer. Synapse A is quite close to its nucleus, indicating that this is probably a cone.

Another procedure used is known to decrease the frog's rod sensitivity relative to that of the cones, but it does not require the continuous presence of light. Retinae were exposed for 5 min to very high intensities of light that bleach about 90% of the visual pigment[24]. The preparations were allowed to recover for 30 min in the dark and then for the first time they were exposed to peroxidase (for 30–45 min in the dark). Under these conditions, the rods of an isolated retina permanently lose sensitivity because they cannot regenerate their visual pigment in the absence of the pigment epithelium[25–28]. Cones, on the other hand, can regenerate their pigment[29] and recover nearly all their sensitivity[17]. The results we obtained were similar to those found in the continuous light condition. In the light microscope, many of the active synapses seemed to belong to cone cells and many of the inactive ones were from rod cells. In the electron microscope, the preparations were essentially similar to the continuous light preparations (compare Fig. 3).

The previous work on tracer uptake by neuronal synapses[9,12–16] strongly suggests that such uptake reflects the membrane rearrangements attendant on transmitter release. As always, the presence of a tracer molecule could conceivably

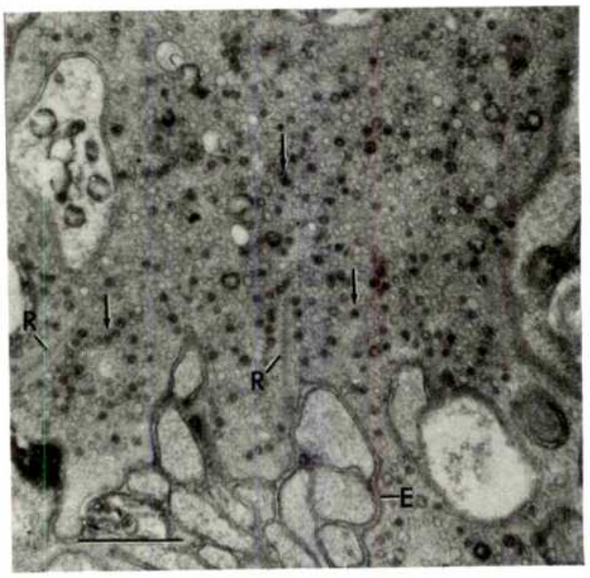

FIG. 2 Synapse from a retina exposed to peroxidase in the dark for 90 min. Reaction product is present in about 35% of the small vesicles. A few labelled vesicles are indicated by arrows; it may eventually prove of interest that some of these vesicles are clustered near the synaptic ribbons (R). Reaction product in extracellular space is seen at E. The bar represents 0.5 μm.

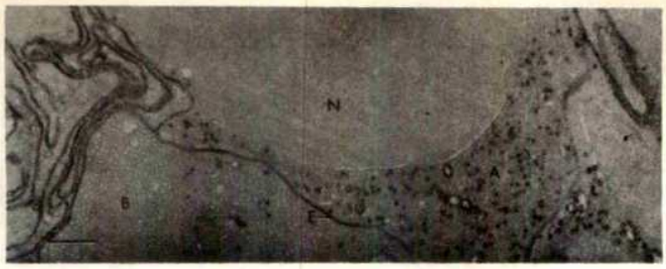

FIG. 3 Synapses from a retina exposed to peroxidase in the light for 45 min. Synapse B shows reaction product at its surface (E) but only 3% of the vesicles are labelled. In synapse A, 30% of the vesicles show reaction product. Note the edge of the nucleus (N) abutting on the synaptic region of A. The bar represents 0.5 μm.

alter the normal behaviour of the cells. However, our electrophysiological recordings indicate that the presence of peroxidase had little or no effect on the receptor responses. In addition, since the rods do not take up peroxidase in the light and bleach conditions, uptake cannot be explained as simply an artefact of the presence of the tracer.

Thus, our findings indicate that, at least in the isolated retinae, the photoreceptors are synaptically active in the dark. On exposure to lights (continuous or brief high intensity) that have been shown to desensitise frog rod receptors[24,30], rod synapses become quiescent but cone synapses remain active. If we make the reasonable assumption that synaptic activity is controlled by membrane potential, then our results are consistent with the evidence indicating that rod receptors are relatively depolarised in the dark and hyperpolarised during continuous light exposure[31,33]. However, more than 30 min after light exposures that bleach substantial rod pigment, we found little or no rod synaptic activity while physiological experiments on skate[34] and fish[35] retinae can be interpreted as indicating that synaptic activity returns fairly quickly to dark levels. Further work on potential changes in the frog retina is needed to determine the time course of changes under the conditions we have used.

Preliminary reports of these findings have been presented already[36,37]. We thank Fe Reyes for technical assistance. This work was supported by a grant from the National Institute of Neurological Disease and Stroke and by a US Public Health Service training grant.

Human lymphocyte-dependent antibody mediated cytotoxicity and direct lymphocyte cytotoxicity against non-HL-A antigens

EXPRESSION of the major transplantation antigens in humans is generally considered to be controlled by the genes of the *HL-A* region[1–4]. Skin, kidney and bone marrow transplants usually survive longer when donors and recipients are HL-A identical than when they are not[5–7]. However, the fact that grafts are still rejected with HL-A identity and negative mixed lymphocyte reactivity (MLR)[8–11] strongly suggests the presence of minor transplantation antigens. The major problem to date has been the development of *in vitro* assay systems to detect these antigens.

Attempts to identify presensitisation of potential graft recipients to non-HL-A antigens have generally failed when they have involved testing for complement-dependent antibody to donor cells[12,13]. On the other hand, there are reports of cytotoxicity, mediated by sensitised lymphocytes from multiply transfused patients, against non-HL-A antigens[13,14]. We have now found that patients who have received multiple transfusions develop lymphocyte-dependent antibody (LDA) as well as cytotoxic lymphocytes against non-HL-A antigens. These responses occur in spite of negative MLR.

Three patients, two males and a female, were studied: two suffered from aplastic anaemia and one from a preleukaemic state with pancytopoenia. They all received multiple blood and platelet transfusions from unmatched

* Parentheses indicate a deduced genotype in a parent who was not typed.
† HL-A typing was performed for families 1 and 2 by Dr P. Terasaki and the NCI Human Histocompatibility Typing Center maintained at Microbiological Associates, Inc. with identical results. Family 3 was typed only by Dr P. Terasaki

TABLE 2 Mixed lymphocyte culture stimulation indices for HL-A identical siblings*

Responder	Stimulator	Ratio†
Patient 1	Sibling	1.1
	Unrelated	5.8
Patient 2	Sibling	1.0
	Unrelated	28.8
Patient 3	Sibling	1.3
	Unrelated	7.6

* MLR was performed as previously reported[16]. There were 2×10^5 responding lymphocytes per tube. Stimulating cells ($2 - 10 \times 10^5$ per tube) were treated with mitomycin C.
† Results are expressed as the ratio of d.p.m. in cultures stimulated with allogenic cells to d.p.m. of cultures stimulated with autologous cells, that is A + Bm/A + Am. A ratio ≥ 2 represents stimulation. Incubation time was 4–7 d and the ratio was determined from the time at which the peak stimulation was achieved with that pair of individuals.

donors and from their HL-A identical sibling. HL-A typing data (Table 1) demonstrated genotypic identity between each patient and sibling.

Cytotoxicity mediated by sensitized lymphocytes and by LDA was measured by rapid release of ^{51}Cr as described before[13,15]. Target and attacking cells were obtained by passing heparinised blood over nylon columns and by incubating nonadherent cells with Plasmagel. Target cells were treated with NH_4Cl-Tris buffer to eliminate red blood cells and then were labelled with ^{51}Cr (200–400 μCi given to 10^7 cells for 30–60 min). To test for direct cellular cytotoxicity, 5×10^4 ^{51}Cr-labelled target cells were incubated with 3×10^6 attacking lymphocytes (1 ml) in 35mm plastic dishes for 4 h on a rocking platform in a CO_2 incubator. To test for LDA-mediated cytotoxicity, ^{51}Cr-labelled target cells were incubated with serum containing LDA for 30 min, and then washed by centrifugation. Target cells (10^4) were placed in dishes with 10^6 normal attacking lymphocytes (1 ml) (test group) or media alone (control group). After 4 h the contents of the dishes were transferred to tubes; 1 ml of cold balanced salt solution + 10% foetal calf serum was added and tubes were centrifuged (800*g*, 10 min). Aliquots were taken for counting of ^{51}Cr release. Immune percentage lysis was calculated by comparing the ^{51}Cr released from target cells during the 4 h incubation with the maximum amount released by freezing and thawing target cells. The following equation was used to calculate immune percentage lysis:

$$\frac{\text{Average test } ^{51}\text{Cr release} - \text{Average control } ^{51}\text{Cr release}}{\text{Freeze-thaw } ^{51}\text{Cr released} - \text{machine background}} \times 100$$

Standard error:

$$\frac{1}{\text{freeze-thaw } ^{51}\text{Cr release}} \left[\left(\frac{\text{variance}}{\text{sample No.}} \right)_{\text{test group}} + \left(\frac{\text{variance}}{\text{sample No.}} \right)_{\text{control}} \right]^{1/2}$$

Lymphocytes from each patient failed to be stimulated in MLR by cells from his other HL-A identical sibling (Table 2). MLR tests were technically satisfactory as demonstrated by stimulation of these patients' lymphocytes by cells from a third party. On the other hand, serum from each of these patients supported LDA-mediated cytotoxicity against target cells from his HL-A identical sibling and against third party target cells from a donor not matched with the patient for HL-A antigens (Table 3). LDA-mediated cytotoxicity against non-HL-A antigens was directly proportional to the relative antibody concentration, and the activity was stronger against unrelated targets. All three sera were negative when tested against autologous freshly explanted lymphocytes (Table 3). These target cells were lysible in LDA reaction as demonstrated with LDA-containing serum from unrelated multiply transfused donors.

The three pairs of donors were tested for direct lymphocyte cytotoxicity, and in each case the patient's lymphocytes lysed ^{51}Cr-labelled target cells from the HL-A matched sibling and from an unrelated donor (Table 4). These attacking lymphocytes were not cytotoxic for autologous targets, thus demonstrating specificity.

We have demonstrated that three patients who were supported by blood and platelet transfusions from their HL-A identical siblings developed LDA against non-HL-A

TABLE 3 LDA-mediated cytotoxicity against targets from HL-A identical siblings

Family	Source of target lymphocytes*	Source of coating serum†	Source of normal attacking lymphocytes‡	Target cell immune damage % lysis ± s.e.§
1	Identical sibling	Media	Father-1	−0.6 ± 1.7
	Identical sibling	Patient-1	Father-1	10.1 ± 1.1

	Non-identical sibling-2	Patient-2	13.2 ± 1.0
	Non-identical sibling-2	Non-identical sibling-2	−0.5 ± 0.9
	Patient-2	Patient-2	0.03 ± 0.8
3	Identical sibling-3	Patient-3	6.4 ± 0.4
	Identical sibling-3	Non-related donor	−1.9 ± 0.7

* There were 5×10^4 target cells per dish. Numbers refer to specific families. Siblings 1*a* and 1*b* were HL-A identical with the patient. Results from family 2 were published in ref. 13.

† There were 3×10^6 attacking cells per dish. Numbers identify specific families.

‡ Damage after a 4-h assay. Values were corrected for 'spontaneous' ^{51}Cr release from target cells incubated in media alone. These spontaneous ^{51}Cr releases varied from 5.6% to 25.1% lysis. Media (Eagle's essential) contained 10% heat-inactivated foetal calf serum.

antigens on their sibling's target cells. In addition, these patients developed cytotoxic lymphocytes against cells from the HL-A matched siblings. Together with two other cases we described before[13], we have now five patients who demonstrated direct cellular cytotoxicity against non-HL-A antigens. LDA and cytotoxic lymphocytes did not mediate damage to autologous target cells, demonstrating the specificity of the assays.

It was not surprising that lymphocytes from each patient were not stimulated in MLR when incubated with his or her sibling's cells, while patients' lymphocytes were adequately stimulated by third party cells; cell donors presumably shared the same HL-A-linked *MLR* genes. This suggests that HL-A-linked *MLR* gene differences are not essential for development of cellular and humoral immune responses to transplantation antigens. In support of this concepts are results reported with humans[17,18], and dogs[19], involving transplants between siblings genotypically matched for major histocompatibility antigens and MLR negative. In the one human pair, a skin graft was rejected by the recipient[17]. In a separate human study, severe graft versus host (GvH) disease developed in the recipient of a bone marrow graft[18]. Likewise, six of sixteen dogs developed fatal GvH disease following marrow grafting[19]. The recipient of the skin graft and the donors of bone marrow in all these cases were not preimmunized by blood transfusions. The possibility that MLR differences are not essential for cellular immune responses does not agree with reports that HL-A-linked MLR genetic differences are necessary for primary *in vitro* sensitisation of human peripheral blood lymphocytes against allogeneic transplantation antigens[20,21]. The studies assessed sensitisation by both MLR and cell-mediated cytotoxicity tests. Perhaps the differences can be explained because our patients were hyperimmunised *in vivo*.

We conclude that cellular and humoral immune responses may develop *in vivo* in the absence of HL-A-linked MLR differences and detectable MLR responses. These responses can be detected by lymphocyte-dependent antibody and by the existence of cytotoxic lymphocytes, both of which react with non-HL-A antigens. These minor histocompatibility differences can be detected *in vitro* by rapid ^{51}Cr release assays. Thus transplantation behaviour across minor histocompatibility antigens *in vivo* can now be correlated with an *in vitro* cytotoxic reaction.

We thank Dr William Terry for advice and encouragement. We also thank Dr John Macdonald, National Cancer Institute Medicine Branch, and Ms Regina Dowling Plasmapheresis Unit, NCI, for arranging blood donations, and Miss Ethlyn Howard for assistance in preparation of the manuscript.

Pial vessels transport of substances from cerebrospinal fluid to blood

CEREBROSPINAL fluid (CSF) is formed in the choroid plexuses, in the ventricular cavities through ependymal walls[1] and in the subarachnoid space[2,3]. Some authors[3,4], consider that subarachnoid fluid production constitutes 40% or more of the total secreted CSF. The formation of this subarachnoid fluid can be attributed to the pial vessels or be considered as a collection of extracellular fluid produced by the parenchymal capillaries, passing to the subarachnoid space through the pial membrane. Endothelial cells of the respective vessels should possess specific transport properties if they produce a fluid which might be of similar composition to that formed by the plexus. Absorption of the fluid and selective transfer of substances from CSF to blood should also be accomplished. The aim of this investigation was to explore which of the two, pial vessels or parenchymal capillaries, was the preferential route.

By implanting a plastic ring on the pial surface, it is possible to create an isolated subarachnoid reservoir where substances under study can be placed[5,6]. By rapidly collecting successive samples from the sagital sinus blood, it should be possible to study the time course of the passage of substances in different experimental conditions[7]. If communication between the subarachnoid cup and the venous pial vasculature were direct, the appearance of a substance in the sinus should be immediate, whereas if the route were from the subarachnoid cup to the brain tissue and then to the parenchymal capillaries, the appearance should be delayed and probably influenced by the varying degree of metabolism or binding of the substance with the tissue constituents.

Mongrel dogs, under nembutal anaesthesia (30 mg kg^{-1}, given intravenously) weighing 12 to 20 kg, were used throughout. For access to the sagital sinus, a lucite adapter with a plastic cannula was tightly screwed into a hole drilled in the skull. The animal was heparinised to allow dropwise blood flow which could be interrupted by clamping the cannula. A plastic ring, 2 cm diameter, was placed on the pial surface of one of the hemispheres, the proximal border of the ring being 0.8 to 1.2 cm from the sinus adapter. The leak-proof plastic cylinder was kept in place by an agar gel without exerting pressure on the brain surface. Merlis artificial CSF[8], *p*H 7.4, was used as a solvent for the tracer materials studied: ^{3}HOH (water), L-^{3}H-phenylalanine and ^{22}NaCl. The radioactivity concentration in the cup varied from 12 μCi ml^{-1} (^{22}Na) to 25 μCi ml^{-1} (^{3}HOH). ^{22}Na was run simultaneously with the tritium labelled isotopes. L-^{3}H-phenylalanine was directly diluted in Merlis CSF ('without carrier', 2 μM L-phenylalanine CSF). The artificial CSF containing isotopes were poured into the cup and thereafter collection of sinus blood in successive tubes was made at intervals varying from 1 to 60 s. When the lapse was longer than 10 s, blood was collected only the last 10 s of the interval. The longest experiment lasted 10 min. Blood and cup samples were deproteinised with absolute ethanol and after centifugation an aliquot of the supernatant was used for radioactivity counting in a liquid scintillation spectrometer[7].

The results were expressed as blood to cup radioactivity concentration ratios against time, as shown in Figs. 1 and 2. Several experiments were performed in each animal, with a rest interval of at least 30 min between runs. Because of the varying characteristics of pial vessel surface in the animal preparation, blood flow, and so on, it is more convenient to introduce experimental changes in the same animal where adequate controls could be run. Blood pressure in the femoral artery and flow from the sinus cannula were measured during the experiments as an index of normal circulation. Some animals showing brain oedema with protrusion of the cortex through the pial cup, were discarded.

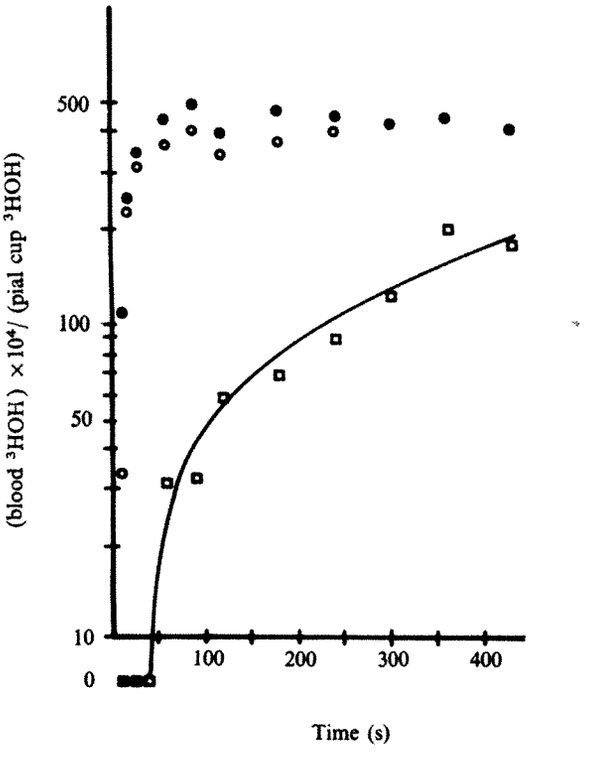

FIG. 1 Appearance of ^{3}HOH in sagital sinus blood. At zero time artificial CSF containing the isotope was poured into a subarachnoid cup and blood was collected in successive samples. ○ and ●, Two experimental runs in the same animal with the pia intact. A third run (□) was made after removing the pia, placing ^{3}HOH on the naked cortex. In this case radioactivity was not detectable in the samples corresponding to the first 30–50 s. Applying a one-compartment analysis, the calculated $t_{1/2}$ for the controls were 11 and 7 s, and for the run 'without pia', 347 s.

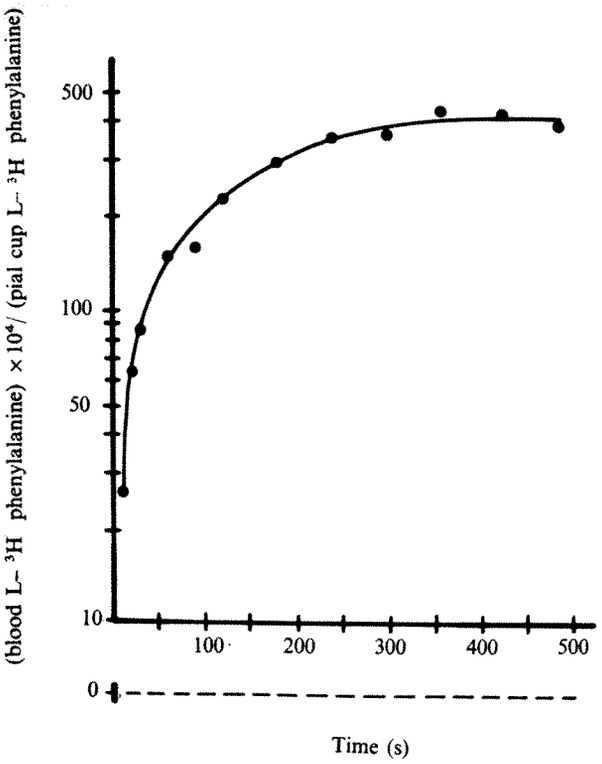

FIG. 2 Influence of removal of pia mater on the passage of L-^{3}H-phenylalanine from a subarachnoid cup to blood. With the pia intact (—), the passage is relatively rapid ($t_{1/2}$ = 92 s), whereas without pia (– – –) no significant radioactivity was found in blood throughout.

TABLE 1 Compartmental analysis of the tracer appearance curves

^{3}HOH		L-^{3}H-phenylalanine		^{22}Na
$t_{1/2}$(s)	r	$t_{1/2}$(s)	r	$t_{1/2}$
8	0.91 (9)	19	0.99 (7)	∞
5	0.99 (4)	14	0.97 (8)	∞
18	0.99 (10)	20	0.99 (11)	∞
20	0.99 (11)	22	0.96 (12)	∞
15	0.99 (14)	35	0.91 (13)	∞
11	0.99 (3)	92	0.99 (7)	∞
7	0.99 (3)			
28	0.99 (4)			
14	0.99 (4)			

Results of the linear least square regression fit for each experiment are given as $t_{1/2} = 0.693/\lambda$ (see text). The correlation coefficient r is followed by the number of experimental points in parenthesis. For ^{22}Na $t_{1/2}$ was considered infinity as no blood radioactivity was detected during the experimental time. Each result corresponds to one animal.

The rate of ^{3}HOH appearance in the sinus blood is fast during the first 30–50 s as shown in Fig. 1 ('with pia') probably indicating the passage of ^{3}HOH through the pial vessels from the cup to the pia and then to the blood. ^{22}Na placed simultaneously in the cup did not appear at all in the venous blood, indicating that pial vasculature is not permeable to Na^+. These results are similar to those obtained with the same cation introducing the tracer in the carotid[7]. The presence in parenchymal capillaries of a barrier impermeable to sodium but highly permeable to water, is indicated.

The interpretation that the way of transport is through pial vessels during the rapid ascending part of the curve in Fig. 1 ('with pia') is reinforced by experiments in which the pia mater was removed after application of $AgNO_3$ 5% solution for 5 min. It has been demonstrated that such a procedure does not affect the viability of the underlying tissue[6]. With the cup on the naked cortex another ^{3}HOH run was performed (Fig. 1, 'without pia'). No ^{3}HOH appeared in the venous blood until the 60 s sample. In the absence of the pial vessels the only route available after 60 s would be from the cup to the brain tissue and then to the blood.

Compartmental analysis of the data was performed assuming a one-compartment system (pia or brain tissue) with a constant input concentration which is the CSF in the pial cup. It can be seen in Fig. 1 that, as expected in this model, the blood concentration, b, raises approaching a plateau value, b_{max}. Therefore, a linear least-square fit of the experimental data was made according to the equation: $\ln(1 - b/b_{max}) = -\lambda t$. For data 'with pia' in Fig. 1, $t_{1/2}$ of 11 and 7 s were calculated with a correlation coefficient r of 0.99 for both. For the run 'without pia', b_{max} was assumed to be equal to that in the control experiments and the estimated $t_{1/2}$ was 347 s, $r = 0.95$. All experiments were analysed in the same way, showing high correlation coefficients. The data are summarised in Table 1. The $t_{1/2}$ for ^{3}HOH was between 5 and 28 s, with an average of 14 s. For ^{22}Na experiments in which no radioactivity could be detected, the $t_{1/2}$ was considered to be infinity.
